HIGH RESOLUTION ELECTRON MICROSCOPY

CUK- H06839- 277- RP407

When in London do as the Romans did-settle on the Barbican. (It's the perfect place for a conference.)

It's a long time since the Romans left. (About 1,500 years, in fact.) But you can still see traces of their occupation–including remains of the original Roman city wall.

The Barbican Centre is located in the heart of the City of London. So it's surrounded by centuries of history and culture plus the bustle and excitement of one of the world's leading financial communities.

The Barbican Centre itself, however, is among the most modern and well equipped conference centres available.

There's a spacious conference hall. A variety of lecture theatres, seminar and committee rooms. A Film Theatre–with the most advanced audio-visual equipment. The Barbican Theatre. Interpretation facilities for six languages. A display and exhibition area. Plus a plentiful supply of bars and restaurants.

The Barbican caters for cultural appetites, too. The Royal Shakespeare Company will have its permanent home there. So will the London Symphony Orchestra. And the Guildhall School of Music and Drama. There's an Art Gallery. A Sculpture Court.

In other words, it's as civilised a forum for a conference as even the Romans could have dreamed of.

So, if there's anything more you'd like to know about the Barbican, just contact our Conference Sales Director.

And don't worry. She speaks English. Not Latin.

The Barbican Conference Centre, 11 Cromwell Tower,
The Barbican, London EC2Y 8DD, England. Telephone: 01-638 4141.

The Barbican Conference Centre

A display and exhibition area with a total of 64,000 square feet (5,500 square metres).

The Barbican Conference Hall comfortably seats 2,000 delegates.

A variety of lecture theatres, seminar and committee rooms to take anything from 5 to 265 people.

The Film Theatre seats 275 people.

The Barbican Theatre seats 1,150.

Raven Press

JOURNAL OF CARDIOVASCULAR PHARMACOLOGY

Editors-in-Chief: J. Koch-Weser and W. Pettinger

An international, multidisciplinary journal devoted to furthering the exchange of new information on cardiovascular pharmacology.

Published bimonthly beginning January 1979.
Volume 1: $48.00 U.S.A.; $56.00 Elsewhere

METHODS IN PROSTAGLANDIN RESEARCH

(Advances in Prostaglandin and Thromboxane Research, Vol. 5)

Editor: J. C. Frölich

A practical manual for the laboratory, this book describes in full detail methods that are currently in use in the discovery, identification, and quantitation of prostaglandins, thromboxanes, prostacyclin, and their precursors and metabolites. The book is extensively cross-referenced and indexed, making it a source of ready reference.

250 pages (1978) $31.20

ADVANCES IN CYCLIC NUCLEOTIDE RESEARCH (Vol. 10): CURRENT METHODOLOGY

Editors: G. Brooker, P. Greengard, and G. A. Robison

This is a complete and detailed review of the current methodology used in studying the cyclic nucleotides and their biological effects. The detailed instructions for the methods, including the needed materials and discussions of problems and techniques to check assay validity, will be invaluable.

250 pages (1979) $31.20

GLUTAMIC ACID: BIOCHEMISTRY AND PHYSIOLOGY

Editors: L. J. Filer, Jr., S. Garattini, M. R. Kare, W. A. Reynolds and R. J. Wurtman

This volume reviews the sensory and dietary aspects of glutamate, its metabolism in mammals, its role in the central nervous system, an evaluation of its safety and experimental application, and clinical aspects of glutamate utilization.

425 pages (1979) $36.40

NEUROCHEMICAL MECHANISMS OF OPIATES AND ENDORPHINS

(Advances in Biochemical Psychopharmacology, Vol. 20)

Editors: H. H. Loh and D. H. Ross

This volume provides a comprehensive review of the rapidly expanding field of opiate reasearch and the current state of our understanding of the neurochemical mechanisms of opiate and endorphin actions.

570 pages (1979) $51.35

Advances in Cyclic Nucleotide Research, Volume 9

THIRD INTERNATIONAL CONFERENCE ON CYCLIC NUCLEOTIDES

New Orleans, Louisiana, U.S.A. July 17-22, 1977 ~~R506~~ RP407

Editors: W. J. George and L. Ignarro

SECTION HEADINGS: Adenylate cyclase / Cyclic GMP and guanylate cyclase / Protein kinases and phosphatases / Phosphodiesterase / Muscle function / Carbohydrate and protein metabolism / Central nervous system function / Proliferation / Special cell functions / Immunology and immunochemistry / Calcium and secretion / Abstracts / Subject Index.

831 pages (1978) $83.20

JOURNAL OF CYCLIC NUCLEOTIDE RESEARCH

The rapid publication of studies devoted to hormonal and physiologic regulation, reviewed by experts in the field, assures a high level of currency and excellence. In addition, each issue contains 20-25 pages of citations based on weekly computerized scanning of worldwide literature by the ISI.

Bimonthly. Vol. 5 (1979)

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258,** 1 (1975) and **264,** v, 11 Nov. (1976).

6 September 1979

UNCSTD was a modest success

Developing countries have been told to take science and technology much more seriously — and have been given a little help to do so. Much depends on how they use the first $250 million.

AS the couple of thousand delegates who have attended the UN Conference on Science and Technology for Development (UNCSTD) in Vienna disperse, most will be asking themselves whether the conference was a success or a failure. For some, who came with very specific objectives such as to do business with other delegates, the answer will be equally specific. But for the vast majority who came with rather more diffuse expectations the answer will be complex. In the end, of course, no real assessment can be made until we can apply a historian's eye to it and ask whether the whole range of activities associated with UNCSTD — the national discussions, the regional conferences, the involvement of non-governmental organisations (NGOs), the pre-conference negotiations quite apart from UNCSTD itself — has significantly quickened the pace of development. And for that the historian must be sure that what 'development' means is how people themselves want to share in the intellectual and physical resources of the world. This means freedom not just for developing countries to design their own development strategies, free from the dictates of the developed world and its technology-salesmen. It also means freedom for the people of developing countries to choose not necessarily to go along with the development strategy worked out for them by a Westernised elite in their capital city. It means freedom for individuals to go their own separate ways in pursuit of individual development. So the influence of UNCSTD is hardly to be measured in a short space of time by adding together a few numbers.

In tangible terms, however, UNCSTD will leave behind a mountain of national reports, regional summaries, discussion papers — and a handful of documents debated at the conference itself. We report on subsequent pages on how these documents (the Programme of Action and a paper on science, technology, development and the future) were negotiated over the two weeks. Since the UN rule is to proceed by consensus if at all possible, they are necessarily broad generalisations and in many cases contain exhortations that individual countries will simply be unable to act upon. Negotiation is carried out by blocs and the interests of individual nations sometimes have to be surrendered for reasons of solidarity. Most publicity at the conference centred on the difficulty that the European Economic Community had in keeping to a unified position, particularly on questions of new financial support. But there is no reason to suppose that the Group of 77 (the developing nations), for which Tunisia acted, was any more united beneath the surface. The Group comprises nations as different as India, Brazil, Venezuela, The Gambia and Nepal, and so the diversity of need is enormous.

What they agreed upon

In the Programme of Action, delegates agreed, in essence, on the following:

- that the debate on the terms under which technology is transferred from the developed to developing world was not going to be resolved at UNCSTD; there are wide differences over questions of confidentiality, restrictive practices, the relevance of existing international agreements (at a time when the Group of 77 is promoting the New International Economic Order) and so on;
- that developing countries be exhorted amongst other things to:
  - formulate national science and technology policies;
  - make these policies as wide-ranging as possible;
  - establish policy-making bodies;
  - set up information networks, standardisation agencies, specialised institutions and so on;
  - formulate a technology transfer policy;
  - promote scientific associations, extension services, media reporting of science;
  - develop manpower policies and study the brain drain;
  - coordinate all this, and much besides, on a regional and international level;
- developed countries should help the developing countries along by supporting a new, additional funding facility under the aegis of the United Nations Development Programme. They should be invited to make pledges totalling $250 million over the two years to 1981. This facility would finance a broad range of activities aimed at strengthening the endogenous scientific and technological capacities of developing countries. The Group of 77 had initially asked for $2 billion per year by 1985;
- that a new UN inter-governmental committee oversee the implementation of the Programme of Action, and
- that a global information system be established.

In short, developing countries have been told to take science and technology much more seriously at a governmental level and to establish all sorts of new institutions. But the funding for it will very largely have to come from their own pockets. $250 million is not a large sum when divided amongst all potential applicants. And furthermore there is a strong feeling both in developed countries and in the poorer and smaller developing countries that when it comes to sharing out the money, the larger and relatively richer countries of the Third World will dominate the handouts, because they are more easily able to put up an impressive case, already having the right beginnings.

Role of scientists

The Programme of Action was almost entirely debated at the diplomatic level. How then did scientists and technologists fare at the conference? There had been an ambiguity about their role in UNCSTD right from the word go. Naturally it was not to be just another scientific conference. But how deeply were scientists to be drawn into participation in Vienna? It has been no secret that Joao Frank da Costa, the Secretary-General of the conference has had little enthusiasm for their involvement, and certainly issues such as transfer of technology, and institutional and funding arrangements within the United Nations system were ones on which relatively few scientists might have an informed view. On the other hand, scientists might have extremely clear views on global information networks, means of strengthening facilities in the developing world, research priorities and so on. In the event, however, the ambiguity persisted right to the end of the conference, and left many scientists disillusioned.

One reason for disappointment could have been the variability in the delegations. Some were manned almost entirely by civil servants, others carried a professor or two and a very few (such as West Germany, Austria, France and the United States) made any serious effort to be multi-dimensional by incorporating politicians, academics, industrialists and trades-unionists. There was thus a feeling amongst scientists that they did not constitute a critical mass capable of making their presence felt. This sentiment undoubtedly coloured the discussions in the working group on science, technology, development and the future. Under certain circumstances it would have been possible for this working group's report to have provided the perfect technical counterbalance to the administrative and structural Programme of Action — in effect presenting a pair of papers outlining possibilities and how they might be achieved. In practice this was not to be.

Some of the responsibility for this must undoubtedly be placed on ACAST, the UN's Advisory Committee on Science and Technology. The committee hastily put together a colloquium of 300 scientists in Vienna for the week before UNCSTD. Creditable as such an occasion may have been (and there were a majority of developing-world scientists at it), it undoubtedly siphoned much of the scientific interest away from UNCSTD. And since the working papers for it were prepared by the UN's special agencies, the colloquium already had the veneer of a UN activity before it started. Its final report merely confirmed this, being the sort of document that would be very acceptable in UN circles but which lacked a sense of novelty or character.

The UNCSTD working group started off by falling into the trap of wanting to submit a similarly dull document. But eventually a small group of scientists, clearly horrified at what they were in danger of having to put their name to, forced at least a modest revision (after the years of preparation and millions of dollars poured into UNCSTD, the group's activities were heavily curtailed by lack of time!). Ultimately the report did give a more satisfactory indication of how science and technology could contribute — with particular reference to the need to involve the young and to make positive efforts to encourage women. The role of the United States delegation was crucial — even during late-night negotiating sessions when almost every other delegation was either absent or fielding one representative, the US team would be up to ten in number.

Modest momentum

The cause of development is ultimately in the hands not of delegates to conferences but of politicians apportioning resources and of those at the cutting edge. Has enough come from UNCSTD to give them new direction, support and drive? The Chinese at UNCSTD produced a very apt proverb "don't add yet more flowers to the bouquet; send more charcoal in snowy weather". Will the conference be remembered just for verbal bouquets, or are developed countries prepared to send more tangible help? The level of financial support over the next two years leaves the question open, although the establishment of the funding facility itself must be regarded as a modest step forward in international collaboration. But much depends on just how effectively developing countries put together their proposals in the coming months. It would be easy to spend the money on large capital-intensive projects — grandiose new universities and research laboratories lavishly equipped with equipment but short on running expenses and staff, particularly at the technician level. By 1981 such demands could already have given a bloated and inappropriate image to the whole project. It is better that developing countries (and particularly the poorer developing countries) take the opportunity slowly and thoughtfully to lay down the foundations of a real science and technology policy. Much of the money would be better spent on encouraging communication and discussion than in bricks and mortar.

The outcome of UNCSTD has never been seriously in doubt — the Group of 77 have had to sacrifice their rosier dreams, developed countries have had to make some relatively minor concessions. What matters now is that the modest amount of momentum acquired is not squandered in the years ahead.

A slightly bolder approach

As long as *Nature* has existed, letters reporting important scientific advances have formed the backbone of the journal. The length of these communications has grown steadily with the years as scientists have felt under greater pressure to give sufficient detail to allow a critical evaluation, but their style has remained remarkably unchanged.

We are often asked why we do not fall into line with almost every other journal and publish an abstract with each letter — and our answer has been that we have tried to preserve in the letters section the sort of directness that people achieve when writing to each other. But we go on to add that there is nothing to prevent anyone writing a first paragraph that encapsulates the whole story — background, summary of the work done, consequences; something more valuable than an abstract because it gives context.

For the past few years we have gradually been trying to persuade authors to improve their first paragraphs, if necessary with some help from our sub-editors. Now we take the experiment a bit further. From this week's issue, the first paragraph of each letter will be printed in a bolder face. We hope this may provide some little help to those very many of our readers who turn to *Nature* to keep in touch with a wider range of science than their own specialisation. We hope too that our authors will be encouraged to put even more thought into getting the first paragraph right. And the writer of this leader might practise what he preaches. □

UNCSTD w agreed

isions were agreed at the session of the United Nations on Science and Technology ment which ended in the al hours of last Saturday morning for was to set up a new inter tates of committee on science a mend the development, open al system for the UN. The seco development establishmen of this are being science a an interim fund based and, ributions, with an initial $250 million for the two 980–81. Both these decisions ications of the Group of 77's demands.

e Group of 77, for example, had ginally proposed that the intergovernmental committee be set up by, and report back to, the General Assembly of the UN. But the US had insisted that the committee be established by the UN's Economic and Social Council (ECOSOC).

A compromise was suggested by the Common Market countries and eventually accepted by the conference, along lines drawn up by the British delegation. The new committee will be set up by the General Assembly, but it will report back to the General Assembly through ECOSOC. And the latter, while not permitted to alter the reports, will be able to comment.

The new committee will play an important role within the UN system. How effective it will be will depend on factors such as the strength and status of the support it is given from the UN, which is yet to be decided. One of its main purposes, according to the wording of the final conference decision, will be to "help the General Assembly formulate guidelines for harmonising the policies of the United Nations system in regard to scientific and technological activities".

Specific responsibilities will include: identifying priorities for activities within the programme of action agreed by the conference (now referred to as the Vienna programme of action), preparing a plan for carrying out the programme, and monitoring activities and programmes related to science and technology within the UN system.

A particularly important function of the committee will be to "give directives and policy-making guidance" to the new financing system which the conference proposed that the UN should establish (an earlier proposal from the Group of 77 had been that the committee should "direct" the way that the *financing* system was operated, *but this* language was rejected as too strong).

The financing system agreed is considerably less than the original demand of the Group of 77. This was for a target of two billion dollars by 1985 and four billion dollars by 1990 reached through "automatic" contributions mainly from developed countries.

The main opposition from the developed countries to this proposal was based more on the manner in which contributions were to be made than on the size of the fund. Almost all objected to the idea of "automatic" contributions based on factors such as the balance of trade in manufactured goods — a type of international tax which was strongly resisted — and it was agreed that at least initially all contributions will be voluntary. Other countries, in particular various members of the EEC, were initially opposed to the idea of a fund at all but were eventually convinced to accept the general consensus.

The purpose of the proposed global financial system, according to the conference resolution, will be to "finance a broad range of activities aimed at strengthening the endogenous scientific and technological capacities of developing countries and, in particular, assist in implementing the programme of action".

It was agreed by all conference participants that factors to be taken into account in determining the nature and level of the system's resources should include: the asymmetry of technological capacity between developed and developing countries, the need for predictability and continuous flow of financial resources, the need for substantial resources additional to those existing within the UN system and finally the need for untied external resources.

Since it will take some time to make the arrangements for this financing system, an interim fund, to be administered by the United Nations Development Programme, will be created: and a target for voluntary contributions to this fund has been set at "no less than $250 million" over the two years 1980 and 1981.

A conference will be held before the end of the year at which countries will indicate how much they are prepared to contribute to the interim fund. The main potential donors are the US and Saudi Arabia, with promises from France and a number of smaller European countries. Precisely how the interim fund will be spent remains to be worked out. But it is thought that most of it will go towards helping to build up scientific infrastructures in developing countries.

David Dickson

What scientists did in Vienna

WHILST there was no doubt that the main focus of attention at UNCSTD would be the debate over the Programme of Action, with its associated battles over institutions, money and so on, it was planned that there would be a parallel session to use the assembled scientific and technological expertise to good effect. This session had two fields to look at: new science and technology for overcoming obstacles to development; and science and technology for the future. The working group was chaired by M. Malitza of Romania.

The group had at its disposal national papers, together with two specially commissioned studies and the reports of several conferences. It also had freshly to hand a report from ACAST, the UN's Advisory Committee on the Application of Science and Technology which had met in Vienna the previous week.

The working group (which comprised as many delegates as cared to show up) always seemed to be loaded with disadvantages. It did not start meeting till the fourth day of the conference, and then in a building not within walking distance of the main conference centre; it was presented with a bland ACAST report which seemed to convince the working group that its report should be equally platitudinous; and whilst a few delegations (France, Germany, Austria, United States in particular) had a good complement of scientists and technologists, many could field at most one, more often none at all.

The first draft of the report reflected

these weaknesses. The United States, which had not been one of the 6 members of the drafting group and which claimed it was having difficulty in getting its views considered, was particularly severe in its strictures that the report lacked 'soul'. As one of its delegates put it, "we have put a big effort into this conference; how can we defend this document to our scientists and technologists back home?" The British, too, were voicing concern both publicly and privately that "with all the expertise here in Vienna" nothing more helpful was emerging for consideration in planning future development programmes.

Certainly much of the document merely repeated the same general principles as were being negotiated more formally in the Programme of Action elsewhere. But by this stage there was not enough time left to start again from scratch. Nor would many developing country representatives have been pleased at the prospect, as they were more in need of a general statement of principles to put to the government back home rather than a 'soulful' document.

In the event, and amidst much lobbying by the US, a second draft was produced which left the Americans moderately satisfied without causing problems amongst developing countries. Some of the key points are outlined below.

Science: 'Science policy should be mainly linked to long term objectives'. 'Science and technology . . . should be consistent with national aspirations and objectives'. 'Science of the future must include in its concerns the uplifting of the welfare of the total human being' (the first version had contained the phrase 'basic science should be left free to follow its own internal dynamics').

Obstacles: 'One of the most urgent questions is disarmament . . . more effect should be given to analysing in what ways ongoing research and technical application now directed towards war could be adjusted for peaceful applications'. 'The brain drain of the most skilful scientists and technologists from developing countries creates a serious obstacle to their own scientific and technological development . . . developed countries should assist by actively discouraging a brain drain from developing countries'. This last phrase was concocted as an alternative to the more loaded phrase 'should assist by not enticing scientists and technologists from developing countries', to which some developed countries took exception. But at least one delegate was wondering privately whether 'discouraging' the brain drain did not contravene agreements on the free-flow of scientists.

The United States would additionally have liked a reference to the population problem, but could not get a consensus.

Objectives: 'All countries should develop endogenous capabilities to assess the trends of science and the consequences of technological options'. 'Developing countries have to carry out their own studies of global problems so as to bring their own perspective to bear on the world *problematique.*' 'Goals include overcoming poverty and seeking ways to reduce the disparities that exist between developed and developing societies in, for example, life expectancy, infant mortality and education'. A stronger version speaking of 'halving by the year 2000 the disparities' could not attract a consensus.

Resources: 'As concerns R and D activities in developing countries, every effort should be made by the world community to raise the level of these activities from the present very low level to a substantially increased level. It was the considered view of many delegations that a more quantitative goal should be set and they felt that this should be of the order of 20% to 25% of global world research and development expenditure by the year 2000'. Countries such as India and Bangladesh were keen to have a target, but there were doubts amongst some countries about the reasonableness of these targets or even the precise definition of the terms used.

Action: The building up of endogenous capabilities requires 'massive expansion of the educational system in order to provide access to primary, secondary, technical and higher education to most, if not all, the populations, male and female equally'.

Governments in developing countries should provide support both for existing and new centres of excellence 'dedicated to both basic research and applied research of relevance to their societies'.

Scientists in developed countries 'should be encouraged and helped by their governments to take a more active interest in solving problems in developing countries . . . exchange of scientists and technologists between developed and developing countries should be encouraged . . . informal communications between scientists based on mutual interest are also among the powerful instruments which can be used to help in problem solving'.

Specifics: The working group made sure, in a footnote, that just about every branch of science and technology with the remotest relevance to development received a mention. But it also identified in the main text some rapidly developing fields such as information technology, non-conventional generation of energy (including fusion), biotechnologies and marine sciences.

Women and young scientists: 'Technological development often affects men and women differently and the intro-

0028-0836/79/360004-01$01.00

duction of new technologies has tended to have an adverse impact on the latter, thereby lessening their earnings and social status. It is therefore of the utmost interest to society that in future the full participation of women be ensured in the planning and setting of priorities for research and development as well as in activities relating to the design, choice and application of science and technology for development. They should also be provided with equal access to scientific and technological training and professional career opportunities'.

'Rapid development of science and technology throughout the world will depend in part on the younger men and women who can be brought into these fields, involved in decision making bodies and given full opportunity to use their intelligence and skills'.

Institutions: 'There is a need to restructure and strengthen the international scientific and technological system and the role of international intergovernmental organisations in such a way as to permit such organisations to act as effective instruments in satisfying the priority objectives of member states'.

'An appropriate UN body on science and technology, and other UN agencies competent in this matter' should make recommendations regarding changes in the structure of science and technology to 'service the needs and problems of the peoples of the world, with special regard to the needs of developing countries'. Originally this recommendation spoke only of the new intergovernmental committee that was being established elsewhere in the conference, but the Soviet delegate, in a rare intervention, asked for the involvement of other UN agencies. This possibly keeps the door open for UNESCO and ACAST, both of which had been widely thought to have lost considerable influence as a result of this conference.

David Davies

EEC countries attempt to speak with one voice

ONE of the most significant consequences of the UNCSTD conference is that, for almost the first time, the nine member countries of the European Economic Community were required to speak with a single voice on the appropriate international policies for applying science and technology to development.

At times, EEC maneouvring to achieve this unity resembled those of a cox-less, novice rowing-eight (Luxembourg played a relatively minor role in the negotiations), with everyone heading roughly in the same direction, but with substantially different ideas about commitment and timing. Furthermore, the political requirement for solidarity during formal negotiations with the developing countries meant that many harsh words were said to colleagues behind closed committee doors.

The outcome, however, was at least a partial victory for political cohesion. And this will inevitably have important consequences for the future role played by EEC countries in encouraging particular forms of economic and political development in the Third World.

The pressure to speak with a common voice added a third political factor to the two which have traditionally dominated national discussions of foreign aid policy: on the one hand, the domestic implications, both political and economic, of spending public money on foreign aid, on the other, the international gains to be made by spending this money in a particular way.

A fourth factor played a less explicit, but no less significant, role during the conference negotiations. This was the knowledge that the US had committed itself to ensuring the approval of an interim $250 million fund, with particular executive responsibilities given to the United Nations Development Programme, and investigating the setting up of a long-term international funding system for science and technology for development.

Caught between these four different sources of political pressure, each member country of the EEC was forced to weigh up their relative importance in its own particular circumstances — and decide its negotiating strategy accordingly. At the one extreme Denmark had, at the beginning of the conference, surprised some of its EEC colleagues by advocating immediate commitment to the US-backed package. Compromise was "imperative" to make UNCSTD successful, the Danish Minister for Foreign Affairs, Mrs Lise Ostergaard, told the plenary session.

Similar indications of support came from the Netherlands and Italy. Holland was eager for domestic political reasons not to appear to be backing away from its reputation for generosity in foreign aid, despite economic difficulties.

In contrast, the three major economic partners in the EEC — Britain, France and Germany — each had different reservations about the US-backed package. Britain's position was made clear by the Minister for Overseas Development, Mr Neil Marten, who told the conference that recent drastic cuts in public spending meant that Britain had no money to contribute to any new fund, and that in any case Britain had "serious doubts" about the value of any new financial mechanism or the separation of funds for science and technology for development.

At the same time, however, the British delegation was keen to maintain the political unity of the EEC's negotiating positions and not to be seen as the only country which was sticking out against a consensus.

Germany's position was more complicated. Politically it agreed with the US's view about the need for "cooperation" rather than "confrontation" in economic relations with the developing countries, and about how science and technology agreements can help achieve this goal. It also accepted the need for EEC unity, and could not complain about lack of funds.

For domestic political reasons, however, the German government was reluctant to provide funds to a programme whose precise activities had not been spelt out in detail. It tried — unsuccessfully — to get the EEC to back the idea of contributing directly to a World Bank research programme on renewable energy resources for developing countries.

Finally France, the maverick in the group, was happy to be seen increasing its foreign aid contributions, but less happy about a sectoral fund inside the UNDP. The French annoyed some other EEC delegation members by announcing to them two days before the end of the conference its opposition to the new fund.

Despite such divergences of opinion, by the end of the conference a consensus had been reached to support the US/UNDP package in principle (see page 2). At the closing session, however, it was publicly acknowledged that there remained differences between the EEC members. Speaking on behalf of the whole group as current president of the EEC, the head of the Irish delegation said that six countries — Belgium, West Germany, France, Ireland, Luxembourg and Britain — wished to make it clear that they maintained "their well-known reservation on the efficacity of any sectoral fund for science and technology for development". However, in the interests of achieving a consensus, the statement said, these six countries had not opposed the arrangements for an interim fund, once it had been established that the contributions would be on a voluntary basis.

No-one within the EEC delegation was entirely happy with the outcome. But it was generally accepted that, given the pressures under which the group was working the outcome as a political exercise was fair.

Whether the result will be of overall benefit to the developing countries is another question. Some EEC delegates point out that by agreeing to accept a consensus, some countries adopted a more conciliatory position than they might otherwise have done. Developing country critics, however, also argued that through such consensus-building, countries which might otherwise wish to adopt a more radical stance in their general approach to north-south relationships might be persuaded against doing so.

Very high radiation levels found in Swedish houses

FOLLOWING the discovery of extremely high concentrations of radioactive radon daughter elements in Swedish houses, a government committee has proposed measures to allow maximum concentrations far higher than would be internationally acceptable. The radon producing the daughters derives not only from radium in the soil and rock on which the houses are built, but also from radium in building materials.

The immediate cause of the high levels recently recorded, however, is energy-saving. Enthusiasm for energy conservation has led many people to tape over their windows to keep the warmth inside; consequently ventilation rates have dived. With a ventilation rate of one air exchange every two hours, even the worst radon daughter levels are greatly reduced; but some of the houses measured have had only 0.2 air exchanges every two hours.

To overcome the conflict between energy saving and health, the committee suggests the installation of air exchangers in which the outgoing air would warm up the incoming air. Discussions are currently being held to decide how much financial assistance could be paid to house-holders for the necessary alterations, but at the moment it looks as though the amount will be small.

From the radon point of view, the worst building material used in Sweden is aerated concrete made from alum shale. Its manufacture was banned in 1974 for this reason, but it had been a popular building material for 45 years. At the other extreme is wood which contains practically no radium. Ironically enough, the houses whose high radioactivity led to the committee of enquiry were built of wood — but constructed on slag heaps left after the mining of alum shale. Only a small proportion of risk houses have so far been identified, and campaigns are being organised to find others. Current estimates of the numbers of houses that will have to be altered run as high as 15,000.

The International Committee on Radiation Protection recommends that no member of the general public should be exposed for many years to an annual dose equivalent of more than 1 millisievert (mSv) of radiation, excluding natural background and medical sources. This level is estimated to give a lung cancer rate of one person in every thousand exposed for 60 years. There is as yet no internationally-agreed level for exposure to radon in houses. In the average Swedish house, the concentration of radon daughters gives a dose equivalent of 3 mSv/yr, assuming a person spends 80% of time indoors — and the worst cases found in the present investigation are as high as 100 mSv/yr. "If nothing is done, our present building situation may cause up to 1100 cases of cancer in about 30 years", says the Director of the Radiation Protection Institute, Professor Bo Lindell.

The committee proposes that nobody in existing buildings should, over the next five years, be exposed to a radon daughter level of more than 2000 bequerel (Bq) year/m^3, a total dose equivalent of 285 mSv over 5 years. Existing houses should be altered before their inhabitants have received this total dose. This exposure will, it is estimated, mean that three people in every hundred will develop lung cancer after 60 years. As far as new buildings go, the committee proposes radon daughter concentrations of 70 Bq/m^3 (9 mSv/yr) and at this exposure level, one person in every hundred will develop lung cancer after 60 years. According to the committee, these dose rates are the best that can be achieved at the moment, given the level of radioactivity in Swedish rock, soil and building materials.

The number of people who will develop cancer because of the high radon daughter levels may however be less than these estimates. According to a spokesman at the Radiation Protection Institute, current research into the risks of contracting cancer at certain concentrations of radon daughters shows that the risks to the ordinary man may have been over-estimated. The risk estimates are based on studies of uranium miners, the concentrations around miners who developed cancer being extrapolated to the ordinary population. But these studies did not take into account the fact there is always more particulate matter in the air in mines than in ordinary houses. As radon daughters enter the body attached to airbone dust, the risk to the general public may have been overestimated.

Wendy Barnaby

Women in science: some improvement, but still a long way to go

There has been a considerable improvement in the status of women PhDs in academic science over the past decade, but further substantial gains are still needed before equal opportinuty is fully realised, according to a report published recently by a committee of the US National Academy of Sciences.

On the positive side, the report, prepared by the academy's committee on the education and employment of women in science and engineering, says that in the past decade women's share of all science doctorates has doubled, from 9% to 18%, and is still increasing in all fields of science.

Furthermore women are occupying a growing proportion of research faculty positions, particularly in the larger institutions; in the top 25 research universities, for example, women account for 35% of the growth of science faculties since 1973.

However there remain several areas of concern. One is that there continues to be a disproportionate number of women in two kinds of position: part-time instructors or lecturers which are outside the tenure stream offer little chance for productive research; and postdoctoral or research staff positions.

There are also areas in which the discrepancy between salaries for male and female research workers is giving continued cause for concern. The report points out, for example, that although the difference in postdoctoral stipends decreased from 5.7% to 4.9% between 1973 and 1975, it had increased again to 7.5% by 1977.

"On the basis of available data, it appears likely that at least a large part of the salary differences between men and women postdoctorals derives from bias. At this level no significant differences in overall ability or promise can be documented, and male and female scientists should be rewarded equally for comparable work. Systematic salary differences at this early career stage are important not only for their immediate relevance to equity, but also as a portent of future status," says the report.

Among the major conclusions of the report are that:

- rank for rank, women faculty continued to be tenured less often than men. For all ranks, 72% of the men but only 46% of the women hold tenure appointments, and this disparity is increasing
- in relation to the pools of new PhDs in the various fields, chemistry and mathematics employ far lower proportions of women faculty than other fields
- women account for all of the net growth in science faculty at the assistant professor rank for the top 50 US universities (by R & D expenditures) and for nearly half of the increase in all other institutions
- wide field of variations in rank, salary, and tenure distribution for women faculty compared to men suggest that an assumed lack of mobility of married women is at most contributory rather than a primary reason for women's evident disadvantage.

The continued plight of women in science was emphasised at recent hearings before Senator Edward Kennedy's health subcommittee by Ms Anne Briscoe of the Association for Women in Science, who claimed that despite the results of affirmative action programmes, sexist attitudes were still deep-rooted. The health subcommittee is currently discussing a "Women in Science and Technology Equal Opportunity Act". ☐

0028-0836/79/360006-01$01.00

news in brief

Silicon production costs 'reduced 90%': A new process, developed by a group of researchers at the Stanford Research Institute, California, may reduce the cost of silicon by as much as 90%, an SRI publication has claimed (*The Leading Edge,* summer 1979, p22). Thus, by 1986, 1 kg of silicon could cost as little as $5, says the article. At the moment, 1kg of silicon costs $60. Costs could be further offset by the sale of sodium flouride, a by-product of the new process, for other industrial uses. The new manufacturing method is a one-step process producing relatively pure silicon, with sodium flouride as a by-product. The necessary chemical reactions take place in one vessel and the cheapness and ease of the new process are further enhanced by the fact that the reaction is exothermic and therefore requires no outside fuel source. The main beneficiary of a new breakthrough in the manufacture of silicon would be solar energy using cheap silicon cells. However, the new process is yet to be tested on an industrial scale.

Development need not endanger the environment: Environmentally 'safe' development can be carried out by all nations according to Dr Mostafa Tolba, (right) Executive Director of the United Nations Environment Programme (UNEP). In an interview with *Siren*, UNEP's Regional Seas Programme newspaper, Dr Tolba said "appropriate environmental management should be a common practice to both poor and rich nations, and should be the meeting ground of common objectives." Developing countries should seek a solution to their environmental problems in the process of development itself. "It is not so much a question of financial resources necessary to meet environmental problems, as it is the undertaking of rational decisions based on a long-term integrated concept of development."

Dr Tolba felt that the regional approach to environmental problems was one of the most successful. UNEP's Regional Seas Programme is "one of the best of our programmes if not just the best". This programme aims to protect the enclosed seas and coastal environment where some of the highest levels of pollution are found. Compatible research will be carried out throughout these regional seas enabling a communal solution to the problem to be made. This, together with a common resolve among coastal states towards problems affecting them all, are the two most important practical achievements of UNEP's Oceans Programme according to Dr Tolba.

Aldermaston deaths: Two former workers at the UK Atomic Weapons Research Establishment, Aldermaston died from cancer last month with more than the permitted level of plutonium in their lungs. Internal organs from both mens' bodies have been sent to Windscale for tests, but it is not yet certain whether radiation caused their deaths. Kenneth Cummins, 49, had been at AWRE for 14 years and Albert Newman, 51, had worked there for 26 years. Both worked in the "active areas" of the establishment and were among the 70 men claiming damages against the Ministry of Defence for plutonium contamination (19 July, p184). Parts of Aldermaston were closed last year after 12 workers were found to have more than the permitted level of radiation in their bodies. Before these areas can be re-opened, new ventilation methods must be installed and more safety and maintenance workers must be employed in accordance with the findings of the Pochin report which examined radiological health and safety at the establishment and was published at the end of last year.

Finnish reactor delayed over safety requirements: Delays in commissioning the second set of the Loviisa nuclear power station are, it appears, due to the higher safety requirements demanded by Finland. The equipment for Loviisa, produced in the Soviet Union, includes a number of modifications not considered necessary for Soviet home consumption. These include a containment vessel and a shield to prevent internal corrosion of the reactor's pressure chamber.

In mid-June, the Finnish power authority Imatran Voima announced that the loading of the second set had been postponed, "since talks between Finnish and Soviet specialists on the removal of the sheild had not yet been concluded." It was not clear at that stage why an anti-corrosion shield should need to be removed at all, although the Finnish media stressed that Imatram Voima "wished to observe strict safety standards" and "in case the chamber needs to be repaired" were ready to postpone the loading till August "or ever later".

The most recent news from Imatran Voima reveals that the authority had applied to charge the set in June, but the Radiation Protection Institute had delayed permission, after cracks had been found in the "inner anti-corrosion coating of the vessel" (presumably the "sheild" referred to in earlier statements). These cracks, it was alleged, were due to slag "inclusions". The Soviet suppliers have offered an explanation of these faults.

Air pollution complaints increase: The number of complaints about air pollution made against industrial works in the UK increased in 1977 despite an overall reduction in air pollution, according to a Health and Safety Executive report published recently. Mineral works were the worst offenders accounting for 97 of the complaints. The Chief Inspector of HM Alkali and Clean Air Inspectorate, Frank Ireland, said "We receive far more complaints today about far less pollution compared with conditions even 10 years ago when the situation was much worse." More inspections, stricter standards and greater public awareness probably accounted for this increase.

There was also a slower rate of implementation than expected of new emission standards set by the Alkali and Clean Air Inspectorate in 1977 due to the economic depression. Some old plants were kept active to keep staff in employment, particularly in the iron and steel industries, and other industries were allowed longer to implement the new standards so that they could spend scarce resources on creating or maintaining existing jobs. Existing standards, however, were never relaxed and in many cases emissions were considerably better than requirements. *Health and Safety: Industrial Air Pollution* 1977, HMSO (London) £3.

Pioneer 11 discovers new ring of Saturn: The Pioneer 11 spacecraft, which successfully flew past Saturn last Saturday, has discovered a fifth ring, the "F" ring, lying outside those already known and circling the planet. Attempts to find evidence of a broader, more diffuse "E" ring have given only ambiguous results so far. The gap between the "A" and "F" rings has now been labelled the Pioneer Gap. Photographs returned from the space craft also indicate the presence of a dark blue jet stream with greenish tinges near Saturn's north polar region and of a possible new satellite. The satellite which appears faintly in photographs has yet to be positively identified: it may be a newly discovered moon or possibly some known satellite appearing unexpectedly.

Short wave radio fools Fire Brigade: A short wave radio in the Israeli Embassy in London is now thought to be the cause of the radiation detected recently at Kensington Fire Station (30 August, page 715). The National Radiological Protection Board called in by the London Fire Brigade found no unusual levels of radiation and thought interference from radio waves may have caused the fire brigade equipment to register radioactivity.

0028-0836/79/360007-01$01.00

Students meet before the conference: social values are not being taught with technology

Scientists and clergy debate global problems

Scientists and theologians from the First and Third Worlds met recently to discuss the social impact of western science and technology. Much of the debate was heated as **Dr A R Peacocke**, of Clare College, Cambridge University, reports.

AN unprecedented world conference on 'Faith, science and the future', organised by the World Council of Churches, was held at the Massachusetts Institute of Technology last July. It drew many threads of the WCC's previous work together and was structured around four central themes: science and faith, questions of ethics, of political economy, and plans for Christian action in relation to science and technology.

Three hundred and thirteen delegates from 56 countries attended. About half of them were scientists and technologists and half were theologians, pastors, social philosophers and politicians. More than 100 students also attended. Many church affiliations were represented and a few representatives from other religions, including Islam and Buddhism, were present. With such a mix, it is not surprised that strong feelings were expressed, especially when topics for discussion included nuclear weapons, genetic engineering, nuclear and other forms of energy and the impact of western science and technology.

Delegates from the 'Third World' were about a third of the total and rapidly constituted themselves as a pressure group. It soon became clear that they experienced 'science' primarily as technology, a technology moreover that is having an enormous and disruptive effect on their societies, with the transnational corporations cast as the principle agents of their ills. Their frustration and sense of exploitation was expressed in a resolution (not a resolution of the whole conference) in which a number of them said "we denounce the historical and current use of science and technology by industrially and technically advanced societies, to serve military and economic interests which have brought about great sufferings to the people of the Third World. This has been done in the guise of an ideology of objectivity and value-free pursuit of truth". These attitudes produced first shock and then strong opposition from western (or, more accurately, northern) scientists and others present who regarded the pursuit of knowledge of the natural world as valuable in itself and knowledge, once achieved, as ethically neutral.

This particular tension became apparent early in the conference in the contrast between the account of science, given by Professor R Hanbury Brown (astronomer from Sydney University), as "a social activity in which we seek to discover and understand the natural world" and that of Dr Rubem Alves (philosopher, Brazil) for whom "most of the explanations that science proposes about itself are not only untrue; they are dangerous", as dangerous as a wolf to Third World lambs. There was clearly a wide gulf of misunderstanding between these two typical western and Third World perspectives on science — and indeed technology should have been substituted for science in many of the discussions and even in the conference title.

It is hard to judge if this gulf was really bridged, but the western-trained scientists, technologists, economists and theologians were uneasy with the inadequate treatment, especially in the section meetings, of conceptual and critical issues such as the status of scientific models, the limitations of scientific knowledge and how scientific research projects are engendered and financed. However this was inevitable in such a mixed gathering and the concern was expressed in section recommendations which requested the WCC to initiate smaller and more professional study conferences on particular assigned problems. These kinds of recommendation are more likely to be implemented than worthy, but doomed-to-be-ineffectual, instructions to those outside the churches such as the recommendations of one section to governments on nuclear energy, and those of another to "governments, industrial companies, universities and scientists" to make scientific and technological information more accessible to all citizens.

Matching in intensity the Third World issue, was the desire of the delegates to

The conference 'wallnewspaper'

show their unambiguous support for nuclear disarmament. Confessing "the part played by science in the development of weapons of mass destruction and the failure of the churches to oppose it", the delegates were unanimous in their endorsement of a resolution (drafted by a committee chaired by Dr J Habgood, Bishop of Durham) that called for full implementation of SALT II, advocated SALT III, supported UN initiatives on disarmament and opposed the development of new nuclear weapons. However, one proposal for unilateral disarmament was overwhelmingly defeated.

The other aspect of the nuclear problem, the 'peaceful' uses of atomic energy, also led to lively controversy. Professor David Rose, of MIT, argued for the continued use of nuclear energy at least until solar energy is developed, which means in practice, for several decades. But Professor J Rossel, a Swiss physicist, argued equally strongly against its use. Not surprisingly the section report concerned with this issue was divided and at the plenary session a keen debate resulted in the passing of a resolution, by a 129-45 vote, that called for a 5-year moratorium on the construction of nuclear power plants. My impression was that this majority included a large number of votes from among the 100 student representatives who, although neither strictly delegates of their churches, nor appointed as experts, had full voting rights.

The students, from 55 nations, had met before the conference at Wellesley College, Boston, to discuss the key issues. They asserted *inter alia* that science education is not tying social values to the teaching of technology and this theme was also heard when they reported their views to the main meeting. They were again especially critical of science education which they saw as an elitist weapon used to preserve power and institutionalised values.

This raises the wider question of how representative the conference was. But, representative of whom? Certainly it voiced the profound concerns about science and technology of many active members of the Christian churches across the world, which, it must be stressed, are increasing rapidly in the Third World. It is difficult for such a conference to claim to be 'representative', but it might nevertheless aspire to leadership of opinion resulting in action. If it does, the hopes over many years of the devoted staff of the WCC (and one thinks particularly of Dr P Abrecht, the director of the Church and Society unit that was responsible) will have been justified. And, in the end, the most remarkable thing about this unique conference is not so much its plethora of resolutions and its section reports (yet to be published) but the fact that it was held at all — and in MIT. The relation of the Christian churches to modern science and technology can never be quite the same again. ☐

Can biogas provide energy for India's rural poor —

or will it benefit only richest 10-12% of rural families? **Anil Agarwal** reports on the Janata government's plans to promote the use of biogas plants

INDIA has the world's second largest bio-gas programme, surpassed only by China, and its interest in bio-gas has probably the longest history. Although the first bio-gas plants were designed in 1939, the Khadi and Village Industries Commission was able to establish only 6,000 plants by 1974. The energy crisis of that year, which sent the price of kerosene soaring above the purchasing power of rural Indians and pushed them further into the environmentally disastrous use of firewood, persuaded the government of India to promote bio-gas plants more seriously.

In the last five years, over 75,000 bio-gas plants have been set up, and during the sixth five year plan (1978-83), the government hopes to establish 500,000 plants at a total cost of Rs2175 million (Rs17.7 = £1). About a third of this sum will be provided by the KVIC and the Ministry of Agriculture as grants, the rest being raised through loans from banks. These plants will create an annual production capacity equivalent to 750 million litres of kerosene. In addition, they will generate about 12 million tonnes of organic manure, which otherwise would have been burnt as cowdung cakes for fuel.

The programme should provide jobs for over 2,000 educated unemployed people and some 40,000 skilled and semi-skilled workers.

But compared to the total bio-gas potential within the country, the current rate of utilisation is extremely slow, much slower than China, which is reported to have set up over seven million bio-gas plants in a few years. Mr T.L. Sankar, secretary of Planning Commission's working group on energy policy, estimates that India has a potential of at least 18,750,000 family size bio-gas plants and 560,000 community size plants (with daily capacities of 1.7 and 142 cubic metres of gas respectively). While the family size plants could be used by richer rural households (with 4-5 head of cattle), the community size plant could supply energy to poorer households.

If this potential were realised by 1990, bio-gas could supply India with an energy equivalent to nearly 44% of its projected electricity consumption, and reduce its projected consumption of coal by 15% and firewood by 79%. The use of firewood would be reduced to an environmentally safe level, saving forestry expenditure, and the organic manure by-product would also reduce expenditure on chemical fertilisers. Although the investment required to adopt this option would be very high, about Rs 66,000 million. Mr Sankar believes that an energy policy that places high emphasis on bio-gas plants would have the "highest cost-benefit ratio".

Earthscan

Mound of cowdung cakes: a traditional source of fuel

To promote the use of bio-gas plants, the KVIC has started a self-employment scheme under which educated unemployed persons are being given training in installation and commissioning. They are paid Rs180 for supervising the installation of each gas plant. The KVIC takes a deposit of Rs50 as security before they begin work and retains 25% of their supervision charges until the total security reaches Rs500. These 'motivators' are expected to rectify all defects in the plants they have supervised, within the first three months of commissioning, at their own cost. Through this scheme, the KVIC hopes that greater care will be taken at the time of construction and thus maintenance and breakdown problems should be reduced; it claims that this scheme has given "very good results". Over 1500 motivators have already been trained.

Problems of managing community plants

But achieving Mr Sankar's target could be very difficult. There appear to be serious socio-economic obstacles to the widespread use of bio-gas plants. Past experience has shown that small family-size plants can be used only by the richest 10-12% of rural families. The large-scale use of bio-gas plants could drive poorer families to a greater reliance on the dwindling

0028-0836/79/360009-02$01.00

supplies of firewood, as their present cowdung fuel becomes unobtainable.

Ironically, while the Chinese have unhesitatingly promoted the use of small plants, appropriate technologists in India have argued that only large community plants can benefit the Indian rural poor. But such plants require great managerial talents for their maintenance and operation, for the organisation of the collection of cowdung, valuation of the dung which would have to be purchased, and sale of the gas and manure generated. Furthermore, sociologists still have to explain what motivated those farmers who have bought bio-gas plants. While some reports say that the initiative comes largely from women, who like bio-gas as a clean fuel, other reports claim that farmers buy bio-gas plants because it provides them with organic manure for their fields, and regard the gas only as a by-product.

A conventional KVIC bio-gas plant with a mild steel gas holder

Earthscan

With financial assistance from UNICEF, two large prototype plants ($30m^3$ and $45m^3$ respectively) have been built in the village of Fatehsingh ka Purwa in Etawah district. Bio-gas from these plants will provide cooking energy for the 200 inhabitants of the village as well as energy for running threshers, chaff cutters, mini-four mills, and for pumping water and generating electricity for street and home lighting. Fatehsingh ka Purwa is mainly a village of cowherds and the ratio of cattle to man is relatively high, which makes it possible for bio-gas alone to supply energy for so many activities. The total cost of the project is Rs158,000. Each family will receive slurry from the bio-gas plants in proportion to the cowdung it supplies. Bio-gas will be supplied free for two years and thereafter the villagers are expected to contribute. Few villagers at the moment appear to be prepared to pay anything for their energy, the concept of paying for fuel being traditionally alien to them. But they should eventually pay Rs10-15 every month per family. This is only one-tenth the depreciation and interest on the project, which thus involves a considerable subsidy. The Planning, Research and Action Division (PRAD) of the State of Uttar Pradesh, which is organising the project, has hired a manager for the plants and a trust of villagers has been formed to oversee it.

Meanwhile, the Department of Science and Technology is supporting an extensive R&D programme to develop cheaper designs of bio-gas plants and identify new feedstocks which can replace or supplement cowdung. Two important designs have been developed: one by PRAD which is an improved version of a Chinese design supplied to Pakistan, and the other an indigenous design developed by the KVIC.

In the standard KVIC design, the fermentation pit (also called the digester) and the gas holder are two separate structures, the mild steel gas holder floating over the fermentation pit. This design is efficient, gas-tight and provides gas at a constant pressure, but the gas holder is susceptible to corrosion and cannot be made in the village.

In the Chinese design the fermentation pit and gas holder are combined into one brick structure, which makes it cheaper and easier to construct and maintain a bio-gas plant with a village's own resources. Although the initial versions suffered badly from gas leakages, PRAD workers now claim that their improved design is not only as efficient as the KVIC design but also half its cost. About 110 plants have been built in Uttar Pradesh and Rajasthan, and PRAD is organising training courses for constructing these plants, now called Janata (People's) Bio-gas Plants.

KVIC is meanwhile seriously evaluating its own new design in which both the digester and the gas holder are made of ferrocement. The digester is made up of a series of modular ferrocement rings which fit into each other, and the ferrocement gas holder slides into the digester. The farmer, has nothing to do but dig a suitable size pit. Some 100 such experimental plants have been set up and they are reported to be operating very satisfactorily. The ferrocement plants are about 20% cheaper than the conventional plants, but still slightly dearer than that of the Janata plants.

A hybrid design, incorporating a ferrocement gas holder with a conventional brick and mortar digester has been developed by the Structural Engineering Research Centre at Roorkee, and several voluntary groups are also working on new bio-gas plant designs. Mr J.C. Kapur of Kapur Solar Farms in New Delhi has developed a combined system of solar water heaters and bio-gas plants. The output of bio-gas plants falls drastically during the winter months, when minimum temperatures in northern India drop to near zero, and these are the months when more cooking energy is required. Solar heated water can keep the temperature in the digester at an optimum level and thus maintain the gas output. The bio-gas plant provides energy for cooking, to generate electricity for lighting, and also to take over from the solar plant for air conditioning when solar intensity is low. Kapur foresees a totally automatic interactive system.

Searching for new feedstocks

Simultaneously, several efforts are being made in various agricultural universities and research centres to find new feedstocks for bio-gas plants. The KVIC itself is experimenting with plants that use agricultural wastes (straw from wheat or rice, for example) with not more than 5% dung. Another possibility is water hyacinth, a weed that grows prolifically in various parts of India. The PRAD workers have already found that a mixture of water hyacinth and dung in the ratio of 2:3, gives a gas output increased by 40-50% and also a slurry richer in nitrogen, phosphates and potash. The KVIC is also experimenting with bio-gas plants which use urine as a feedstock: in some states the villagers are beginning to show less aversion to using human wastes in bio-gas plants.

The KVIC proposes to set up five regional bio-gas experimental centres to try out various types of bio-gas plant with a range of feedstocks in different agro-climatic, socio-economic and resource conditions. This type of research should help to identify the best designs for different regions.

But despite this vast programme, bio-gas researchers continue to be treated as second-class citizens in energy research. Work at the Gobar Gas Research Station of PRAD in Ajitmal, for instance, is treated by research workers as an interim arrangement until they find a better job. Researchers still receive low salaries and suffer from job insecurity, conditions under which no Indian nuclear researcher, for instance, would ever work. Successive Prime Ministers have stated that bio-gas is a matter of national interest, and India still needs to implement fully this good intention. □

Earth's cratering rate

from David W. Hughes

THE hysteria over Skylab's return to Earth and the unease engendered by the fact that about 600 of the 4,500 or so orbiting pieces of space hardware re-enter the atmosphere every year pales into insignificance against the shock that would follow the impact of an asteroid and the subsequent cratering event. How often are these impact craters produced? Well, a body capable of forming a crater with a diameter over 1 km hits the Earth every 1,400 years. Craters of 10 km diameter and more can be produced every 140,000 years assuming the impacting object hits land and not sea. These figures come from two reviews of the subject by R.A.F. Grieve and P.B. Robertson and Grieve and M.R. Dence of the Canadian Department of Energy, Mines and Resources and published in a recent issue of *Icarus* (**38**, 212; 230; 1979).

Terrestrial impact craters are fairly common and Fig. 1 shows their world wide distribution. Twelve of the structures shown in Fig. 1 are classified as proven meteorite craters because meteorite fragments have been found in their vicinity. The remaining 75 are 'probable' meteorite craters recognised as such because the target rocks have suffered shock metamorphic effects. It is obvious from the uneven distribution that the probability of their preservation and detection varies considerably from place to place. The majority occur in North America and Europe, areas with relatively stable geology and also with an active population of crater searchers. Erosion and geological processes progressively erase craters. For example a 20 km structure is only recognisable as a probable impact crater for a maximum of 600 million years whereas a 10 km structure usually has a lifetime of only 300 million years.

Morphologically there are simple bowl-like craters with an uplifted and overturned rim and complex craters with uplifted central peaks and slumped or depressed rims. Normally the simple craters have diameters of less than 4 km, the larger ones being complex.

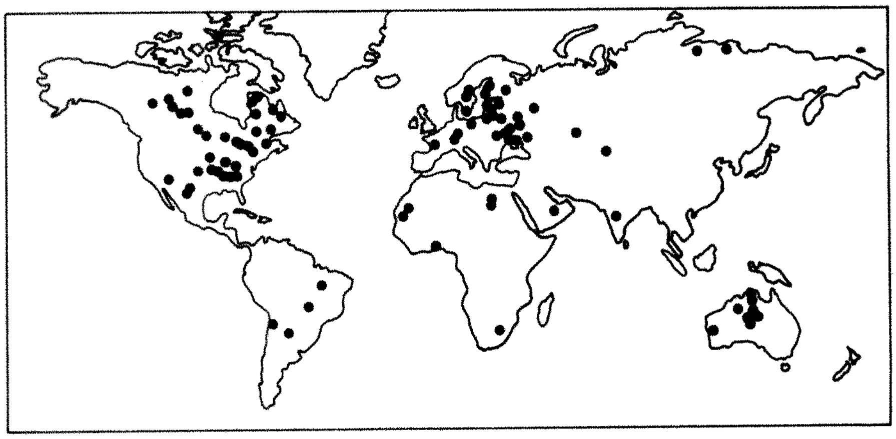

Fig. 1 The world wide distribution of impact craters (after Grieve and Robertson).

Plotting the number of craters, N, which have diameters D greater than D as a function of D it can be seen that $N \propto D^{-2}$ for D larger than 20 km. The curve departs from linearity below this size because small craters have a shorter lifetime and are less likely to be recognised. It is highly probable that the $N \propto D^{-2}$ relationship actually extends down to crater diameters of about 1 km. Martian craters obey an $N \propto D^{-2}$ law. Large lunar craters lie between $N \propto D^{-1.8}$ and $N \propto D^{-2}$. This law can also be justified by combining the mass distribution of the causative asteroids (the number of asteroids more massive than M is proportional to $M^{-0.6}$) with the relationship between the crater diameter and the kinetic energy, E, of the impacting body ($D \propto E^{0.29}$).

To calculate the cratering rate one needs ideally a large area of the Earth's landmass which has a single age of origin, preferably as old as possible, and which has undergone a minimal and uniform level of subsequent modifying geological activity. Two areas approximate to this. The first is the North American stable region that lies between the Rockies and the Appalachians and the Quachita and the Arctic. The area is 1.25×10^7 km^2 and the exposure age varies from 450 million years in the north to about 300 million years in the south. It contains 33 impact structures over 1 km in diameter, the estimated production rate being $(0.36 \pm 0.1) \times 10^{-14}$ km^{-2} yr^{-1} for craters with $D > 1$ km. The second area is the Northern European plain lying between the Scandinavian Caledonides, the Urals, the Carpathians and the Caucasus. Here there are 20 craters with $D > 1$ km. Over an area of 4.5×10^6 km^2. As with North America the exposure age varies from 450 million years in the north to 300 million years in the south resulting in a production rate of $(0.35 \pm 0.13) \times 10^{-14}$ km^{-2} yr^{-1} for craters with $D > 20$ km. Combining these two production rates gives the equation

$$\log_{10}\phi = -11.85 - 2\log_{10}D \qquad (1)$$

where ϕ is the production rate (km^{-2} yr^{-1}) of craters with diameters greater than D km. This equation is definitely valid down to diameters of 20 km and probably valid down to diameters of 1 km. The results can also be interpreted as indicating that this cratering rate has remained reasonably constant over the last 3.4×10^9 yr. Equation (1) shows that, assuming the Earth's surface was all land, a 1 km crater would be produced every 1400 yr and a 10 km crater every 140,000 yr.

We must be thankful that two-thirds of the globe is covered by water and, of the remaining land mass, the frozen wastes, jungles, deserts and mountains account for over 90% of the area. ☐

Gene mapping at the crossroads

by Mary Lindley

THE human gene map is said to be poised for rapid expansion, during the next few years, as the techniques of molecular biology and immunology take firm root in this traditional domain of geneticists and cell biologists. At a recent reunion in Edinburgh*, 150 of the aficionados agreed that they have now identified the positions of about 350 genes on the human chromosomes. Although the current rate of increase is a mere two or three genes per month, the atmosphere was full of confidence that this will accelerate rapidly, making a complete human gene map a possibility within the lifetime of some of the younger members of the gene mapping fraternity.

One of the most promising strategies involves the combination of some of the familiar tools of cytogenetics with techniques developed to investigate the fine structure of both prokaryotic and eukaryotic genes. By such methods the ß-globin gene, already believed to be on chromosome 11, has been localised more precisely by D. Housman (Massachusetts Institute of Technology) and colleagues. They used cells from hybrid clones each of which contained the Chinese hamster genome together with a section of human chromosome 11. To identify the section carrying the ß-globin gene they extracted the DNA from cells of each clone, treated it with a restriction endonuclease and separated the resulting fragments on agarose gel. The separated fragments were transferred onto nitrocellulose filters and hybridised to a radioactively labelled cloned human ß-globin DNA probe. The pattern of hybridisation revealed by autoradiography showed that the gene for human ß-globin is carried on a section of the short arm of chromosome 11. Because the gene for ß-globin is known to be linked to those for γ, δ, and ε globins, all four genes must be carried on this chromosomal region.

By a similar procedure, B.R. Migeon and colleagues (Johns Hopkins University School of Medicine, Baltimore) have used hybrid cells containing the mouse genome and a human chromosome resulting from a translocation between chromosome 11 and the X chromosome (*Proc. natn. Acad. Sci. U.S.A.* in the press). They were able to select for the presence or absence of the human chromosome because it carried a functioning gene for the enzyme hypoxanthine guanine phosphoribosyl transferase, which the mouse cells lacked. These experiments have further confirmed that the ß and δ-globin genes are carried on human chromosome 11, and show that they are not on the segment involved in the translocation.

The application of 'restriction mapping' to increasing numbers of genes now depends on the rate at which cloned probes can be producd and characterised. F.H. Ruddle (Yale University) predicted that restriction mapping will become the predominant method for mapping genes, and that the major part of the human gene map could be known by the end of this century.

Speed, convenience and scope for fine resolution should give restriction mapping an advantage over *in situ* hybridisation, which has recently revealed further information about the arrangement of the histone genes on chromosome 7. Using labelled probes of complementary RNA, prepared from cloned sea urchin genes, D.M. Steffensen (University of Illinois, Urbana) and J.J. Yunis and M.E. Chandler (University of Minnesota Medical School) have both localised the five human histone genes to the long arm of this chromosome. Their results, however, do not indicate precisely the same positions, with the latter group placing the cluster of genes nearer to the end of the long arm (Chandler *et al. Science,* in the press). The difference may be due to the difficulty of interpreting the pattern of silver grains in the final, autoradiographic stage of this procedure.

Another promising line of enquiry for the future is provided by cell surface molecules which can be recognised by biochemical and immunological techniques and correlated with the presence of particular chromosomes. A. de la Chapelle (Folkhälser Institute of Genetics, Helsinki) and colleagues have followed up previous studies which indicated an association between monosomy for chromosome 7 and defective granulocyte chemotaxis (Rutuu *et al. Nature* **265**, 146; 1977). Treating the defective monosomic granuloctyes with a radioactive label specific for glycoproteins, the Helsinki group has shown that these blood cells have much less than the normal amount of one particular glycoprotein. This suggests that a gene on chromosome 7 codes for a glycoprotein associated with chemotaxis. The same chromosome may also be involved in the expression of receptors for epidermal growth factor, according to N. Shimizu and colleagues (University of Arizona, Tucson). They have correlated the presence of this chromosome in hybrid cells with the ability to bind epidermal growth factor.

Indirect immunofluorescence, used by C.K. Eun and H.P. Klinger (Albert Einstein College of Medicine, New York), has suggested that the expression of fibronectin on cell surfaces is affected by chromosome 11. This contrasts with the suggestion of Owerbach *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **75**, 5640; 1978), who labelled surface proteins by lactoperoxidase-catalysed iodination and correlated the presence of fibronectin with chromosome 8. The disagreement arises again in the results of a similar study by M. Smith (Mount Sinai School of Medicine, New York) and colleagues who found that hybrid cells could be positive for fibronectin while lacking glutathione reductase which is associated with chromosome 8. The genetics of fibronectin it seems may be complex, and possibly may involve genes on various chromosomes. On the other hand, the discrepancy may be resolved by the application of more refined techniques.

Another promising area is represented by two reports of genes that influence the expression of oncornaviruses. Using human–mouse cell hybrids, C.E. Wright and T.B. Shows (Roswell Park Memorial Institute, Buffalo) have found a gene on human chromosome 11 that induces the expression of a mouse xenotropic oncornavirus and another on chromosome 15 involved in the induction of endogenous mouse N-tropic oncornavirus. They call these genes *BVIX* and *BVIN*, respectively, and have found that they are carried on human chromosomes homologous to mouse chromosome regions that also carry genes affecting the expression of oncornaviruses.

This suggestion of genetic conservation during evolution is just one of many examples that are emerging as gene maps are developed for different mammalian species. As well as those of mouse, rabbit and various primates, genes are now being assigned to the chromosomes of cow, sheep, pig, cat, dog and horse. As would be expected, these are providing further evidence of the conservation of the X chromosome during evolution. It is also becoming increasingly clear that other linkage groups have been strongly conserved, especially between the great apes and man. Yunis and Chandler, for example, have extended their *in situ* hybridisation study to chimpanzee, gorilla and orangutan and localised the histone genes on homologous regions of the counterparts of human chromosome 7.

Similarly J.J. Garver (State University, Leiden) and colleagues have localised the major histocompatibility complexes of chimpanzee and rhesus monkey on a chromosome homologous with human chromosome 6, which carries the HLA complex. P.A. Lalley and colleagues (Oak Ridge National Laboratory) have found that some genes on human chromosomes 1 and 6 are correspondingly linked in the baboon, indicating conservation. On the other hand, they interpret their study of the baboon counterpart of human chromosome 2, as a sign that extensive chromosomal rearrangements have occurred during the evolution of this chromosome. Many more such insights should come as the various gene maps develop. ☐

Mary Lindley is an Assistant Editor of Nature.

---

*The fifth International Workshop on Human Gene Mapping was held in Edinburgh on 9-13 July 1979. It was organised by H.J. Evans, MRC Clinical and Population Cytogenetics Unit, Edinburgh. The abstracts and committee reports will be published in *Cytogenetics and Cell Genetics.*

Hotspots and African mantle

from Peter J. Smith

EIGHT years ago Morgan (*Nature* **230**, 42; 1971) proposed the existence of hotspots, which he envisaged as manifestations at the Earth's surface of narrow plumes of hot mantle material rising from below. Ever since these supposed lithospheric penetrations have been a perpetual source of controversy. Do they exist at all? And if they do, how many are there — a few, or tens, or even hundreds? Are they really linked to deep mantle plumes? If so, are the plume positions laterally fixed in the mantle or do they (and hence the hotspots) move relative to each other? Do hotspots-plumes really account for the phenomena (Hawaiian volcanism, for example) often attributed to them? And so are linear volcanic age trends (the Hawaiian-Emperor chain, for example), hotspot traces, resulting from the motion of tectonic plates over (stationary?) plumes beneath?

Nothing like a consensus has yet emerged on any of these questions. Which makes it all the more fascinating to observe that Thiessen *et al.* (*Geology* **7**, 263; 1979) have had the temerity to superimpose this set of controversies on another uncertainty, namely, the mobility/immobility of Africa. A few years ago Minster *et al.* (*Geophys. J.* **36**, 541; 1974) concluded that for the past 10 million years Africa has been moving at the rate of about 2 cm a year. Burke and Wilson (*Nature*, **239**, 397; 1972), on the other hand, have taken the view that for the past 25 million years or so Africa has been stationary with respect to the underlying mantle; and there is much to be said for this suggestion. Palaeomagnetic data appear to rule out any major latitude changes during this period; and about 25 million years ago there was a dramatic increase in African volcanism, implying a continent that had come to rest relative to its underlying volcanic sources.

Of course, to anyone strongly committed to the existence of mantle plumes, African volcanism and African hotspots are synonymous; and to that extent Burke and his colleagues made the hotspot–immobility connection right from the start. According to this vision, the increase in African volcanism about 25 million years ago and the continued high level of volcanic activity since then simply reflect the relative ease with which mantle plumes may pierce stationary, as opposed to moving, lithosphere. Then regions of high relief/elevation without associated volcanisms are regarded as nothing less than incomplete hotspots, or highspots, resulting from the same underlying processes as the hotspots proper. Thus Africa's distinctive basin and swell topography, where the swells are seen as hotspots/highspots, becomes a natural consequence of the continent's immobility.

Those who remain unconvinced about the reality of mantle plumes, or who accept the existence of only a few of them, will find this proliferation of hotspots and quasi-hotspots outrageous. Nevertheless, it is interesting to see how Thiessen and his colleagues (who, incidentally, include Burke) combine hotspots and a stationary Africa into a consistent picture and then go on to develop the model in terms of its implication for the underlying mantle. For accepting that Africa is stationary (that is, that primary convection beneath the continent is suppressed) and that all volcanism and uplift is essentially hotspot activity, it becomes possible to speculate on the nature of the plume convection system beneath.

As Thiessen (R.) *et al.* see it, there are some 30–40 hotspots/highspots within Africa's boundaries. That is, there are some 30–40 narrow zones of upwelling mantle material; and as what comes up must go down (well, some of it), there will be downwelling of mantle material approximately midway between hotspots. For a random arrangement of hotspots, this downwelling must occur along the edges of polygons (as viewed in plan), one of which surrounds each hotspot. In other words, there will be a pattern of polygonal convection cells, as seen from above, such that any points within a particular cell will be nearer to that cell's hotspot than to any other hotspot.

The construction of such polygons in a mathematical sense was first carried out by Thiessen (A.H.) in 1911 in connection with an analysis of rainfall data, whence, as widely used in computer cartography, they have come to be known as Thiessen polygons. Of more geophysical interest, however, is the fact that Richter and Parsons (*J. geophys. Res.* **80**, 2529; 1975) were able to generate polygonal cells in laboratory convection experiments involving oil layers heated from below in cases where the upper layer was stationary. Moreover, assuming the real-Earth plume cells to extend down only to the 700 km seismic discontinuity, the experimental and African polygons had the same width-depth ratios. Thus laboratory work and observationally-based hypothesis combine nicely to produce a consistent picture.

Except that Morgan's original plumes were deep-mantle plumes, possibly originating as far down as the core–mantle interface, whereas Thiessen's plumes appear to be an upper-mantle phenomenon only. Something seems to have been lost here without acknowledgment.

Peter J. Smith is a Reader in the Department of Earth Sciences at the Open University.

Atomic spectroscopy at Orsay

from Anne Thorne

Do you prefer to believe in 'action at a distance' or in 'hidden variables in quantum mechanics'? Put another way, if quantum mechanics affords a complete description of a system, it seems to be necessary to reject the idea of local causality — that is, the idea that the causes of effects are to be found inside the relevant backward light cone. Reviewing the present status of this old dilemma at a recent conference* J.S. Bell (CERN, Geneva) described a *Gedankexperiment* in which an excited atom in a state A undergoes the radiative cascade A→B→C, emitting a photon at each stage, where A and C have zero angular momentum and the same parity. Taking the particular case that the two photons are emitted in opposite directions, then if one is linearly polarised so also must the other be, with the electric vector in the same direction. Hence information from a perfectly efficient linear polariser on one side gives information about the signal from a second perfectly efficient linear polariser on the other side. Bell described attempts to translate *Gedanken* into reality, including a variant in which the angle between the polarisers is changed while the photons are actually in flight. Although the results so far seem to favour quantum mechanics rather than 'local causality', a sceptic can still find refuge in the allowances made for detector inefficiencies, finite acceptance angles, and so on. Attempts are now being made to close these loopholes and obtain what is expected to be incontrovertible evidence in favour of quantum mechanics. Meanwhile, most of us will continue to ignore the challenge of this intriguing problem by adopting the first of the three options Bell put forward — "Don't think about it at all"!

On the same day, nicely redressing the balance between the conceptual and the practical, H. Welling (Institute of Applied Physics, Hannover) discussed important new developments in tunable lasers. The spectral region over which tunable lasers can be operated is extending rapidly into both the ultraviolet and the infrared. Welling concentrated mainly on the solid state F-centre lasers for the infrared. In particular, the F_A and F_B colour centre lasers, made by doping crystals of the heavier alkali halides with lithium and sodium respectively, cover between them nearly all the spectral region between 0.8 and 1.9 μm. The power output is in the region of 100mW, with the laser running over two or three modes (2-3 GHz), but Welling suggested that the final resolution attainable should be of the order of 100kHz.

*The 11th Conference of the European Group for Atomic Spectroscopy was held at Orsay on 10-13 July. The Organising Secretary was Professor B. Cagnac, ENS.

Anne Thorne is in the Department of Physics, Imperial College, London.

C. Cohen-Tannoudji (ENS, Paris) discussed several intriguing experiments with atoms in intense laser fields. For example, a gas can be radiatively cooled by momentum transfer between atoms and laser radiation detuned slightly from the absorption line centre, so that photons are absorbed only by atoms travelling towards them. The cooling after many such collisions is considerable: an effective temperature of as low as 0.2 K was mentioned. As another example, the energy shift of atoms in intense laser fields can be exploited for Doppler-free spectroscopy by choosing the intensity and the detuning of the laser to compensate the Doppler shift for atoms travelling in the forward direction. The Doppler shift for atoms travelling backwards is correspondingly increased resulting in a high degree of forward-backward asymmetry in the absorption line. Moreover, interpreting this same intensity shift as a change in potential, it can be seen that a high intensity gradient, as in a beam focused to a narrow waist, implies a force on the atom constraining it to the high field region. Two crossed lasers can thus provide a trap for neutral atoms, in which it should, among other things, be possible to observe a single atom over a finite period. This opens up the possibility of performing on neutral atoms the type of experiment (lifetime of metastable states, high precision hyperfine structure) that has recently been achieved with ion traps.

One particular set of experiments may be of interest to physicists outside the field of spectroscopy. These concern the measurement of the hyperfine structure of the artificial atoms muonium, μ^+e^-, and muonic helium, $\alpha\mu^-e^-$, a joint project between Heidelberg and Yale Universities, conducted at Los Alamos Scientific Laboratory. In the case of muonium, the ratio of the muon and proteon magnetic moments and the hyperfine splitting of the ground state are independently determined, and comparison of the latter with the theoretical value represents a clear test of the QED corrections. The muonic helium atom was aptly described as a "set of Dutch doll hydrogen atoms": the system electron plus pseudonucleus $\alpha\mu^-$ constitutes the outer hydrogen-like atom and the system $\mu^- + \alpha$ the inner one. ☐

International prostaglandin conference

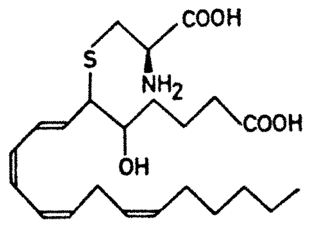
from Marie Foegh

ONE of the most exciting discoveries announced at the recent International Prostaglandin Conference* was the structure of slow-reacting substance (SRS) which has been determined by B. Samuelsson and colleagues at the Karolinska Institute, Stockholm (see Fig. 1). SRS-A (slow reacting substance of anaphylaxis), is one of the several mediators of anaphylaxis, and is of particular interest because it is synthesised *de novo* as a consequence of anaphylactic challenge and considered to be a major cause of bronchospasm during asthmatic attack. Despite much effort, the structure remained unsolved for many years.

SRS has now been identified as a novel cysteinyl derivative of arachidonic acid with a hydroxyl group at C-5 and three conjugated (Δ7, 9, 11) and one isolated (Δ14) double bond. The amino acid (cysteine) is linked as a thioether to C-6. These findings indicate the importance of the lipoxygenase pathway in its synthesis. Samuelsson introduced the term 'leukotriene' for these metabolites which are non-cyclised C_{20} carboxyl acids with one or two oxygen substitutes and conjugated double bonds. E.J. Corey (Harvard University), described routes of total synthesis to leukotriene.

SRS is a polar lipid-like substance. Arachidonic acid had previously been suggested as a precursor of SRS for various reasons and this is confirmed by the structure. The clinical implications of the newly-determined structure of SRS are apparent in immune responses of the immediate type. The non-steroidal anti-inflammatory drugs, such as aspirin, enhance SRS-A production *in vitro* by inhibiting the cyclo-oxygenase pathways of arachidonic acid metabolism. Aspirin is therefore expected to enhance SRS-A production *in vivo* and that may explain aspirin-sensitive asthma — an immediate anaphylactic reaction to aspirin and aspirin-like drugs observed in some asthmatic patients.

In clinical experience this pathological response occurs mainly in females. Falliers (*J. Allergy & clin. Immunol.* **52**, 141; 1973) has shown in a follow-up of 1,298 asthmatic patients who developed their asthma in childhood, that 1% of male patients and 4% of female patients had aspirin-sensitive asthma. These sex-differences may be related to the manner in which arachidonic acid is anabolised and catabolised. Sex differences in both platelet and vascular responses to arachidonic acid in animals were reported by P. Ramwell (Georgetown University, Washington, DC) where the male is more responsive than the female.



LEUKOTRIENE C
(SRS)

Fig. 1

J. Vane (Wellcome Research Laboratories, Beckenham, UK) presented further evidence for the hypothesis that the bleeding defect in the Greenland Eskimo is caused by an increased production of prostacyclin I_3 by vascular endothelium which inhibits platelet aggregation. An increase in production of a prostacyclin-like substance from arterial rings incubated with Δ5, 8, 11, 14, 17 eicosapentenoic acid has been demonstrated. Because of their fish diet, Greenland Eskimos have high plasma levels of eicosapentenoic acid which is the precursor of the three series of endoperoxides — prostaglandins, thromboxane and prostacyclin. In contrast to thromboxane A_2 produced from arachidonic acid, thromboxane A_3 has only a weak aggregating effect on platelets, while PGI_3 is a potent anti-aggregation substance. However, P. Needleman *et al.* (Washington University, St Louis), suggested an alternative explanation based on their observations that mammalian tissues (except for ram seminal vesicles) cyclised eicosapentenoic acid very poorly and that moreover, this acid had the same affinity as arachidonic acid for the cyclo-oxygenase enzyme. Furthermore, eicosapentenoic acid inhibited the cyclisation of arachidonate. Tissues and organs readily incorporated isotopic eicosapentenoic acid, like arachidonic acid, and it was as easily released as arachidonic acid following bradykinin stimulation. Needleman suggested that the bleeding defect in the Greenland Eskimo may be due to a decreased tendency for platelets to make thromboxane A_2 as a result of the presence of high levels of eicosapentenoic acid in plasma and platelet membrane inhibiting the cyclisation of arachidonate. Whatever the explanation, these observations raise the possibility of therapeutic intervention by diet.

Many papers dealt with the newly discovered prostacyclin. Because of its vasodilator and platelet anti-aggregating properties it has already been tested for treatment of peripheral artery diseases, and for its usefulness during haemoperfusion, haemodialysis and heart valve replacement.

In obstetrics, there have been further developments of prostaglandins of the E

---

*The International Prostaglandin Conference was held in Washington DC on 27-31 May, and organised by P. Ramwell, B. Samuelsson, and R. Paoletti. The proceedings of the Conference will be available from Raven Press, New York.

0028-0836/79/360014-02$01.00

series, where 16-phenoxytetranor-PGE$_2$ methyl-sulphonyleamide (Schering, Pfizer), 16, 16-dimethyl *trans*Δ^2PGE$_1$ methylester (ONO) and 9-deoxo-16, 16-dimethyl-9-methylene PGE$_2$ (Upjohn) have been tested for use in both early (including menstrual regulation) and late abortion. The new compounds seem to produce fewer gastro-intestinal side effects and can be given intramuscularly, vaginally or orally. M. Bygdeman (Karolinska Institute, Stockholm) reported successful abortions in 10 of 12 women in the second trimester after oral doses of 25 mg of 9-deoxy-16, 16-dimethyl-9-methylene PGE$_2$ when given every third hour; the mean abortion time was 22 h.

The conference illustrated the general applicability of prostaglandins and related compounds to all aspects of medicine. Just as prostacyclin and thromboxane synthetase inhibitors are now being developed as anti-coagulants one can look forward to major efforts to develop specific lipoxygenase inhibitors and leukotriene C antagonists for clinical use. The development of radioimmunoassays for leukotriene C should be of considerable diagnostic value in immunological diseases. □

Marie Foegh is in the Department of Gynecology and Obstetrics, Herlev Hospital, University of Copenhagen.

Yes, NGF is an enzyme

IN a recent article in the News and Views section of this Journal, P. Calissano and R. Levi-Montalcini have questioned the validity of our work on the proteolytic activity of nerve growth factor (NGF), and in particular, its ability to activate plasminogen[1]. Because their article contains misinformation, and because several of our papers on the points raised by Calissano and Levi-Montalcini were overlooked, we wish to respond as follows.

In 1977 we observed that crude homogenates of mouse submandibular glands contain multiple molecular-weight forms of NGF[2]. The largest of these, with mass 116,000, was completely purified[2] and later shown to be a specific proteolytic enzyme that can activate plasminogen[3]. It is also the predominant form of NGF which is secreted in high concentrations in mouse saliva[4]. Calissano and Levi-Montalcini state that this form of NGF "... exhibits a protease activity with an almost evanescent degree of specificity for plasminogen ...". Yet, as shown in Figs 1, 3, and 4 in reference 3 there is nothing about the proteolytic activity of this species of NGF which indicates that it is transient. Rather, the enzyme activity is real, persistent, and highly specific. NGF is indeed much less active than urokinase in activating plasminogen, and we clearly pointed that out. We also stated that plasminogen might not be the natural (physiological) substrate for NGF — only that it was susceptible to activation by this protease[3].

With regard to the possibility that the protease associated with our NGF preparations might be a nonspecific contaminant[1], Fig. 4 in reference 3 presents strong evidence that this is not the case. This figure shows that when our preparations of the 116,000 molecular-weight form of NGF are examined by gel electrophoresis, all of the protein, all of the enzyme activity, and all of the immunoassayable NGF activity migrate with identical electrophoretic mobilities — as a single component.

More recent studies have revealed that this form of NGF exhibits some unusual features which are perhaps even more interesting than its plasminogen-activating property. For example, we have now shown that NGF, as isolated from mouse salivary glands, exists as a zymogen and further, that this zymogen is converted to fully active enzyme by autocatalytic self-activation[5]. The zymogen itself is largely, if not entirely, enzymically inactive. Only after autocatalytic activation is full enzyme activity expressed[5]. This finding is probably the strongest evidence that the protease activity of NGF is specific and that it does not stem from a contaminant.

With regard to the comment of Calissano and Levi-Montalcini that the NGF activity might be "stuck" nonspecifically to other proteins present in the salivary gland, we must point out that if this is so, then it is "stuck" extremely tightly, it is "stuck" in constant ratio from preparation to preparation, and it is also "stuck" as it is naturally secreted in saliva[4]. All of this goes to the heart of an elementary problem of protein chemistry; namely, what constitutes the definition of a true molecular species. All of our results outlined above suggest that the NGF-zymogen is such a species, and we know of no published evidence which indicates otherwise.

Finally, we should like to point out that of the several (at least six) forms of NGF present in salivary gland extracts, only the 116,000 molecular weight protein is stable[3]. All of the other forms are degradation products of this single species[2]. This includes the 2.5S-NGF (molecular weight 26,000) referred to by Calissano and Levi-Montalcini[1]. In fact, 2.5S-NGF accounts for less than 10% of the total NGF found in the salivary gland, and this minor component is the one which has been used in most experiments on NGF over the past twelve years.

The proteolytic activity of the 116,000 molecular weight form of NGF is a real property of this protein, and this fact, as well as the autocatalytic activation reaction, is going to have to be taken into account before the true physiological function of NGF can be understood.

Sugars and intracellular recognition

from M. Geisow

STUDIES of the biosynthesis and structure of membrane glycoproteins have reached maturity in the past few years. The long-suspected role of sugars in cell-surface recognition processes has been established with the identification of specific receptors. However, the reason for the glycosylation of many soluble secreted proteins (plasma proteins and hormones for example) is still not at all clear. Do such conjugated sugars have analogous extracellular recognition functions? In 1965, while considering the selective export of secreted proteins, Eylar (*J. theoret. Biol.* **10**, 89) hypothesised that conjugated sugars formed part of a primitive mechanism of export from cells. This early idea was right to the extent that it predicted the existence of an export 'signal', but wrong in the sense that this signal has turned out to be a peptide rather than an oligosaccharide (see *News and Views* **272**, 308; 1978). In eukaryotic cells, newly synthesised proteins entering the lumen of the rough endoplasmic reticulum (RER) by virtue of this signal peptide must nevertheless possess further chemical or structural attributes which will determine their ultimate fate. For example, complex enzymic processing follows the biosynthesis of hormone precursors like ACTH/endorphin (Mains *et al. Proc. natn. Acad. Sci. U.S.A.* **74**, 3014; 1977). Furthermore, molecules within the ER/Golgi system, whether processed or not, need to be packaged in a different manner according to whether they are lysosomal, secreted or membrane proteins. Recent experimental work suggests the participation of conjugated carbohydrate in these intracellular recognition processes.

Melchers (*Biochemistry* **12**, 1471; 1973) found that the glycosylation inhibitor 2-deoxy-D-glucose prevented migration of

newly-synthesised IgG1 from RER to smooth ER, although it is known that this sugar acts at a number of cellular sites. Subsequent studies have taken advantage of the more specific action of tunicamycin. This drug inhibits the attachment of N-acetyl glucosamine to a lipid carrier, dolichol phosphate, blocking the so called 'core glycosylation' of glycoproteins. Hickman *et al.* (*J. biol. Chem.* **252**,4402; 1977) supported Melcher's finding when they reported that secretion of newly-synthesised IgA and IgE from plasma cells was blocked by tunicamycin. The release of λ light chains (normally not glycosylated) was unaffected and there was only minor perturbation of protein synthesis.

Although intact, non-glycosylated immunoglobulins can be detected in quantity in tunicamycin-treated cells, other glycoproteins seem to be degraded intracellularly. Schwarz *et al.* (*J. Virol.* **19**, 782; 1977) found that tunicamycin prevented the formation of mature Semliki Forest virus and fowl plague virus (FPV). At least one of the virion proteins (the sugar-free precursors of FPV haemagglutinin) was subject to proteolysis, since the specific trypsin inhibitor TLCK was needed to detect the presence of this characteristic virus protein. Analogous intracellular proteolysis of non-glycosylated fibronectin (the extracellular matrix-forming protein) was reported by Olden *et al.* (*Cell* **13**, 461; 1978).

Related, but more subtle consequences of blocking glycosylation have been described for two soluble secreted proteins. Duksin and Bornstein (*J. biol. Chem.* **252**, 955; 1977) found that non-glycosylated procollagen was secreted normally by fibroblasts, but that a step in its extracellular conversion to collagen (removal of the 3-chain carboxyl-terminal extension) was impaired. Since the non-glycosylated procollagen was processed normally by extracts from untreated fibroblasts, the impairment was probably due to the absence of cosecreted processing enzyme. Loh and Gainer (*FEBS Lett.* **96**, 269; 1978) found that the biosynthesis of ACTH/endorphin precursor in frog pituitary was unaffected by tunicamycin. However, chase experiments indicated that the subsequent proteolytic processing of this precursor was quite different in tunicamycin-treated glands. The alterations in processing particularly affected the ACTH region of the molecule, which is close to a site of sugar attachment. The processed products were recovered in poor yield, suggesting that the precursor was exposed to nonspecific fragmentation.

Not all proteins derived from ER membrane-bound ribosomes are so markedly affected by tunicamycin. Leavitt *et al.* (*J. biol. Chem.* **252**, 9018; 1977) used tunicamycin to prevent the glycosylation of vesicular stomatitis virus and Sindbis virus proteins. The non-glycosylated versions were metabolically stable, but the proteins remained 'cryptic' — they could not be detected on the host cell surface at any stage during the process of infection. Moreover, the sugar-free virion proteins were insoluble in detergent, unlike the normal glycoproteins. The authors speculated that the altered intracellular migration and physical chemical properties of the proteins stemmed from an altered conformation of the non-glycosylated polypeptides.

Semliki Forest virus proteins also remain cryptic in tunicamycin-treated cells (Garoff & Schwarz *Nature* **274**, 487; 1978). In this case gross perturbation of conformation is unlikely, since the non-glycosylated proteins are processed correctly by host cell proteases and inserted correctly into the ER membrane. Ovalbumin is one soluble secreted protein whose biosynthesis and release appears to be unaffected by tunicamycin-treated hen oviduct cells (Keller & Swank *Biophys. Biochem. Res. Commun.* **85**, 72; 1978).

An unattributable item of biochemical wisdom alleges that attachment of sugar moieties to glycoproteins confers a degree of immunity to proteases and that this occurs as much by design as by chance. In the ACTH/endorphin system already referred to, the carbohydrate on the bovine precursor molecule (Nakanishi *et al.* *Nature* **278**, 423; 1979) is very probably close to such a proteolytic cleavage site. Absence of carbohydrate sterically placed to shield susceptible peptides might well explain the degradation of certain non-glycosylated molecules. In fact, this explanation is invoked by some authors. However, an extension of this argument seems worth mentioning here, since it seems not to have previously been considered. By some device secretory material, processing enzymes and the complement of lysosomal enzymes must be segregated and separately packaged in the ER/Golgi system.

The majority, and possibly all, of the lysosomal proteins are glycoproteins. One in particular, β-glucuronidase, is known to be attached to the inner surface of the lysosomal membrane. Moreover, lysosomal proteins like β-glucuronidase in the extracellular space seem to be efficiently taken up into cells by way of a receptor-mediated event which recognises covalently-linked hexosephosphate (see *News and Views* **269**, 288; 1977).

These studies may be leading to the establishment of phosphorylhexose as an intracellular recognition signal. What happens to newly-synthesised, non-glycosylated lysosomal enzymes when secretory cells are treated with glycosylation inhibitors? Might they escape such a recognition system and enter an inappropriate compartment — a secretion granule for instance?

This line of argument leads full circle to Eylar's original hypothesis about the intracellular recognition role of conjugated sugars. Sugars do not specify export as such, but if they represent 'routing' signals within the ER/Golgi, then the diverse effects of tunicamycin might be more readily explained. Exploration of this idea will require experiments which trace normal and carbohydrate-free versions of membrane, secreted and lysosomal proteins through the cell. □

Electronic dimples explained

from P. V.E. McClintock

EARLIER this year M. Wanner and P. Leiderer reported (*Phys. Rev. Lett.* **42**, 315; 1979) that they had observed an intriguing two-dimensional crystal lattice of electron filled dimples at the interface of a phase separated ^{3}He-^{4}He mixture. This unexpected experimental result, which was obtained at the Technical University of München, has now received a fairly complete explanation from H. Ikezi of Bell Laboratories, who describes his calculations in a recent issue of the same journal (*Phys. Rev. Lett.* **42**, 1688; 1979).

The two dimensional (2-D) layer of electrons which can be floated on the free surface of liquid helium has been studied in considerable detail: it is believed to take the form of a 2-D crystal lattice of the type first proposed by Wigner (*Trans. Faraday Soc.* **34**, 678; 1938). In practice an electric field must be applied, pushing the electrons on to the surface, and depressing the centre of the liquid slightly. The individual electrons, which are highly mobile parallel to the surface, are thus prevented from spreading under their mutual Coulomb repulsion. If this electric field is made large enough (a few kV cm^{-1}), however, it is found experimentally that the surface eventually becomes unstable. The charge suddenly penetrates into the liquid, and it finally gets caught by the lower of the two electrodes providing the electric field. Studies of this instability provide information about the electron lattice and about surface waves on the liquid. Some quite detailed investigations have already been performed including, particularly, a beautiful cinematographic film of the onset of the phenomenon taken by Volodin, Khaĭkin and Edel'man (*J. exp.theor.Phys. Lett.* **26**, 543; 1977) and shown at the 15th International Conference on Low Temperature Physics at Grenoble in 1978.

Very similar considerations apply to the interfacial boundary which occurs where liquid ^{3}He floats on top of a dilute ^{3}He-^{4}He solution, but this system has only recently come to be studied in any detail. Again, the

0028-0836/79/360016-02$01.00

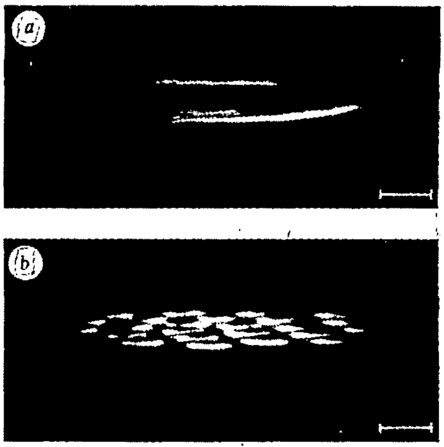

Fig. 1 Photographs of the deformation of the charged liquid ^{3}He/^{4}He interface at a temperature of 0.567 K, observed from below at an angle of 6°. *a*, For an electric field E = 1120 V cm^{-1} a single large circular indendation is produced, the elliptical bright lines indicating its rim. *b*, For E = 1160 V cm^{-1} the large indentation has spontaneously deformed into an array of much smaller circular dimples. The scale bar in each case in 1 mm.

interface can be charged with electrons and can then be depressed slightly by an electric field. Wanner and Leiderer's experimental arrangement allowed them to create ripples on the charged interface and to study the frequency-wavelength relationship (dispersion relation) using an optical technique. As anticipated theoretically they found that, for large electron densities and electric fields, the modes 'softened' — their frequencies become less for any given wavelength. This effect is a consequence of a reduction in the net restoring force for a displacement of the interface, caused by a rearrangement of electrons in the vicinity of the ripple. For very large fields, the frequency approaches zero and the whole arrangement becomes unstable, with charge breakthrough eventually occurring.

What Wanner and Leiderer found, however, was that a series of macroscopic dimples sometimes formed in fields quite close to that producing breakthrough. Their striking photographs are reproduced in Fig. 1. In (*a*) the surface is seen to be depressed in a single large diameter indentation; but, with quite a small increase in the electric field, it spontaneously breaks up into a lattice of small indentations, as shown in (*b*). The indentations were typically 1 mm apart, forming what appeared to be a hexagonal lattice (although the oblique viewing angle made exact identification of the structure rather difficult). Since each dimple was calculated to contain about 10^6 electrons, it was not at all surprising that they should try to repel each other in order to minimise their Coulomb energy and, in so doing, form a macroscopic 2-D Wigner lattice. The authors added the intriguing thought that the electrons in each dimple would presumably also be arranged in a 2-D lattice, but with a lattice constant some three orders of magnitude smaller than that of the dimple lattice. What was not entirely obvious, however, was why any dimples should be produced in the first place.

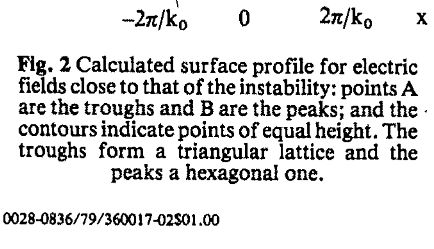

Fig. 2 Calculated surface profile for electric fields close to that of the instability: points A are the troughs and B are the peaks; and the contours indicate points of equal height. The troughs form a triangular lattice and the peaks a hexagonal one.

Ikezi has now produced the answer. He has done so by extending a theoretical approach originally proposed by L.P. Gor'kov and D.M. Chernikova (*Soviet Phys. Dokl.* **21**, 328; 1976), and has developed a theory of the surface ripples which includes nonlinear terms. The latter turn out to be of great importance near the instability. Amongst the most interesting conclusions to emerge from his calculation is that, under certain conditions, his six coupled equations lead to solutions representing a surface profile which is both stable and static. It forms the lattice shown in Fig. 2. As far as one can tell, this is in excellent agreement with the dimple structure observed in the actual experiments (Fig. 1*b*).

Ikezi points out that both shear and compressional waves should propagate through the ^{3}He-^{4}He dimple lattice; and that similar phenomena should also be observable on a free surface of superfluid ^{4}He. He predicts that the frequencies of these lattice waves should be typically a few Hertz, in which case they should not be too difficult to observe. It will be interesting to see whether he is right. □

Are supergroups the next step for electro-weak interactions?

from J.G. Taylor

IN THE past year impressive experimental confirmation has been obtained for the so-called electro-weak theory (EW) of Salam and Weinberg which unifies the electromagnetic and weak interactions under the gauge group SU(2) × U(1).

There is still a discrepancy between the Russian experiment on parity violation at Novosibirsk and an almost identical experiment conducted at Oxford [1]; the former agrees remarkably well with the predictions of the Salam–Weinberg model, in complete disagreement with the null result obtained by the latter. In spite of this there is almost universal acceptance of the electro-weak theory.

However, there are still unsatisfactory features of the model. Thus the predicted intermediate vector bosons, (IVBs) of mass about 80 GeV, have still to be seen; though they should be created around 1981 at the p$\bar{\text{p}}$ facilities now being built. There is also considerable freedom in the mechanism as to how the IVBs get their masses; even the favoured one of spontaneous symmetry breaking (SSB) has great latitude in its detailed operation. Furthermore the EW theory is not really a unified theory; the relative strengths of the interaction in the SU(2) and U(1) parts of the gauge group has to be obtained from experiment. The parameter measuring this strength, the Weinberg θ_W, has now experimentally settled down very close to the value θ_W = 30° (ref.2) as given at the CERN EPS meeting in Geneva at the end of June.

Y. Ne'eman [3]; and D. Fairlie [4] both independently noticed that the smallest group containing SU(2) × U(1) and which should require θ_W to be 30° is the supergroup SU(2|1). This latter has as generators of its group algebra the four week isopin and weak hypercharge generators of SU(2) and U(1) and in addition four anti-commuting generators. These additional generators have therefore the characteristic of fermions, and should correspond to spin half integer associated gauge fields.

Various attempts [3-6] have been made to construct a satisfactory gauge field theory of SU(2|1). None of these has been able to overcome completely the difficulty that since the symmetry group SU(2|1) is not combined with the Poincaré group symmetry of space–time the gauge fields of SU(2|1) will all be vector fields. If they have Fermi statistics, as should those which gauge the anti-commuting generators of SU(2|1), they will therefore violate the spin-statistics theorem (which only allows integer spin fields to have commutation and not anti-commutation rules). Since the

0028-0836/79/360017-02$01.00

spin-statistics theorem can be deduced from very general field-theoretical principles such a violation is not to be accepted.

Some attempts[3,5] have been made to avoid this difficulty by introducing anti-commuting supergroup parameters related to these odd generators. However the resulting dynamical theories seem to possess ghosts and other undesirable features. An alternative approach is to construct a dynamical theory which has classical fields so chosen as to be invariant only under infinitesimal variations of the group SU (2|1). The condition of infinitesimal invariance leads to a sensible physical theory and also specifies the mechanism of SSB with no further latitude. Furthermore the theory avoids the problem of wrong-statistics gauge fields by no longer allowing arbitrary gauge invariance. Only the original electro-weak symmetry group SU(2) × U(1) is full gauged; the wrong-statistics gauge fields are not required.

Such an approach does not follow the tradition of gauging all possible symmetry groups. However it cannot be dismissed lightly since it does completely unify electromagnetism and weak interactions with Weinberg angle θ_W of 30°, as well as predicting the masses of the IVBs to have the same value as the original Weinberg–Salam theory. Furthermore it predicts an associated neutral scalar (Higgs) boson to exist with mass exactly twice that of the charged IVBs. Such a prediction may also be tested at the future $p\bar{p}$ facility, though with greater difficulty than for the IVBs due to the rather weak coupling of the Higgs boson to normal matter. Another prediction which can also be tested in about 1981 is that no lepton like the electron or muon can have mass larger than about 54 GeV.

The above theory can also be extended to include strong interactions. Quarks can be fitted into the four-dimensional representation of SU (2|1) (as the leptons can into the three-dimensional one), and their colour properties as triplets under the colour gauge group SU $(3)_{\text{colour}}$ included by extending SU (2|1) to SU (5|1). Each generation of leptons and quarks (the first being e, ν_e, u, d, the second μ, ν_μ, c, s, the third τ, ν_τ, t and b) can be fitted into the 16-dimensional representation of SU (S|1), which is then reducible to the 15-dimensional representation of SU (5). This latter group has been favoured as the smallest which can contain $SU(2) \times U(1) \times SU(3)_{\text{colour}}$. SU (S|1) may thus be considered as the smallest supergroup which can properly unify the strong, electromagnetic and weak interactions.

As for SU (5) (ref. 7), SU (5|1) also has difficulties over the value of θ_W and proton stability. Latest experimental values of θ_W are nearly incompatible with the known proton lifetime in SU (5), so that a larger group may be needed. SU (S|1) has also greater latitude in the Higgs boson sector than for SU (2|1), though a neutral Higgs boson mass of twice that of the charged IVB is still predicted, along with numerous other similar particles.

Besides these predictions an interesting feature of the theory is its requirement[3,6] of extra dimensions whose only evidence is in the Higgs boson structure. Thus the theory is of Kaluza–Klein type. However the extra dimensions are required to be time-like instead of the traditional space-like ones heretofore. Each new generation of particles requires a further two time-like dimensions for its description; at present there are therefore six extra time-like dimensions alongside our present one and the associated three space-like dimensions. These extra dimensions carry only the symmetry of the theory, but are otherwise trivial. Verification in the 1980s of the predictions of the theory will give support to the existence of these extra dimensions; a very exciting possibility to look forward to.

Radiant Matter proceeds in straight Lines

The radiant matter whose impact on the glass causes an evolution of light, absolutely refuses to turn a corner. Here is a V-shaped tube (Fig.6), a pole being at each extremity. The pole at the right side (*a*) being negative, you see that the whole of the right arm is flooded with green light, but at the bottom it stops sharply and will not turn the corner to get into the left side. When I reverse the current and make the left pole negative, the green changes to the left side, always following the negative pole and leaving the positive side with scarcely any luminosity.

In the ordinary phenomena exhibited by vacuum tubes — phenomena with which we are all familiar — it is customary, in order to bring out the striking contrasts of colour, to bend the tubes into very elaborate designs. The luminosity caused by the phosphorescence of the residual gas follows all the convolutions into which skilful glass-blowers can manage to twist the glass. The negative pole being at one and the positive pole at the other, the luminous phenomena seem to depend more on the positive than on the negative at the ordinary exhaustion hitherto used to get the best phenomena of vacuum tubes. But at a very high exhaustion the phenomena noticed in ordinary vaccum tubes when the induction spark passes through them — an appearance of cloudy luminosity and of stratifications — disappear entirely. No cloud or fog whatever is seen in the body of the tube, and with such a vacuum as I am working with in these experiments, the only light observed is that from the phosphorescent surface of the glass. I have here two bulbs (Fig.7), alike in shape and positionof poles, the only difference being that one is at an exhaustion as will give the ordinary luminous phenomena — whilst the other is exhausted to about the millionth of an atmosphere. I will first connect the moderately exhausted bulb (A) with the induction-coil, and retaining the pole at one side (*a*) always negative, I will put the positive wire successively to the other poles with which the bulb is furnished. You see that as I change the position of the positive pole, the line of violet light joining the two poles changes, the electric current always choosing the shortest path between the two poles, and moving about the bulb as I alter the position of the wires.

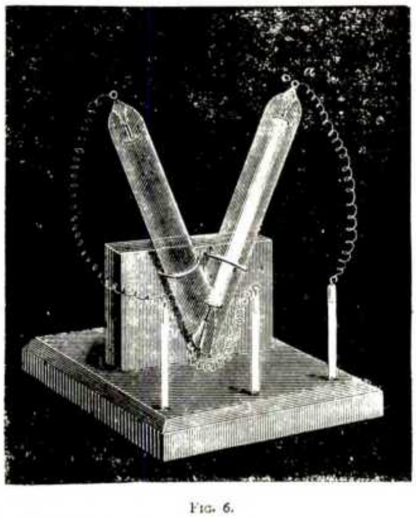

Fig. 6.

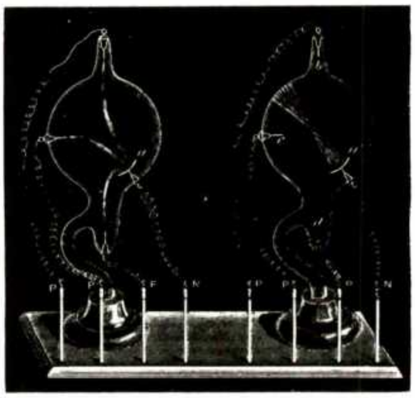

Fig. 7.

This, then, is the kind of phenomenon we get in ordinary exhaustions. I will now try the same experiment with a bulb (B) that is very highly exhausted, and as before, will make the side pole *(a)* the negative, the top pole *(b)* being positive. Notice how widely different is the appearance from that shown by the last bulb. The negative pole is in the form of a shallow cup. The molecular rays from the cup cross in the centre of the bulb, and thence diverging fall on the opposite side and produce a circular patch of green phosphorescent light. As I turn the bulb round you will be able to see the green patch on the glass. Now observe, I remove the positive wire from the top, and connect it with the side pole (*c*). The green patch from the divergent negative focus is there still. I now make the lowest pole (*d*) positive, and the green patch remains where it was at first, unchanged in position or intensity.

Radioisotope clocks in archaeology

R. E. M. Hedges
Research Laboratory for Archaeology and the History of Art, 6 Keble Road, Oxford, UK

Any absolute dating method requires some form of clock. This review considers those methods in archaeology in which the clock is the rate of disintegration of a radioactive nucleus.

UNTIL about 30 years ago, absolute dating in archaeology was restricted to the interpretation of surviving king lists and the like, while most dating was estimated from stratigraphic or cultural sequences, and their relationship to geological processes. The incorporation of radiocarbon dating has caused a sometimes dramatic[1] modification of accepted ideas, but is now regarded as an essential foundation to archaeological interpretation. Since the discovery of radiocarbon, other dating methods, with application in different circumstances, have been developed; and in the past two years new methods of detecting trace quantities of rare isotopes promise to extend the range of possibilities.

For a given isotope, its rate of disintegration, with its exponential decay law, is essentially completely independent of environmental influences. In this respect it contrasts strongly with the use, for example, of chemical clocks (such as the rate of racemisation of amino acids in degrading bone collagen, or the rate of weathering of flint). However, environment is not entirely without effect. Conditions at the 'start' of the clock must often be inferred, while, of course, there must be a connection between the 'start' and the event being dated. In fact the main challenge of dating lies in the precise articulation of these features. The difficulties of particular methods are considered below, but the example of radiocarbon illustrates the point. For radiocarbon dating, the 'start' of the clock occurs at the death of the organism which is destined to become the sample to be dated. At death, ^{14}C is no longer exchanged with its environment (that is food and atmospheric CO_2), and so the level of ^{14}C decays from its original, constant value. The original level can only be inferred from a consideration of all the processes forming and diluting ^{14}C in the relevant part of the environment, or alternatively by calibration against known-age samples. Biological fractionation and contamination must also be taken into account. With a figure for the original level, and a measurement of the present day level, the time elapsed for exponential decay is simply given by

$$t = 3.32\lambda \log_{10}\left(\frac{L_0}{L_t}\right)$$

where λ is the half life, L_0 the ^{14}C level inferred at the start, and L_t that measured. For ^{14}C the 'start' is comparatively well defined, although the death of a tree, for example, has to be more carefully formulated to apply to metabolic processes of, say, cellulose in an individual tree ring. Archaeologically, the felling of the tree may be regarded as the event to be dated, which does not necessarily correspond to the same thing at all. Also the possible re-use of a timber from an earlier structure makes the purely archaeological interpretation of a radiocarbon date that much more involved.

Archaeology is primarily concerned with the cultural development of man, but this is so closely bound up with man's biological and ecological development that the dating of the latter aspects is of equal importance. Thus while a substantial fraction of archaeological work is concerned with the past 10,000–15,000 yr, dating techniques extending to beyond 5 Myr are necessary. The accuracy of dating depends on the complexity of the information to be resolved. Rapid cultural development may require a date to within ±20 yr, which, at, say, 6,000 yr BP, corresponds to ±0.3% in the date. Beyond 30,000 yr, where radiocarbon dating is difficult to apply, sites are sparse and dates relatively few. Beyond 100,000 yr the rate of change is likely to follow the rate of environmental, such as climatic, change. The study of environmental change is not only important in its own right, but is also necessary for the proper evaluation of the dating techniques themselves. For example, the change in global ice volume can be followed from oxygen stable isotope measurements in deep sea cores[2], the sudden release of 'aged' CO_2 dissolved in retreating glaciers can then cause perturbations of the ambient ^{14}C level in the biosphere.

General approaches

The methods considered here can be grouped into three categories: (1) The decrease in concentration of a radioisotope from a presumed initial level, or the reciprocal build-up of a stable daughter product; (2) where a chain of radioactive decays exists, the degree to which the members of the chain are restored to equilibrium following some external initial perturbation; (3) the integration of some local radioactive process by the sample material. The total can then be compared with the value of the local flux, which is usually due to the presence of radioisotopes and remains approximately constant in time.

Methods (1) and (2) technically depend on the need to make accurate measurements of concentrations of radioisotopes or their daughter products, while (3) depends on exploiting a reliable integrating process. In all these cases assumptions must be made about initial conditions, and sometimes about the subsequent history. Often it is not possible to test such assumptions adequately unless a comparison, using a dating method dependent on quite unrelated assumptions, is available. The overlap between different methods has up to now been rather sporadic (mainly owing to differing time scales or materials). The recent developments in ultra-sensitive detection of specific isotopes[3], for example, ^{10}Be, ^{14}C, ^{36}Cl, have given a new impetus to the field, and the availability of new methods, with new time scales, should help considerably to bring about such cross-checking.

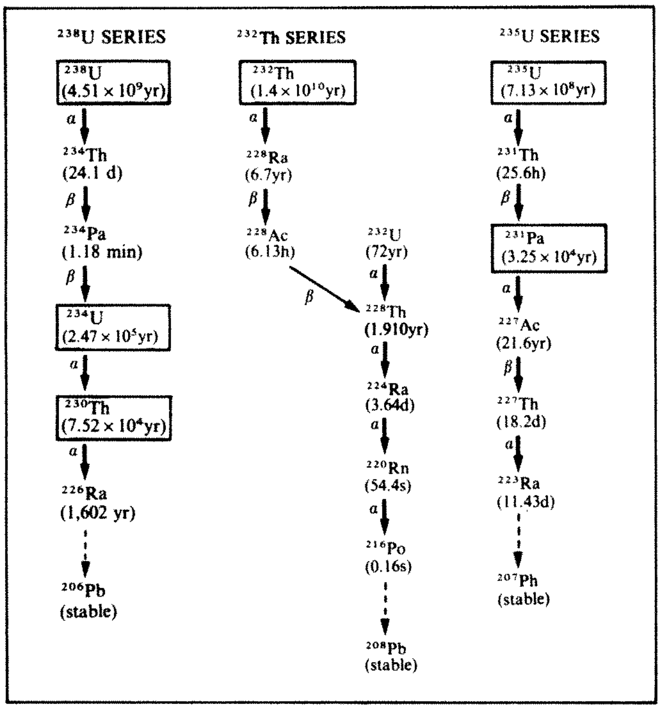

Fig. 1 Uranium and thorium decay series, indicating mode of decay and half life for the nuclides. Long-lived isotopes for dating are enclosed in boxes.

Specific techniques

For convenience we start with the abundant radioisotopes (^{40}K, Th and U), pass to the rare radioisotopes (^{14}C, ^{10}Be, ^{26}Al, ^{32}Si, ^{36}Cl, ^{41}Ca, ^{53}Mn), and finally consider radiation integration techniques (fission track dating, thermoluminescence and related techniques).

K/Ar: ^{40}K occurs with a natural abundance of 0.012% relative to ^{39}K, and a half life of 1.3×10^9yr. A small fraction decays to ^{40}Ar, so that a measurement of the accumulated ^{40}Ar, together with the quantity of parent ^{40}K (effectively constant over a few Myr) gives the age directly by integrating the exponential decay. This method is primarily applicable to volcanically formed rock such as tuff or pumice. Of course, the rock must not incorporate any additional ^{40}Ar, for example from the atmosphere, and no radiogenic ^{40}Ar must be lost from the rock. Note also that the younger the rock the less radiogenic Ar, and the greater the possibility of contamination and difficulty of measurement. Typically, rocks younger than 50,000–100,000 yr become very hard to date reliably. (The basic method and literature are well covered in ref. 4.)

More recently, the measurement of ^{40}Ar and ^{40}K has been modified in a way which can take account of material in which ^{40}Ar is lost or modified by weathering or reworking. (For reviews, see refs 5 and 6.) In this technique, ^{39}K (which is in constant ratio to ^{40}K) is measured by converting it partially to ^{39}Ar by subjecting the sample to neutron activation. The ^{39}Ar so formed is in a similar micro-environment to that of the entrapped radiogenic ^{40}Ar. On heating the activated sample in incremental steps the ratio of ^{39}Ar/^{40}Ar can be measured mass spectrometrically, and its degree of constancy indicates the integrity of the material. This is particularly important for the younger samples relevant to archaeology. Measurement of ^{36}Ar allows the proportion of atmospheric Ar contamination to be estimated, and correction for Ca-derived Ar (in the neutron activation) must also be made, especially for young samples.

The necessary assumptions in K/Ar dating are concerned with the particular samples rather than with initial conditions. The ^{39}Ar/^{40}Ar method allows the validity of these assumptions to be tested for a given case, but real confidence, especially for more recent material, comes from independent dating. Very satisfactory agreement between K/Ar and fission track dating on the age of the KBS tuff from Lake Rudolph[7,8] has been obtained. The K/Ar method has been most useful in archaeology in dating the stratigraphy for the finds of hominids. Since it is the rock that is being dated, a stratigraphic relationship must be used to provide the archaeological date.

U: There are several somewhat different methods of uranium series dating. (A general review has been given by Ku[9].) In the decay of ^{232}Th, or ^{235,238}U, a series of daughter products is encountered with a wide range of halflives. In a closed system each daughter would be in 'secular' equilibrium, but because the geochemistry of some of the longer-lived daughters differs greatly a chemical separation in the environment takes place. The degree of restoration of equilibrium, whose rate is governed by the various half lives involved, can be measured. For example, in the decay of ^{238}U, the first long half life (see Fig. 1) of a non-U member is ^{230}Th ($\lambda = 7.5 \times 10^4$ yr), and this isotope is rapidly precipitated from an aqueous environment. The parent ^{238}U will not then be in equilibrium with its daughters in natural waters. If the uranium is now co-precipitated with, say, calcium as calcite, there will be a build-up of ^{230}Th from a null concentration from ^{234}U and ^{238}U, at a rate in accordance with their half lives, until secular equilibrium is regained. Traces of ^{230}Th from detrital sources which might be incorporated can be estimated, to first order, from a measurement of the ^{232}Th present, if this is small. Often such detritus can be chemically distinguished from the calcite deposit. Provided the initial concentration of ^{230}Th is small, a measurement of the ^{230}Th component of the calcite, together with that of ^{234,238}U, allows the age of the calcite since it was formed to be computed. For suitable uranium concentrations this method is applicable to ages in the 50,000–250,000-yr range.

A major application is to carbonates, where the assumptions required are a specification of the isotopic composition during formation of the carbonate precipitate, and the maintenance of a closed system afterwards while equilibrium is being restored. In most cases, it is the isolation of the system that causes more problems. Thus corals seem to be satisfactory subjects[10] while fossil shells do not[11]. There has been increasing interest in the dating of speleothems (cave deposits), an application with a more direct contact with archaeological interests. Precipitated calcite in these environments seems to constitute a satisfactory closed system, and difficulties over the initial isotopic composition (such as ^{230}Th from dust) are not usually serious. The archaeological applications of speleothem dating by the uranium series method will be reviewed elsewhere[12]. Schwartz *et al.*[13] have previously described an application to a specific archaeological site.

Attempts have been made to extend the method to date bone[14], which strongly accumulates uranium by ion exchange during burial. However, the difficulty of taking into quantitative account the extent to which bone is an open system renders this approach hazardous, and it has not been generally pursued, despite promising results. As one of the extremely few methods that deals with the original archaeological material on a time scale beyond radiocarbon, this application deserves more attention.

^{210}Pb: Although a member of the uranium series, the 22-yr half life of ^{210}Pb puts it into a different sphere of application. Disequilibrium for ^{210}Pb arises from two causes; in terrestrial environments escape to the atmosphere of ^{222}Rn in the decay of ^{238}U brings about a precipitation of unsupported ^{210}Pb as its daughter, and the decay of the ^{210}Pb which finds its way, for example, into lake sediments enables recent stratigraphy[15] to be dated. Archaeological applications to dating using a 200-yr time scale are limited, but one use is in the determination of authenticity. Here disequilibrium is produced in a lead containing artefact during the lead extraction process, so that initially ^{210}Pb is in excess, unsupported by ^{226}Ra. This method has been applied to the dating of lead pigments[16].

The isotopes so far discussed have a terrestrial origin, with parents of very long half lives. The isotopes next to be considered have a cosmic origin[17], and are formed in minute amounts. For example, the world inventory of ^{26}Al is estimated at only 1 ton. For these isotopes especially, the use of accelerators for their detection[3] promises to bring major changes to our present knowledge, although the isotopes considered here have all been detected by conventional methods with one exception (^{41}Ca). A brief survey of the new possibilities has been made by Arnold[18].

^{14}C: A comprehensive review of ^{14}C dating in archaeology has been given by Aitken[19]; the subject is too vast to attempt here, but it is worh indicating the similarities and differences between ^{14}C and the less-studied isotopes.

First, ^{14}C has some extremely fortunate properties which make it eminently suitable for archaeological dating. These are: a convenient half life (5,730 yr); the ability to equilibrate with the biosphere and so have a direct interaction with man's activities; and a uniform global distribution arising from its equilibration with dissolved oceanic CO_2. Furthermore, ^{14}C is present in sufficient abundance to provide adequate samples for its measurement ($^{14}C/^{12}C = 10^{-12}$ for recent material). ^{14}C is formed by cosmic rays through the (n, p) reaction on atmospheric ^{14}N, unlike the other isotopes which are predominantly derived from spallation processes. Again unlike the other isotopes (except ^{36}Cl), it is oxidized to a stable gas molecule, CO_2, which equilibrates with the major carbon reservoir of the Earth, the oceans. The level of ^{14}C in the atmosphere, which is responsible for the level in vegetation and thence in such archaeological materials as charcoal or bone, is maintained by a great number of interrelated processes[20]. The formation rate[21,17] depends strongly on the degree of shielding of galactic cosmic rays both by the Earth's magnetic field and by that of the Sun, both of which vary with time. Because there is no energy threshold for ^{14}C formation (unlike the other isotopes) the formation rate is also more sensitive to bursts of low-energy protons during solar flares. Equilibration with the ocean (or rather the surface mixing layers) has a fractionating effect, which is temperature dependent, and is therefore influenced by global and local climate. Mixing rates with the deep ocean, which is the main reservoir, are not short compared with the half life, and provide a further source of variation. The imprisonment of dissolved CO_2 in glaciers and ice caps has already been mentioned. The well known calibration of ^{14}C levels[19,22–24], based on an independent dendrochronology of samples, shows that for the past 7,000 yr the atmospheric level has varied by <10%. However, the variation actually found shows a very interesting relationship to known changes in the geomagnetic field[25], as well as shorter-term changes related to solar activity[26]. From the immediate archaeological viewpoint these world-wide variations[27], enable calendar dates to be derived from the measured residual ^{14}C level in a sample. We still need to take account of fractionation in the metabolic processes which incorporate the ^{14}C in the sample, but this can be done through a measurement of the parallel fractionation in the stable isotope $^{13}C/^{12}C$ ratio for the same sample. In some cases a rapid fluctuation in atmospheric ^{14}C level can lead to ambiguous calendar dates, but this is fortunately rare for the period studied. However, it does increase the range of error for a calibrated date. Where a sequence of accurate ^{14}C measurements can be made, as in individual growth rings, a very accurate calendar date may be possible by fitting to the appropriate deviation on the calibration curve ('wiggle matching'). For much earlier times, calibration must await an independent, high resolution, alternative dating. There is some indication that ^{14}C atmospheric levels have remained fairly constant for the past 30,000 yr[28], and some evidence that cosmic ray production rates have not varied greatly (less than a factor of 10% on average over the past 10 Myr[17,29]).

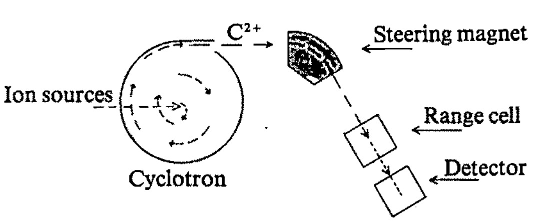

Fig. 2 High-energy mass spectrometry for the detection of ^{14}C using a cyclotron. The ion source may be external or internal. N^{2+} is removed at the range cell. The detector measures the energy loss rate and total energy of each particle.

Measurement of ^{14}C residual levels has hitherto been made by counting the ^{14}C β-decay rate. This has necessitated large samples (1–5 g), and has placed a limit of 40,000 yr on the age range (extended to 70,000 yr in some special cases). The accuracy of measurement now possible is ±0.2% corresponding to ±16 yr. The typical archaeological sample is rarely dated to this accuracy, however, mainly because of the degree of chemical and mechanical contamination while buried.

An alternative method of measuring ^{14}C, by counting ions rather than nuclear distintengrations, enables smaller samples to be used (by a factor of 10^4). This allows new types of material to be dated; for example, iron artefacts containing dissolved carbon, or single bones containing residual collagen, or individual surviving seeds. Samples can be stringently tested and purified to avoid chemical contamination. Also there is much greater choice available in selecting samples. The very low backgrounds in measurements by ion counting technique enables very much older material, perhaps to 100,000 yr, to be dated. All these methods (Figs 2 and 3) are based on a form of mass spectrometry, and they accelerate the ions up to high energies (>1 MeV AMU^{-1}) in order to take advantage of the nuclear techniques of particle identification. For example, at such energies ions of the same mass, charge and energy, such as $^{14}C^{4+}$ and $^{14}N^{4+}$, interact differently with matter, losing energy at different rates, and they can therefore be distinguished. Both cyclotrons[30] and tandem electrostatic accelerators[31–33] have been used (see also ref. 3). The Cyclotron provides a mass spectrometer with a very high rejection ratio; the tandem electrostatic accelerator, by virtue of the charge changing interaction at the stripper, can qualitatively reject many particles (for example, molecular ions). The relative merits of each approach depend on many technical issues, including the particular isotope studied, but those groups actively involved in the development of ^{14}C dating are all using tandem accelerators. It remains to be seen whether the mass spectrometric method can equal the radioactive counter method in accuracy.

^{10}Be: The ^{10}Be isotope, as with ^{26}Al and ^{32}Si, is produced in the upper atmosphere and circulates as an aerosol. Mixing with the troposphere is unevenly distributed throughout the Earth, and the isotope is rapidly precipitated from the troposphere in rain. There is a strong latitudinal variation, reflecting precipitation and mixing rates, and also, at least for ^{32}Si, a seasonal variation. The quantities of these isotopes reaching the Earth should respond much more sensitively to rapid fluctuations in the cosmic ray flux, since their residence time in the atmosphere is so much less than ^{14}C (which equilibrates with the ocean surface). ^{10}Be has been measured in cores from Antarctic ice[34,35] and also in deep sea sediments[36].

^{10}Be has a half life of 1.5 Myr, and so would provide a suitable time scale to date Pliocence–Pleistocene events. From the strictly archaeological point of view there seems little prospect of any direct connection between an archaeologically significant event and the 'start' of the Be clock, except through the dating of sediments. However, the accurate calibration of sediment cores allows one to calibrate other important stratigraphic measurements, such as changes in fauna and flora, in $^{16}O/^{18}O$ values, magnetic field reversals and changes in inclination and declination. The dating of ocean cores is still at a very early stage[38,39] and is partly hampered by the need to study the authigenic Be-containing materials of such cores. This implies careful selection of material, and so limits the sample size. Although the way in which ^{10}Be is deposited in cores is not well understood, good agreement has been obtained between magnetic reversal

~~R506~~ R407

dates and ^{10}Be ages measured on the assumption of a constant formation rate, but with a sedimentation rate adjusted to produce a consistent variation of date with depth[39].

As for ^{14}C, high-energy mass spectrometry is a suitable technique to apply to ^{10}Be measurement, thus overcoming the main difficulty of the quantity of sample required. By this technique ^{10}Be has been measured in natural samples. In particular, Raisbeck has used a cyclotron to measure ^{10}Be in Antarctic ice cores[35], and more recently, in the ocean surface water[37]. With a measured average of about 700 atoms ml^{-1}, even the atom counting method required the sampling of several cubic meters of water. With the availability of this technique the study of ^{10}Be geochemistry should now develop rapidly. The total residence time of ^{10}Be in the oceans before sedimentation, is particularly important, since this will determine the frequency response to its formation rate of the sedimentary record. For example, the data of Tanaka[39], on two cores, suggest that long-term variations (0.7 Myr time scale) are $<\pm 10\%$, and, on a shorter term (0.1 Myr) are $<\pm 40\%$.

^{26}Al: In most respects the situation for ^{26}Al resembles that for ^{10}Be. Its formation rate by spallation is lower, but, contrary to earlier views, the contribution of cosmic dust is apparently not significant[40]. Since any variation in the production of ^{26}Al should parallel that for ^{10}Be, and the two isotopes should have a closely similar geochemistry but different half lives (^{26}Al is 7.3×10^5 yr), it has been suggested that the decay of their ratio provides a time scale less dependent on cosmic ray fluctuations. As with ^{10}Be, ^{26}Al measurements are likely to be of direct importance mainly in the dating of sediment cores. Indirectly the information gained on cosmic ray fluctuations will help to calibrate radiocarbon back to earlier times.

The very low abundance of ^{26}Al (^{26}Al/^{27}Al$\sim 10^{-14}$ and below) and its long half life make determination by counting very difficult. ^{26}Al has been measured in ocean sediments by such means[41], and its measurement still poses a challenge to high-energy mass-spectrometric methods. A major problem is the interference from the isobar present in great excess, ^{26}Mg. One way to avoid this is to strip the ions fully, and Raisbeck[42] has used a linear accelerator as an injector to a cyclotron to produce and separate ^{26}Al^{13+} from ^{26}Mg^{12+}. Raisbeck's samples were artificially produced ^{26}Al in the region of ^{26}Al/Al 10^{-8}–10^{-11}.

^{32}Si: ^{32}Si has a half life estimated between 250 and 700 yr. It is therefore rather short for archaeological applications, unless it can be applied in contexts beyond the reach of radiocarbon. However, ^{32}Si profiles have been measured in siliceous sediments in the ocean[43,44] (with the aim of determining the sedimentation rate), and attempts have been made to use the isotope for dating ground waters[45]. However, ^{32}Si in the rain is diluted by the abundant Si isotope as the surface water equilibrates with the local geology. The solubility of Si is determined by many locally varying factors, so that application of the method is very restricted. It is difficult to conceive of any direct archaeological interest, although, of course, an understanding of the local hydrological history of a site might prove important. A clearer application could be to authenticity measurements. ^{32}Si has not so far been reported as being detected by high-energy mass spectrometry, but is obviously suitable for such an approach.

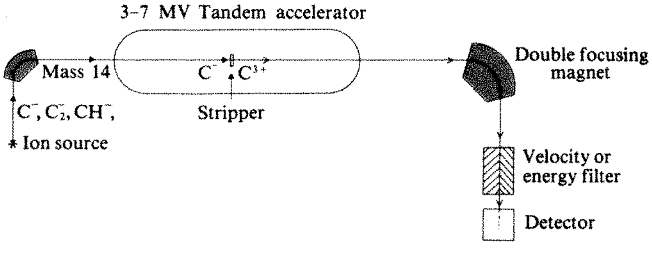

Fig. 3 High-energy mass spectrometry for the detection of ^{14}C using a tandem accelerator. Only ions of mass 14 are injected into the accelerator. Accelerated positive ions are further selected according to their magnetic rigidity and velocity or energy, before measurement of their energy loss rate and total energy in the detector.

^{36}Cl: With a half life of 0.31 Myr, ^{36}Cl would seem to have an ideal time scale for extending the archaeological dating range beyond radiocarbon. There is some resemblance to ^{14}C in that the nuclide is likely to have a fairly long residence time in the atmosphere (atmospheric sinks and sources for Cl, which although extensively studied recently, are not known quantitatively), and probably can equilibrate with the surface ocean Cl$^-$. Furthermore, a considerable proportion of ^{36}Cl may derive, not from the spallation from ^{40}Ar by cosmic rays, but from thermal neutrons by the process ^{35}Cl(n, γ)^{36}Cl. This could be important in Cl-bearing terrestrial rocks and at the ocean surface. Very few measurements of terrestrial ^{36}Cl have been made (although measurements in meteorites are relatively plentiful), and these are made more difficult by the lack of positive identification of ^{36}Cl from the weak β radiation counted. One such early study of ^{36}Cl in rain[46] concluded that considerable enhancement from bomb-testing had taken place. Note that this work required a 2,000 gallon sample. The Rochester/Toronto group[47], with a tandem accelerator, used about 1–5 l of water and achieved a background sensitivity of ^{36}C/Cl $\sim 10^{-15}$. As with ^{26}Al and ^{41}Ca, the presence of an isobar (^{36}S) in great excess is troublesome. In this case chemical methods (zone-refining) were used to reduce the ^{36}S level to a value where, although the dominant detected ion was at mass 36, the detector was no longer overwhelmed by the ^{36}S count rate.

Two types of application seem possible for ^{36}Cl (ref. 48). The concentration of ^{36}Cl in terrestrial rocks remains to be positively determined, but since 1—2 m of rock would be a sufficient shield to prevent ^{36}Cl build-up it might prove possible to date the time of exposure of a new face, or possibly the burial of formerly exposed material. For example, events such as the emplacement of a glacial erratic, burial by volcanic action, or the occurrence of earthquakes could be studied. This would be a significant extension to the range of terrestrial dating methods for the Pleistocene period. The second type of application is concerned with the solution geochemistry of Cl. The environmental measurements made so far have all concentrated on this aspect, but for quantitative work the major question is to determine the extent to which the groundwater system is closed. Again, as with ^{32}Si, an understanding of the former hydrological status of a region may be vital information in reconstructing its ecology. As for dating associated material, contemporary sediments may possibly incorporate sufficient Cl for dating purposes. Thus argillaceous sediments, possibly speleothems, as well as evaporites might be useful.

^{41}Ca: The isotope ^{41}Ca, with a half life of 0.13 Myr, is more probably formed by ^{40}Ca(n, γ)^{41}Ca than as spallation products in the upper atmosphere. Thus in many ways it resembles ^{36}Cl, and it has been suggested that it could be useful for dating in the same way[49]. Ca participates much more actively in geochemical cycles, and especially as a major constituent of bone, and so would seem to be richer in possibilities.

The equilibrium ratio ^{41}Ca/^{40}Ca at the Earth's surface would be expected to be in the region of 10^{-14}, which should not be beyond the range of high-energy mass spectrometry. However, the presence of ^{41}K as an isobar is an obvious problem. It could be possibly differentiated from ^{41}Ca by total stripping, as with ^{26}Al, but the energy and therefore the accelerator to accomplish this would have to be very large (>300 MeV), although not beyond present-day possibility.

As with ^{36}Cl, ^{41}Ca could be used to date the exposure of formerly buried rock. (The shielding depth is estimated to be about a metre.) Alternatively, the date of burial of surface material whose ^{41}Ca was in equilibrium could be studied. Since Ca is relatively abundant, its range of applications could be quite large. Again as with Cl, the dating of material formed from Ca-bearing solutions can also be attempted. The usefulness of this method will depend on how reliably the ^{41}Ca content of the relevant hydrological system can be estimated; for example, the expected level of ^{41}Ca deposited in growing bone. If a bone of known initial ^{41}Ca was rapidly buried, or left in a cave, the subsequent decay of ^{41}Ca (provided there was no further exchange) would enable it to be dated just like radiocarbon. The same would apply to the formation of speleothems, with the advantage of a cross check. Such possibilities make ^{41}Ca one of the most interesting cosmogenic radionuclides for archaeological dating, but also technically the hardest to detect. Also, as there is no equilibration with large reservoirs, local fluctuations of ^{41}Ca concentrations may render it too inaccurate to be useful.

Heavier isotopes

Heavier isotopes are also suitable candidates for detection by high-energy mass spectrometry. Their presence on Earth is due to factors such as the infall of cosmic dust, and micro-meteorites. One application, conceivably relevant to archaeology, dated the age of a meteorite fall at 4 Myr from measurements of its ^{53}Mn and ^{36}Cl concentrations[50]. Ocean sediments and volcanic deposits are likely to be the main subjects for study for ^{53}Mn (half-life 3.7 Myr) and ^{129}I (half life 17 Myr). Other isotopes could be included[18] and when their quantitative study is possible, further and unexpected details about the history of the Earth will emerge. For example, knowledge of the overall cosmic ray flux could help with ideas on the extinction of the dinosaurs.

Fission track dating

In this method[51] the accumulation of the fission events of ^{238}U in a material is measured, in contrast to the measurement of the quantity of atoms undergoing radioactive transformations. Many materials, especially glass (for example, obsidian, man made), minerals such as zircons or micas, and rock types such as tuff, basalt or granite, reveal, after etching, microscopic tracks recording each fission event. The density of tracks within a sample increases linearly with time (for archaeological time scales) and the absolute age since the formation of the sample can be derived simply by exposure to a calibrated neutron flux.

The practical application of the method depends on the availability of suitable materials, which must contain sufficient uranium, or be of great enough age, to have accumulated a measurable density of tracks. The dating of the KBS tuff already mentioned is a good example[8]. Other examples are to be found in the review by Fleischer[52], although such geological applications are not as common as might be expected. As a rule, man-made materials are too recent or contain too little uranium for useful dating by this method, although occasional exceptions, such as a high uranium glaze, are known. A more useful application is where geological tracks in a natural material have been annealed by heat, perhaps accidentally, in a man-made fire, and the time of resetting of the 'clock' can then be measured. For example, an obsidian spearhead approximately 5,000 yr old was 'dated' in this way[53].

Thermoluminescence

The well-established use of thermoluminescent dosimeters serves to demonstrate the ability of some materials to integrate α, β and γ doses as low as those occurring in the natural radiation environment of, for example, pottery. Several components of pottery itself have been found to give sufficient thermoluminescence (TL) when integrated over archaeological times. The firing of a pot erases the accumulated geological TL, and subsequent build-up of TL proceeds approximately linearly with time during the burial of a sherd, until the TL is 'read-out' by the rapid heating of a small sample (a few milligrammes, see Fig. 4). Electrons, produced as a result of the radiation dose, remain trapped in the lattice until a level of thermal energy is reached enabling them to recombine. Light produced by recombination near a luminescent centre is detected with a photomultiplier. The sensitivity of the particular sample to radiation is separately calibrated with a laboratory source. (The application to archaeological dating is reviewed in ref. 54.)

Various difficulties beset the technique and limit the accuracy that can be expected from it. Since TL relates directly to archaeological material it is potentially of great value, and much effort has gone into reducing the complications. First, the radiation dose is hard to assess accurately; the dose from surrounding burial soil is a significant contribution, and although measurable on site, is affected by burial soil moisture; the water content of the potsherd must be considered; and the likelihood of disequilibrium in the uranium and thorium daughters present in the fired clay is another difficulty. Some materials, such as felspars, are known to lose their TL with time, although this does not seem to be true of the most commonly used mineral, quartz. However, the TL response of quartz is somewhat dependent on its thermal and chemical history. It is possible to select for different components of the α, β and γ doses (which arise from internal ^{40}K, U and Th, and daughters, as well as environmental and cosmic radiation) by using grains of differing sizes[55,56]. Zircons have been used because only the internal U content need be considered[57]. Unfortunately, there is a spatial mismatch between the zoning of U concentration and the regions of high TL sensitivity in a given grain and this makes the analysis exceedingly difficult.

However, despite these drawbacks, the TL method has provided several pottery dates to an accuracy of ±5% and many at ±10%, and is useful where radiocarbon dates cannot be obtained. For old (pre-ceramic) sites, where radiocarbon dates suffer from potential contamination by modern ^{14}C, TL has been applied to such materials as hearths[58] and burnt flint[59]. There are further prospects that the method can be developed for dating lava flows, ocean sediments, and speleothems.

Summary and prospects

Clearly the ^{14}C isotope will continue to be the mainstay of archaeological dating, and is strengthened by its new-found ability to date samples up to 10,000 times smaller than before. The direct interaction of the ^{14}C cycle with archaeological events is an advantage hardly shared by the other cosmogenic nuclides. Furthermore, for dating into the distant past where much less can be assumed about environmental conditions, errors in estimates for initial values of the radionuclide at the 'start' of the clock will be more serious than is usual from radiocarbon dating. For radiocarbon an error of a factor of 2 corresponds to one half life (5,730 yr), not a disastrous error for a time scale at 30,000–100,000 yr. However, for, say ^{41}Ca, a factor of 2 variation in initial level would produce an error of 130,000 yr; the absolute error is greater for other isotopes.

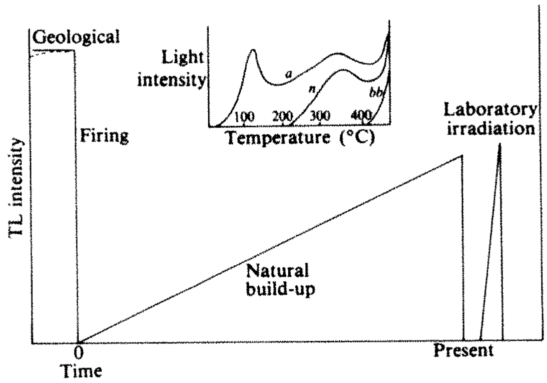

Fig. 4 The build-up of the thermoluminescent signal in pottery with time. Firing the clay erases the geological TL. In the laboratory the accumulated natural TL is measured, and then the TL from an artificial irradiation. Inset shows Glow-curves from a sample: *a*, from artificial irradiation; *n*, from naturally acquired TL over a long period of time; *bb*, the component of light due to black body radiation.

Apart from thermoluminescence, and the possible dating of bone from ^{41}Ca or by U series disequilibrium, most of the dating methods described provide direct dating only through the dating of stratigraphically associated material. This can sometimes be directly impressed by archaeological events as demonstrated by the record of hominid footprints in the Laetolil tuff of Tanzania[60], material which has now been dated by K/Ar. Note how much archaeological interpretation particularly for the Pleistocene gains from greater knowledge of the environmental changes that have taken place. Clearly ^{10}Be, ^{26}Al, ^{36}Cl in particular can provide a great deal of such information—not necessarily by dating, but by including calibration of the variation in cosmic ray flux, mixing rates for different epochs between the various terrestrial reservoirs, calibration of geomagnetic changes, and the determination of former local hydrological patterns. Much of this is related to a clearer understanding of the climatic system. Such an ambitious and complex programme is only possible if based on a great quantity of environmental measurements, which has now become possible with the application of high-energy mass spectrometry. The next decade will bring greatly increased quantitative knowledge to the study of climate and its relationship to the development of man.

There is, nevertheless, a gap in archaeological dating beyond the time scale of radiocarbon. At this age man has left few traces; bone, worked tools, fires and disturbed levels are all that we have to 'start' the radioisotope clock.

Interstellar scintillation and compact sources in supernova remnants

J. M. Cordes & J. M. Dickey

The Five College Radio-Astronomy-Observatory, University of Massachusetts, Amherst, Massachusetts 01003

Interstellar scintillation was detected from a source in or near the supernova remnant G78.1+1.8, implying an angular size $\leqslant 10^{-6}$ arc s, a brightness temperature $>10^{18}$ K, and a distance of ~3 kpc. The source does not seem to be a pulsar and is therefore the first source other than a pulsar to show interstellar scintillation. We place limits on the scintillating flux for 15 other galactic and extragalactic objects.

ALTHOUGH it is clear that some supernovae produce pulsars, it is by no means certain that all supernovae leave behind compact stellar objects nor that all such objects are pulsars. Recently[1] a new class of objects associated with supernova remnants (SNRs) has been proposed, these are radio sources with spectra markedly different from those of pulsars. While the prime candidate of this new class is probably an extragalactic source[2], one member of the class, Circinus X-1, is a galactic object that is either a neutron star or a black hole[3]. The production by supernovae of compact sources that are not pulsars exacerbates

the already problematic pulsar birth rate, which is just consistent with the supernova occurrence rate if all supernovae produce pulsars[4,5]. To detect compact sources in SNRs in general and to investigate the recently proposed class of objects in particular, we searched for interstellar scintillations (ISS) produced by electron density fluctuations in the interstellar medium, which occur if the angular size of a source is in the range 10^{-7}–10^{-3} arc s. Only pulsars have been found to scintillate in the interstellar medium although high-sensitivity observations have been made of extragalactic objects[6–9]. Here we report upper limits on the scintillating flux of six extragalactic sources, five SNRs, two of the recently proposed compact sources, and a compact source in a globular cluster. In or near one of the SNRs, G78.1 + 1.8 (also known as W66 and DR4), a scintillating source was detected at 850 MHz which is galactic and does not seem to be a pulsar.

Interstellar scintillation

Scattering of radio waves in the interstellar medium (ISM) produces a stochastic diffraction pattern at the Earth that is convected through the line of sight, thus causing time variations of the signal. The accompanying frequency structure in the spectrum of a radio source has a characteristic frequency scale that is a strong function of the observing frequency. Adopting a power-law model for the electron-density irregularity spectrum in the ISM[8,10], we have

$$\Delta\nu_{ISS} = 8.8\ \text{MHz}\left(\frac{C_N^2}{6.67\times10^{-5}\ \text{m}^{-6.67}}\right)^{-1.2}\left(\frac{\nu}{850\ \text{MHz}}\right)^{4.4}\left(\frac{L}{1\ \text{kpc}}\right)^{-2.2} \qquad (1)$$

as the decorrelation bandwidth (the half-width at half maximum of the autocorrelation function of the radio spectrum) of the ISS at a radio frequency ν. Here C_N^2 is a scale factor for the electron-density spectrum, estimated from ISS of pulsars, and L is the path length through the Galaxy to the source. The level of scintillation can be quantified by the scintillation index, m_{ISS}, which is the r.m.s. of the radio spectrum divided by the mean, and is sensitive to the angular size of the source. It can be shown[8] that

$$m_{ISS}\approx\phi_c/\phi \quad \text{where} \quad m_{ISS}^2\ll1 \qquad (2)$$

where ϕ is the source size and ϕ_c is a critical angular diameter given by[8]

$$\phi_c = 0.5\times10^{-6}\ \text{arc s}\left(\frac{C_N^2}{6.67\times10^{-5}\ \text{m}^{-6.67}}\right)^{-0.6}\left(\frac{\nu}{850\ \text{MHz}}\right)^{1.2}\left(\frac{L}{1\ \text{kpc}}\right)^{-1.6} \qquad (3)$$

While equations (1) and (3) are based on the observed scintillation properties of pulsars, the ISM is inhomogeneous and, for given sources, the predicted decorrelation bandwidths are uncertain by an order of magnitude or more. The Vela pulsar, for example, has a decorrelation bandwidth a thousand times smaller than the predicted value, largely because of the enhanced level of turbulence in the Vela SNR[10].

Observations

Observations were made in July 1978 at 850 MHz and February 1979 at 410 MHz using the 91-m transit telescope of the National Radio Astronomy Observatory. The initial frequency of 850 MHz was chosen as a compromise between maximising the scintillation index and the flux of two of the more promising sources, G127.1 + 0.5 and CL4. Our source list (Table 1) also included a pulsar (PSR0329 + 54); six non-scintillating sources of various flux densities; six SNRs with associated compact sources or with 'filled' shells; the radio source near the centre of the globular cluster NGC7089 (ref. 11); and the variable radio source associated with Cyg X-3. An autocorrelation spectrometer was used to obtain 96-point spectra with 10 MHz and

1.25 MHz total bandwidths for each of two orthogonal linear polarisations. Approximately 10–30 spectra, each with integration time 1 min, were recorded at the source position, followed by an equivalent set of off-source spectra from the same declination and 10–30 min east of the on-source position. Normalised spectra were calculated from

$$S(\nu) = T_{\text{on}}[S_{\text{on}}(\nu) - S_{\text{off}}(\nu)]/S_{\text{off}}(\nu) \qquad (4)$$

where T_{on} is the on-source system temperature and S_{on} and S_{off} are the on- and off-source spectra.

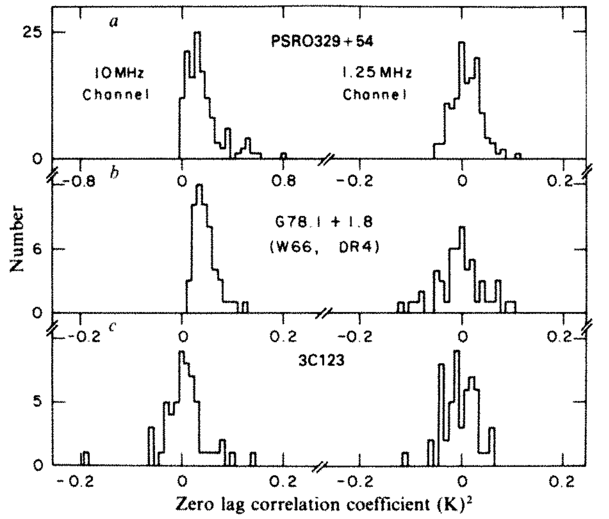

Fig. 1 Histograms of the zero-lag cross-correlation coefficient (see equation (5) with $l = 0$) for three radio sources: *a*, PSR0329+54; *b*, G78.1+1.8 (W66, DR4); *c*, 3C123. Interstellar scintillation generates frequency structure that is positively correlated between the spectra of two polarisations. Spectra with total bandwidths of 10 MHz and 1.25 MHz were analysed.

Our technique for searching for ISSs takes advantage of the fact that ISS are correlated between the two polarisations while radiometer noise and, to some extent, quasi-periodic baseline fluctuations due to standing waves are uncorrelated. Letting $S_1(k)$ and $S_2(k)$ be the sampled spectra for the two polarisations, the cross-correlation function (CCF),

$$\rho_{12}(l) = \frac{1}{N-l-1} \sum_{k=0}^{N-l-1} S_1(k)S_2(k+l),\ l = 0, 1, \ldots \qquad (5)$$

was calculated for each 1-min integration. These were summed to form an average correlation function. Histograms of the zero-lag values were formed and were extremely useful in indicating the extent to which baselines of the spectra have structure that is uncorrelated between the two polarisations. Figure 1 shows these histograms of the zero-lag points of the 1-min correlation functions for three sources. The histograms for 3C123 are symmetric about zero, as expected if radiometer noise and uncorrelated baseline fluctuations are the dominant components of the spectra. The widths of the histograms are approximately $\sigma_\rho \approx \alpha T_{\text{on}}^2/\delta\nu\tau N^{1/2}$ if only radiometer noise contributes, where τ is the integration time, N is the number of channels of bandwidth $\delta\nu$, and α is a constant of the order of unity. The histogram for the 1.25 MHz total bandwidth conforms to the radiometer noise value cf σ_ρ whereas the 10 MHz total bandwidth exceeds the radiometer noise value by a factor of 5. The excess arises from quasi-periodic baseline fluctuations with ~1 cycle every 4 MHz at 850 MHz. Such fluctuations were suppressed by subtracting a low-order least-squares polynomial from each spectrum before cross-correlating. The data presented here had a first-order polynomial subtracted. We find that the quasi-periodic baselines are generally uncorrelated between the two polarisations and that they change in amplitude and phase from one integration to the next.

ISS are evident in Fig. 1 for PSR0329+54 and G78.1+1.8 in the histograms for the 10 MHz spectra. The values of $\rho_{12}(0)$ are definitely positive for these sources, signifying that correlated structure is always present. While the presence of correlated structure is necessary to detect ISS, it is not sufficient to prove that ISS are in fact being observed. However, the shapes of the average CCFs confirm that ISS are the cause of the correlated structure. These are shown in Fig. 2. Of the 17 sources, only two, PSR0329+54 and G78.1+1.8, show correlation functions that peak at zero lag with amplitudes that are significantly larger than the magnitudes of negative excursions of the CCFs. Moreover, the shapes of the CCFs are stable from one day to the next for these sources. The quasi-periodic CCF for 3C123 peaks at a non-zero lag and attains negative values equal in magnitude to the maximum positive values as would be expected for quasi-periodic baseline structure. The CCF for the weaker calibration source 3C380 is consistent in amplitude with estimation errors expected from radiometer noise only, indicating that standing waves are not important for this source.

Note that if Faraday rotation of a linearly polarised source were significant over the total bandwidth, the resultant periodic structure would be anti-correlated between the two polarisations because the spectrum in each is proportional to $\sin^2(\beta\nu)$ and $\cos^2(\beta\nu)$, respectively, where β is related to the rotation measure. Such an effect is not apparent for any of the sources nor does the integrated linear polarisation of PSR0329+54 (which is small at 850 MHz) seem to influence the correlation functions significantly.

Table 1 shows the positions of the sources, the frequency, integration time, and system temperature; for the two sources showing ISS we list the scintillating flux density derived from

$$S_{\text{ISS}} = C[\bar{\rho}_{12}(0)]^{1/2}\, G^{-1} \qquad (6)$$

where $\bar{\rho}_{12}$ is the average correlation function, $C \approx 1.15$ is a correction factor for the flux density lost in the baseline removal process, and $G \approx 0.8\ \text{K Jy}^{-1}$ ($1\text{Jy} = 10^{-23}\ \text{erg cm}^{-2}\,\text{s}^{-1}\,\text{Hz}^{-1}$) is the system gain. A three sigma error on the scintillating flux density is

$$3\sigma_{\text{ISS}} \sim 3C\sigma_\rho^{1/2}/GM^{-1/4} \qquad (7)$$

where σ_ρ is the measured r.m.s. of the set of M zero-lag correlation coefficients for each minute of integration time. Crude estimates of the decorrelation bandwidth, $\Delta\nu_{\text{ISS}}$, were obtained by taking the lag at which the CCF crosses zero. For PSR0329+54, the two decorrelation bandwidths are consistent with values of 1.1 MHz and 43 kHz predicted by equation (1) at 850 MHz and 410 MHz, respectively,.

For the remainder of the sources, the upper limit on S_{ISS} given in Table 1 is the larger of the three sigma values given by equation (7) for the 10 MHz and 1.25 MHz total bandwidths. Although ISS were detected at 850 MHz for G78.1+1.8, they were not evident at 410 MHz above the rather high upper limit.

The scintillating source G78.1+1.8

The ISS from G78.1+1.8 cannot be easily associated with any particular source for two reasons. First, the 16 arc min telescope beamwidth at 850 MHz encompasses a complex region containing several radiosources. Second, the nature of the observations (see equation (4)) implies that ISS could have arisen from our off-source position of $\alpha(1950.0) = 20\,\text{h}\ 34\,\text{min}\ 00\,\text{s}$ and

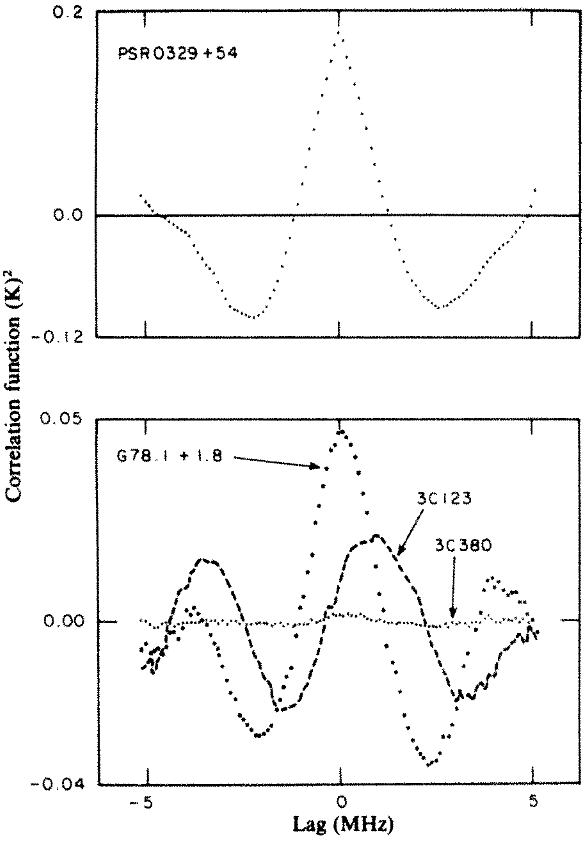

Fig. 2 Average cross-correlation functions for four sources at 850 MHz. Each lag is a multiple of the spectral resolution, 104 kHz.

$\delta(1950.0) = 40° 02' 30''$. It would not be surprising if the source were within the SNR W66, especially since the position of a γ-ray source, CG78+1, has an error box that contains W66 (ref. 12). However, the ISS may be associated with a point source[13] at $\alpha(1950.0) = 20$ h 20 min 19 s, $\delta(1950.0) = 40° 06' 09''$ which was within our beam. Although this source is variable, our observations require the flux density to have been an order of magnitude larger than the 850 MHz value expected from the measured values of 68 mJy at 1,415 MHz and 10–30 mJy at 610 MHz[13].

An obvious possibility is that the source is a pulsar. However, observations at 410 MHz using an on-line search program[14] showed no evidence of radio pulses above an average flux density of 20 mJy over a period range from 33 ms to 4 s and with a dispersion measure <120 pc cm^{-3}. The on-source and off-source positions have also been covered in two previous pulsar searches[4] that were sensitive down to at least 80 mJy. Moreover the limit on ISS at 410 MHz suggests a spectrum for the source that declines toward decreasing frequencies (that is unlike a pulsar), although the source variations may have decreased the flux density below our detection threshold during 16-min integration made at 410 MHz.

By using equations (1)–(3), we can place limits on the distance, the angular size, and the brightness temperature of the source. The similarity of the decorrelation bandwidth to that of PSR0329+54 implies a similar distance, ~2.6 kpc, although this is uncertain by at least a factor of two. Assuming this distance, we can relate the source flux density, S, to the observed scintillating flux density by

$$S = S_{\rm ISS}/m_{\rm ISS}$$

as long as $m_{\rm ISS}^2 \ll 1$. There were no unresolved sources in our beam with $S > S_{\rm max} = 1.2$ Jy[13] and therefore $\phi \leq 10^{-7} (S_{\rm max}/S_{\rm ISS})$ arc s. Consequently, the brightness temperature,

$$T_{\rm B} \equiv \lambda^2 S/2k_{\rm B}\phi^2 \geq 10^{18}\ {\rm K}$$

(where $k_{\rm B}$ is Boltzmann's constant) exceeds by six orders of magnitude the 10^{12} K maximum for incoherent electron–synchrotron radiation from a stationary source, which is limited by Compton scattering of synchrotron photons off the relativistic electrons. Although relativistic blast-wave models[15] with lorentzian factors γ can yield maximum brightness temperatures of $10^{12}\ \gamma$ K, it is probably not possible to have a source as small (linear size $\lesssim 20\%$ of a solar radius) as we have inferred without self absorption. Consequently, our results suggest that a coherent radiation mechanism is reponsible for the radiation.

We conclude that the source may be a pulsar with a period <33 ms or a pulsar of arbitrary period whose pulses are smeared out by enhanced dispersion from a region near the source. Any residual pulsation must be at a level ≤ 20 mJy or a short-period pulsar must have a flux density ≥ 0.30 mJy at 410 MHz. Either case implies an extraordinary flat spectrum as far as pulsars go. If it is not a pulsar, the source may be similar to that associated with Cir X-1, which is a binary system in which high-energy photons, produced by matter accreting on a compact object, drive a shock wave that accelerates electrons to lorentzian factors of 10^3–10^5 (ref. 3).

Compact sources in SNR

Other than G78.1+1.8, no compact sources were found in or near any of the six other supernova remnants above a flux density of ~100 mJy at 850 MHz. For G127.1+0.5 this is not surprising as the central compact source has a VLBI-determined size of 5×10^{-4} arcs s at 10.7 GHz (ref. 16). Three point sources, 4C71.01, 4C62.05, and 4C50.55, near the SNRs G119.5+10.0, G132.4+2.2, and G93.6−0.2, respectively, were not found to scintillate, signifying that such sources are indeed extragalactic or, if galactic, are too large ($\phi \gg 10^{-7}$ arc s) to scintillate at a detectable level. The SNRs with filled shells (G34.6−0.5, G69.0+2.7) do not show signs of compact sources, although our limits on these are not strong.

The point source in the globular cluster NGC7089 has a flux density of 1.3 Jy at 410 MHz and a steep spectrum ($\propto \nu^{-1.9}$) (ref. 11). Lack of ISS again argues against the source being an exotic compact object. The path length through the galaxy for this source is 1.7 kpc, assuming a disk galaxy with thickness 2 kpc, so ISS should have been detectable in the 10 MHz channel. As for Cyg X-3, the absence of ISS is not surprising because its emission seems to be consistent with an expanding incoherent synchrotron source[17].

Although our source list is too small to place meaningful constraints on the pulsar birth rate, it is clearly of interest to determine the nature of the source in or near G78.1+1.8. If it is a neutron star but not a pulsar, then the possibility exists that a significant fraction of neutron stars never manifest themselves as pulsars, therefore requiring yet more supernovae per unit time to account for the observed pulsars.

We thank S. R. Spangler, J. W. Armstrong, and J. H. Taylor for discussions and M. Damashek, J. H. Taylor, and A. Harding for help in the pulsar search. This research was supported by the NSF through grants AST 76-24610 and AST 77-20019.

Basalt magma sources during the opening of the North Atlantic

S. R. Carter, N. M. Evensen, P. J. Hamilton & R. K. O'Nions

Lamont–Doherty Geological Observatory of Columbia University, Palisades, New York 10964

The mantle that supplied basalts to the North Atlantic Tertiary province at the time of continental breakup was isotopically similar to the present-day sub-oceanic mantle. There is no evidence for undepleted source regions beneath the continent at this time.

THE determination of both $^{143}Nd/^{144}Nd$ and $^{87}Sr/^{86}Sr$ ratios in oceanic and continental basalts[1–5] has provided a stimulus to the evaluation of the timing and extent of differentiation in their mantle source regions. Volcanic rocks which erupted along mid-oceanic ridges comprise the largest proportion of terrestrial volcanics and may be expected to provide a good estimate of the isotopic characteristics of the sub-oceanic upper mantle. The relatively radiogenic Nd- and unradiogenic Sr-isotope compositions of mid-ocean ridge basalts (MORB) imply that the sub-oceanic upper mantle has been depleted in Rb relative to Sr and Nd relative to Sm.

The chemical character of the subcontinental upper mantle is a subject of considerable speculation. On the basis of thermal and seismic considerations, some authors[7,8] favour a markedly depleted subcontinental upper mantle. It is envisaged in these models that the subcontinental upper mantle has been depleted in basaltic constituents, producing a lower Fe/Mg ratio relative to the sub-oceanic mantle. Parts of the mantle which have lost a basaltic melt should not only have a lower Fe/Mg ratio but should also be depleted in the incompatible trace elements and have a lower Rb/Sr ratio and a higher Sm/Nd ratio than undepleted mantle. However, the Nd- and Sr-isotope compositions of continental basalts frequently indicate less depleted source regions than those supplying MORB. In some instances the $^{87}Sr/^{86}Sr$ ratios of continental basalts (which are often higher than the present-day bulk Earth value[2,4]) have been taken to infer the existence of ancient source regions beneath the continents that have time-integrated Rb/Sr ratios greater than that of the bulk Earth[9–11]. Several factors make it difficult to assess the extent to which continental basalts reflect the average properties of the subcontinental mantle. First, they typically sample only a small proportion of the mantle and are generated at unknown depths. Second, it is possible that they have been contaminated by the continental basement through which they have been erupted[12–14]. In some cases, such as the Tertiary basalts of North-west Scotland, basalts contaminated with continental crust may be readily distinguished from uncontaminated basalts by their isotope and trace element systematics. Third, if the subcontinental upper mantle is markedly heterogeneous, with strongly depleted and thus refractory regions interspersed with less depleted regions[8], melting events may be expected to sample the less depleted areas preferentially and provide a biased impression of the chemical state of the mantle.

The present project is aimed to obtain further information concerning the chemical characteristics and history of those portions of the subcontinental mantle which have undergone partial melting to produce continental basalt. To this end, Nd- and Sr-isotope compositions have been determined in plateau and flood basalts erupted between 50 and 70 Myr ago during the initial breakup and opening of the North Atlantic. The major occurrences of plateau lavas and intrusive centres associated with rifting of the North Atlantic are shown on a continental reconstruction in Fig. 1. The major period of rifting, volcanism and subsequent continental drift in the North Atlantic was heralded by a large-scale development of plateau lavas and intrusive complexes along the rifted margins of the proto-Atlantic Ocean. In North-west Scotland igneous activity began about 66 Myr ago and continued locally to about 50 Myr ago (refs 15, 16 and R. D. Beckinsale and R. J. Pankhurst, personal communication). The plateau lavas now forming the Faeroe Islands, and occuring in east Greenland and on either side of the Davis Strait in west Greenland and Baffin Island were erupted during the same period[17–19]. Of the samples analysed only those from the Faeroes are not definitely known to have been erupted through continental crust; Interpretation of geophysical data for the Faeroes area has been equivocal in this respect[20,21]. Altogether, the North Atlantic Tertiary volcanic province is comprised of some 2,000 km^2 of lavas which include mainly

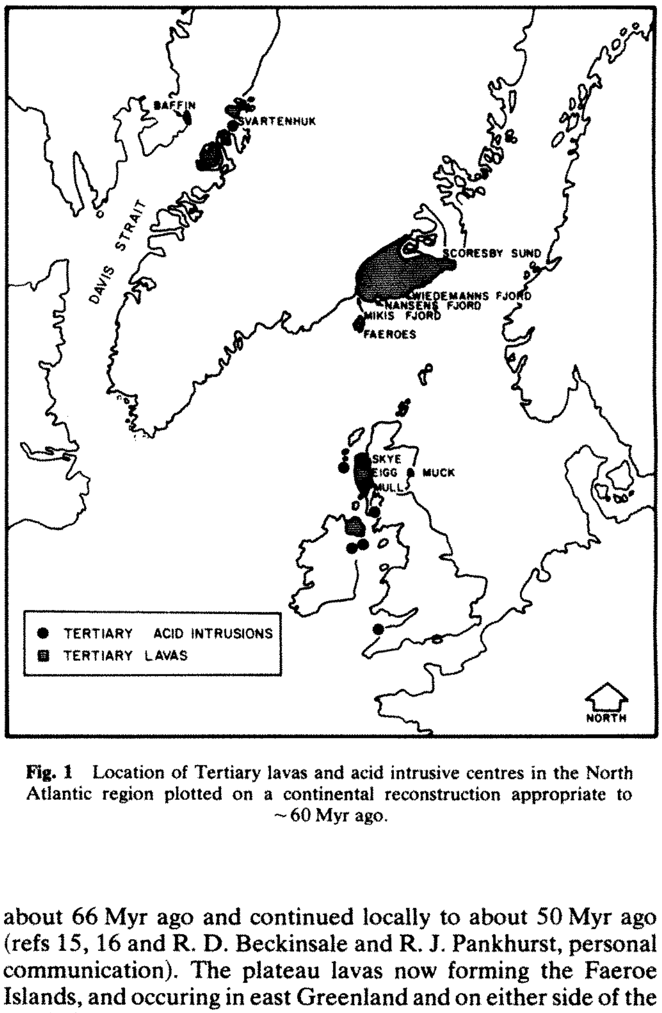

Fig. 1 Location of Tertiary lavas and acid intrusive centres in the North Atlantic region plotted on a continental reconstruction appropriate to ~60 Myr ago.

* Some of the abundance data reported from R.K.O'N. and Clarke[4].

alkali olivine basalts, but also tholeiites, hawaiites mugearites and trachytes. Central intrusive complexes occur throughout the region but are most strongly concentrated in North-west Scotland (Fig. 1) and may include periodotites, gabbros and granites.

Nd- and Sr-isotopes

$^{87}Sr/^{86}Sr$ and $^{143}Nd/^{144}Nd$ ratios together with Rb, Sr, Sm and Nd concentrations have been determined in 19 basalt samples from the Faeroe Islands, east Greenland, west Greenland (Svartenhuk) and Baffin Island (Cape Dyer). Some petrological and geochemical features of basalts from these regions have been discussed previously[22–24]. The isotope ratios presented in Table 1 are computed initial ratios assuming an age of 60 Myr; small uncertainties in the estimated time of eruption result in negligible errors in the quoted initial ratios. Within each of the provinces (Faeroes, east Greenland, Baffin and Svartenhuk) there are significant variations in the initial $^{87}Sr/^{86}Sr$ and $^{143}Nd/^{144}Nd$ ratios. $^{143}Nd/^{144}Nd$ and $^{87}Sr/^{86}Sr$ exhibit a strong negative correlation in the case of the Baffin Island and Svartenhuk samples, but only a poor one in the case of east Greenland and Faeroes samples (Fig. 2). If all the samples are considered together, however, there is a good negative correlation between these two parameters, and the range of isotope compositions is similar to that for more recent volcanics erupted in parts of the North Atlantic Ocean basin (Fig. 2)[25]. More specifically, the Nd- and Sr-isotope compositions overlap with those of recent Mid-Atlantic ridge basalts and possess a similar range to Icelandic basalts erupted over the last 16 Myr (refs 4, 24). The plateau basalts are compared with the bulk Earth Rb/Sr and Sm/Nd ratios using the parameters ΔNd and ΔSr[6] in Fig. 3, from which it is evident that they were all derived from source regions previously depleted in Rb relative to Sr and Nd relative to Sm and in this respect are similar to all basalts subsequently erupted in the North Atlantic. The Rb/Sr ratios of these basalts range from 0.004 to 0.099, both less and greater than the model bulk Earth value of 0.03 (refs 2, 4), and Sm/Nd ratios range from 0.2555 to 0.342, again less and greater than the bulk Earth value of 0.31 (refs 1, 4). This feature of variable Rb/Sr and Sm/Nd ratios is not uncommon amongst basalts erupted in the ocean basins. There are no clear general correlations between the Sm/Nd, Rb/Sr, $^{143}Nd/^{144}Nd$ and $^{87}Sr/^{86}Sr$ ratios in these basalts.

Localisation of crustal contamination

In addition to the analyses presented here, Nd- and Sr-isotope data are also available for Tertiary basalts from North-west Scotland (Skye, Mull, Eigg and Muck)[14]. The major contrast between the North-west Scotalnd basalts and those from the other locations in the North Atlantic province is the clear divergence of the $^{143}Nd/^{144}Nd$ and $^{87}Sr/^{86}Sr$ ratios of some basalts from the trend defined by the results presented here and for other recent North Atlantic basalts (Fig. 4). These divergences have previously been attributed to contamination of the basalts by the 2.9-Gyr-old Lewisian basement gneisses through which they were erupted. In some instances this contamination involved Lewisian granulite facies material with negative ΔNd values in the range −30% to −40% and ΔSr values between −20% and −40%. Elsewhere, Lewisian amphibolite facies material with similar ΔNd values, but with positive ΔSr values of more than 100%, seems to have been the contaminant.

So far, there is no evidence for basalt contamination by Precambrian basement elsewhere in the Tertiary North Atlantic.

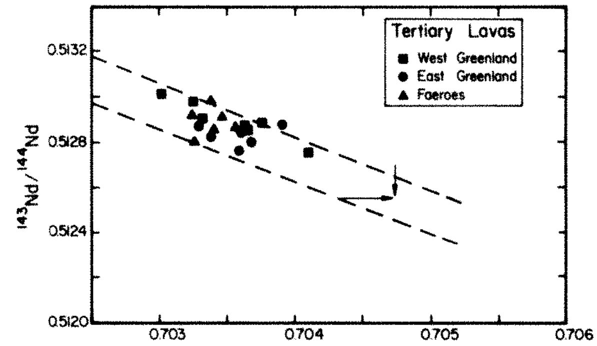

Fig. 2 Comparison of $^{143}Nd/^{144}Nd$ and $^{87}Sr^{86}Sr$ ratios in North Atlantic volcanics (Table 1) recalculated for their time of eruption 60 Myr ago and compared with the bulk Earth $^{143}Nd/^{144}Nd$ and $^{87}Sr/^{86}Sr$ ratios (indicated by arrows) and inferred bounds of contemporary Atlantic basalt source regions at that time.

It is evident that contamination is a common but localised feature of the North-west Scotland basalts and correlates with the concentration of Tertiary acid intrusive centres in this region (Fig. 1). The Pb-, Nd- and Sr-isotope compositions of the acid intrusives in Skye, North-west Scotland[14,26], indicate that Lewisian basement is a major component of their source. This may reflect overall higher temperatures in the lower crust in North-west Scotland at the time of basalt eruption than elsewhere in the North Atlantic Tertiary province.

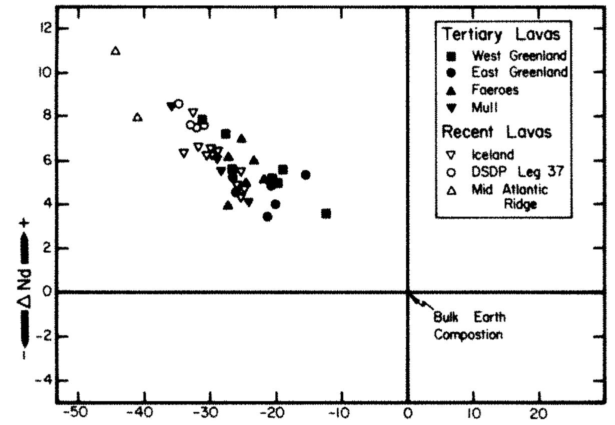

Fig. 3 Comparison of ΔNd and ΔSr values in Tertiary lavas from Baffin Island, east and west Greenland, Faeroes, Mull and Recent volcanics from the North Atlantic[4]. The solid square symbol is used for both Svartenhuk (west Greenland) and Baffin Island samples. ΔNd is the percentage deviation of the time-integrated Sm/Nd calculated from the measured $^{143}Nd/^{144}Nd$ ratio from the bulk Earth value, and ΔSr is the analogous parameter for Rb/Sr ratios[6].

Evolution of the North Atlantic source regions

The Nd- and Sr-isotope compositions of the basalts reported here and those of uncontaminated basalts from Northwest Scotland[14] all indicate derivation from source regions previously depleted in Rb relative to Sr and Nd to Sm. This observation is reflected in their uniformly positive ΔNd and negative ΔSr values. There is no evidence for the involvement of undepleted (or pristine) mantle source regions in the generation of basalts during the breakup of the North Atlantic, or indeed any basalt samples with either positive ΔSr or negative ΔNd values which are not readily explained by crustal contamination. The isotopic evolution of the subcontinental mantle sources sampled in the Tertiary seems to have been similar to that of some of the sub-oceanic sources sampled subsequently during the generation of the North Atlantic Ocean basin and particularly those represented by Icelandic volcanics erupted during more recent times (Fig. 3).

It is interesting to compare these conclusions with inferences concerning the chemical characteristics of subcontinental mantle based on geophysical observation and other continental volcanic suites. Both Jordan[7] and Oxburgh and Parmentier[8] have suggested that the subcontinental mantle must be overall more depleted in basaltic constituents than suboceanic mantle in order to stabilise it against convective disruption. If the degree of depletion of subcontinental mantle were uniform and had occurred over the same time scale as the depletion of present-day sub-oceanic mantle, continental basalts would have extreme values of ΔNd and ΔSr, similar to those of MORB. However, the isotopic characteristics of Tertiary North Atlantic basalts are more similar to those of some contemporary Icelandic basalts. If the Tertiary basalts were derived from the less depleted parts of the subcontinental mantle and other more-depleted and refractory areas did not melt, the basalts may convey a biased impression of the degree of depletion. Alternatively, and perhaps more likely, any depleted subcontinental mantle existing beneath the region before breakup may have been disrupted and replaced by less-depleted mantle material at a higher temperature and with a geological history similar to that of mantle material subsequently sampled during the evolution of the North Atlantic Ocean basin.

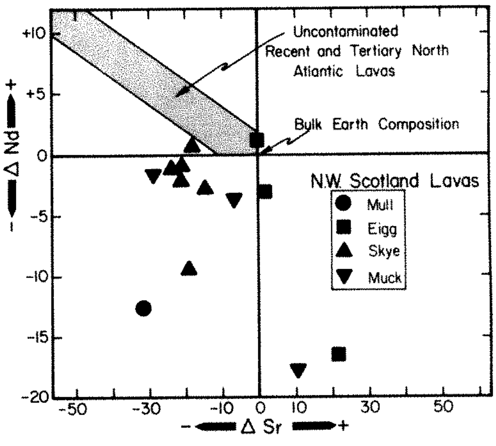

Fig. 4 Comparison of ΔNd and ΔSr parameters for Tertiary and Recent uncontaminated volcanics from the North Atlantic with Tertiary North-west Scotland volcanics inferred to have been contaminated by Lewisian basement[5]. ●, Mull; ■, Eigg; ▲, Skye; ▼, Muck.

Although the data obtained for the Tertiary North Atlantic basalts do not refute claims for the existence of undepleted or enriched subcontinental mantle source regions[2,9], they do clearly demonstrate that such potentially fertile regions were not available to produce basalts beneath the North Atlantic region at the time of incipient breakup in the early Tertiary.

We thank C. K. Brooks, B. Clarke and J. F. Brown for providing samples for this study and G. Wesselman and R. Cohen for technical assistance. The research was supported by US NSF grant EAR 75-20891.

A role for brown adipose tissue in diet-induced thermogenesis

Nancy J. Rothwell & Michael J. Stock

Department of Physiology, Queen Elizabeth College, University of London, London W8, UK*

Measurement of energy balance during voluntary overeating in rats unequivocally establishes the quantitative importance of diet-induced thermogenesis in energy balance. Like cold-induced thermogenesis, this form of heat production involves changes in the activity of the sympathetic nervous system and brown adipose tissue which suggest that this tissue may determine metabolic efficiency and resistance to obesity.

IT is generally accepted that heat production in mammals varies, but there is considerable controversy about the factors which cause this variation. Cold-adapted animals show non-shivering thermogenesis (NST) in which increased heat production, not associated with muscular activity, is mediated by the sympathetic nervous system and the animals show a pronounced increase in sensitivity to the thermogenic and lipolytic effects of catecholamines[1,2]. The capacity for NST is related to the presence of brown adipose tissue (BAT) which is found in many cold-adapted animals, hibernators and the neonates of many species, including man[3]. *In vivo* measurements indicate that, in spite of its small total mass (1–2% of body weight in the cold-adapted rat), under the influence of catecholamines BAT can receive as much as 34% of cardiac output and probably accounts for up to 60% of NST in the cold-adapted rat[4]. The significance of diet-induced thermogenesis (DIT) remains controversial. It is generally agreed that genetic obesity in mice is, in part at least, due to a failure of DIT[5,6] (associated also with a failure in NST[6,7]). There is also considerable evidence to show that variation in the energy cost of weight maintenance or weight gain can be induced in rats[8–11], pigs [8,12] and man [13–15] by manipulating dietary composition or intake. Miller [16] has argued that DIT has a central role in the regulation of energy balance, whereas Blaxter[17] has suggested that DIT is relatively unimportant. The controversy arises mainly from the use of abnormal animals and diets to produce differences in energy intake, in contrast to the voluntary overfeeding used in human studies. We have now developed a new dietary regimen that induces voluntary overeating of a balanced diet in normal animals and unequivocally demonstrates the quantitative importance of DIT in energy metabolism. As with NST, there is a sympathetic/catecholamine involvement and changes in the size and metabolism of BAT suggest that this tissue is an effector of DIT as well as NST.

'Cafeteria' feeding

We have used a dietary regimen originally described by Sclafani and Springer[18] which we call 'cafeteria' diet. Rats are offered various palatable food items in addition to normal laboratory stock diet. Each day four new food items are offered and the rat, which normally controls its intake precisely, is induced to overeat. On this diet animals rapidly become obese but when palatable food items are removed, and only stock diet is available, body weight rapidly returns to the level of animals fed stock diet throughout[19]. This reversible obesity seems to have no lasting effects on metabolism: three repetitive bouts of treatment do not affect subsequent ability to lose weight[20].

The degree of obesity obtained using the cafeteria diet varies and initially this was ascribed to a failure in some experiments to induce hyperphagia. However in all experiments where food intake was measured there was evidence for marked hyperphagia, suggesting that differences in weight gain were due to variations in heat production.

Adult male Sprague-Dawley rats (from Charles River) were allowed free access to water and a pelleted stock diet. Half of the animals were maintained on the cafeteria diet for 21 days after which all animals continued on stock diet only. Detailed measurements of energy balance were made on six animals from each group and the results are shown in Table 1. In spite of consuming 80% more energy, the weight gain of cafeteria-fed rats was only 27% greater than that of controls. The hyperphagia was due to a combination of a greater weight of food eaten per day and the higher energy density of the cafeteria foods, and was still apparent when energy intakes were corrected for differences in body size.

Analysis of body composition revealed that 93% of the excess weight gain of cafeteria rats consisted of fat deposition, resulting in a large increase in body energy content (Table 1). However, the energy cost of weight gain (g gain per MJ eaten) was significantly lower in cafeteria rats (11.23±0.55) than

Table 1 Energy balance data for control and cafeteria rats from day 0 to day 21

	Control	Cafeteria
Body weight gain (g)	103±7	131±8*
Body fat gain (g)	40±3	66±5†
Energy intake (kJ)	6,480±200	11,670±330‡
($kJ/W^{0.75}/day$)	650±10	1,140±30‡
Final body energy (kJ)	4,100±160	4,540±120*
Body energy gain (kJ) (days 0–21)	1,790±160	2,230±130*
Efficiency of gain (kJ gain per kJ eaten)	0.36±0.07	0.22±0.01†
Energy expenditure (kJ)	4,690±100	9,440±250‡
($kJ/W^{0.75}/day$)	470±10	930±20‡

Initial body weight (g) on day 0 was; control 318±4, cafeteria 315±4. Energy intake was estimated from (1) weight of stock diet (PRD, Christopher Hill Group Ltd) consumed and its metabolisable energy density (10.75 kJ per g, previously determined experimentally) and (2) the weight of each cafeteria food item consumed and the metabolisable energy density given in food composition tables[21]. These animals were killed on day 21, body composition determined by analysis and body energy calculated from this using values of 38.0 and 19.16 kJ per g for the energy value of fat and protein respectively[22]. A group of six animals were also killed on day 0, body energy content determined in the same way and this value subtracted from the final body energy content of the experimental animals in order to estimate body energy gain. The initial body composition of this baseline group and the experimental animals was also determined indirectly on day 0 using an *in vivo* tritium dilution method[23]. The composition of both experimental groups was identical and no different from that of baseline animals. Energy expenditure over the 21 days of the experiment was estimated by subtracting the body energy gain from the metabolisable energy intake $W^{0.75}$ = body weight $(kg)^{0.75}$. Mean values ±s.e.m., $n=6$, * $P<0.05$, † $P<0.01$, ‡ $P<0.001$ compared to controls.

controls (15.89 ± 0.67, $P < 0.01$) and body energy gain per unit intake was similarly reduced by 39% in experimental animals (Table 1). This contrasts with our report[24] that efficiency (g gained per MJ) was not significantly increased in cafeteria rats and may be due to inherent differences in metabolic efficiency between diverse groups of experimental animals. In a recent experiment with the same strain of rat from two different breeding colonies (Tuck, Essex and Charles River, Kent) the efficiency of weight gain of 'Tuck' rats fed the cafeteria diet was 12% greater than the stock fed controls, although not significantly so, whereas the efficiency of 'Charles River' cafeteria animals was 17% lower than their controls ($P < 0.01$). The genetic influence on metabolic efficiency is well known[25,26], but the above results illustrate that even within the same strain of rat, small differences in genetic and/or environmental background can exert a profound influence on the metabolic response to overfeeding.

Our studies show some parallel with those carried out in man, particularly the overfeeding experiments[13-15]. In human subjects, changes in the energy cost of weight gain have been ascribed to increases in DIT, and our energy balance results confirm a similar effect in the overfed rat. There was a 100% increase in the total energy expenditure of cafeteria-fed rats, a difference which is still apparent when the results are corrected for the greater body weight of these animals (Table 1). It is unlikely that such large differences in energy expenditure could be accounted for by activity which, at best, represents only a small fraction of energy expenditure in the rat and these adult rats were housed in pairs in cages designed to restrict activity. The differences in daily heat production observed would require prodigious activity (equivalent to each rat walking 6 km per day). It is also unlikely that these differences were due to the energy cost of the excess fat gain in cafeteria rats. Less than 8% of the extra energy expended by cafeteria rats could be accounted for in this way if a value of 14 kJ per g (ref. 27.) is assumed for the energy cost of fat gain.

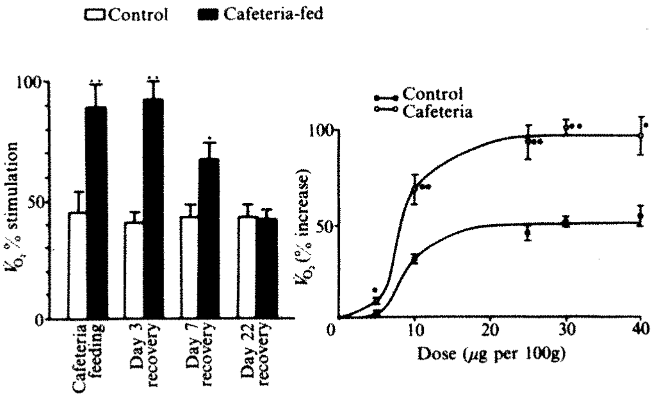

Fig. 1 *a*, Effect of noradrenaline on oxygen consumption in cafeteria and control animals. Adult, female Sprague-Dawley rats were fed the cafeteria diet for 28 days and noradrenaline sensitivity was measured on day 26. The cafeteria diet was withdrawn on day 28, allowing free access to stock diet and noradrenaline sensitivity was measured 3, 7 and 22 days later. Cafeteria rats were 50 g heavier than controls on day 26 and had completely returned to control weight by day 22 of recovery. Oxygen consumption was measured for 2 h before and after injection of noradrenaline (Levophed, 25 μg per 100 g body weight, s.c.). Results are presented as oxygen consumption after noradrenaline as a percentage of the pre-injection value. Mean values, bar denotes s.e.m. * $P < 0.05$, ** $P < 0.01$, compared to controls. *b*, Stimulation of resting oxygen consumption by various doses of noradrenaline. Adult female Sprague-Dawley rats were maintained on the cafeteria diet for 15 days and during this time gained 23 g excess weight compared to their free-feeding controls. Two days after withdrawal of the mixed diet resting oxygen consumption was determined for 2 h before and after administration of noradrenaline. One dose of noradrenaline was tested in four control and four experimental animals and the withdrawal of the cafeteria diet was staggered in order to facilitate these measurements. Mean values, bar denotes s.e.m., $n = 4$. * $P < 0.05$, ** $P < 0.01$, compared to controls.

Table 2 Resting oxygen consumption (ml/min/$W^{0.75}$) of control and experimental rats in response to propranolol, during and after cafeteria feeding

	Control	Cafeteria
Cafeteria feeding period		
Day 5	11.91 ± 0.41	14.48 ± 0.16†

Propranolol injected (day 2)		
Before	10.14 ± 0.14	12.30 ± 0.23
After	10.15 ± 0.19	10.88 ± 0.27
	NS	++

Resting oxygen consumption was measured in a closed circuit respirometer[28] for 2 h during the day, at a temperature of 29 ± 1 °C. On day 13 of cafeteria feeding and day 2 of the recovery period oxygen consumption was measured before and after injection of propranolol (0.5 mg per 100 g body weight s.c.). Resting values were obtained as described in ref. 29 and have been corrected for differences in body size. The same animals were used for these measurements throughout the 21 day cafeteria feeding period and the withdrawal of the mixed foods. Oxygen consumption was determined on the first 3 days of the recovery period since it is during this time that weight loss is most rapid and the measurement on day 13 was made when the body weight of the cafeteria rats had returned to control levels. Mean values ± s.e.m., $n = 6$: * $P < 0.05$, † $P < 0.01$, ‡ $P < 0.001$, compared to controls: ++ $P < 0.01$ compared to pre-injection value, NS not significant.

The association of lowered efficiency with increased DIT in the overfed animals was confirmed by measuring resting oxygen consumption ($\dot{V}_{O_2}$ (Table 2). Because these represent sample daytime measurements in resting animals they exclude the effects of activity and night-time feeding. Nevertheless, a 20–30% difference in $\dot{V}_{O_2}$ was consistently observed between control and experimental rats throughout the period of weight gain and, confirming our previous findings[19,20,24], also during the initial recovery period when cafeteria rats were losing weight rapidly. This sustained increase in DIT after the cafeteria diet was withdrawn is one of the most interesting effects of this treatment since during the recovery period animals are hypophagic[19,24]. Thermogenesis was then dependent on the degree of obesity and $\dot{V}_{O_2}$ returned to control levels as body weight declined to normal. This independence of DIT from the immediate energy intake indicates a chronic metabolic adaptation to hyperphagia and obesity.

Unlike previous demonstrations of DIT, our results clearly establish the cafeteria system as a method for inducing DIT in normal rats without resorting to nutritionally-unbalanced diets (such as low-protein diets) and we can now consider the metabolic origins of DIT using this model.

Metabolic changes

Increased sensitivity to the thermogenic effects of noradrenaline in cafeteria-fed rats[20] is illustrated in Fig. 1. In experimental animals the increase in $\dot{V}_{O_2}$ after noradrenaline was twice that seen in controls, both during the period of weight gain and when cafeteria feeding was stopped, after 3 days of weight loss: these differences diminished as the animals returned to control body weight. In those rats described in Table 1 there was also a greater sensitivity to noradrenaline during the period of weight gain with the control and cafeteria rats showing increases in $\dot{V}_{O_2}$ of 6% and 76% respectively. To confirm that differences in sensitivity to noradrenaline were not a reflection of the dose used, doses of 5–40 μg per 100 g body weight were tested (Fig. 1*b*). Cafeteria animals were more sensitive throughout the range: response was maximal for approximately the same dose given to both groups (25 μg per 100 g), whereas the lowest dose (5 μg per

100 g) produced a significant response in cafeteria rats only. There was no correlation between noradrenaline sensitivity and body fat content in either group ($r < 0.3$) indicating that the enhanced sensitivity was not simply a consequence of a greater fat mass.

There are many reports of enhanced sensitivity to the thermogenic effects of noradrenaline in animals exhibiting NST and the differences between warm and cold-adapted rats[30,31] are as great as those seen in control and cafeteria animals. The effects of increased sympathetic activity on oxygen consumption in cold adapted rats can be inhibited using agents that block catecholamine receptors[32] and might therefore be expected to have similar effects on DIT. Table 2 shows that the β-adrenergic blocking agent propranolol produced a significant decrease in the $\dot{V}_{O_2}$ of cafeteria rats while on the mixed diet and during the early recovery phase, but had no effect on the oxygen consumption of control animals. The changes in noradrenaline sensitivity and the effects of propranolol on $\dot{V}_{O_2}$ therefore indicate an increase in sympathetic activity in cafeteria-fed animals and suggest that the sympathetic nervous system is involved in the control of DIT as well as NST. Further support for this idea comes from the report by Young and Landsberg[33] of comparable increases in cardiac noradrenaline turnover between overfed rats and rats adapted to the cold.

Such results and the similarities between NST and DIT inevitably lead to the question of whether the same effector tissue is involved in the two types of thermogenesis. As stated above, the main effector tissue for NST is BAT. It has not previously been suggested that BAT plays a thermogenic role in any situation other than cold exposure. However, we have found increased deposits of BAT in the interscapular region of cafeteria rats and this would be consistent with other similarities we have noted between these rats and cold-adapted animals.

Because BAT is highly thermogenic it can be detected, particularly in the interscapular region, using the non-invasive technique of measuring surface temperature[34]. Surface and rectal temperatures were therefore measured in control and cafeteria rats before and after injection of noradrenaline 25 μg per 100 g (Fig. 2). Skin temperature was measured between the scapulae where large deposits of BAT are seen in cold-adapted rats and on the abdomen directly over the liver. Before injection of noradrenaline mean rectal and interscapular temperatures of cafeteria rats were, respectively, 0.6 and 0.8 °C higher than those of controls ($P < 0.001$) but abdominal temperature was similar in the two groups. Noradrenaline produced a marked rise in skin and rectal temperatures of experimental animals but did not significantly alter those of controls. The interscapular temperature increased by 1.3 °C after noradrenaline compared to only 0.7 °C for the abdomen, so that the interscapular temperature of cafeteria rats was significantly higher than abdominal after noradrenaline ($P < 0.001$). This marked increase in skin temperature over the interscapular BAT in cafeteria rats after noradrenaline indicates either an increase in heat production of this tissue and/or an elevated blood flow, both of which are seen in the cold-adapted rat after noradrenaline[4].

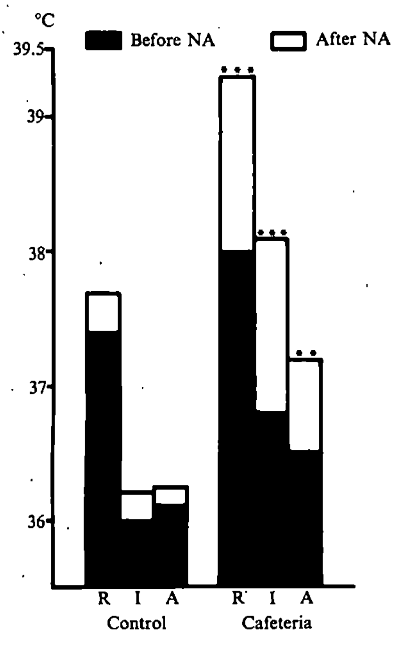

Fig. 2 Rectal (R), interscapular (I) and abdominal (A) temperatures of control and cafeteria rats before and after noradrenaline. Rectal and skin temperatures were measured on day 19 of cafeteria-feeding using thermocouples sensitive to 0.05 °C (Comark 1694 F) in an air-conditioned room at 24 ± 1 °C. Skin temperature was determined between the scapulae and on the abdomen just below the xiphisternum by taping a thermocouple over the surface of the skin and rectal temperature was measured by insertion of a plastic coated thermocouple 4 cm into the animal. Three readings were taken at 5 min intervals for each site before injection of noradrenaline (25 μg per 100 g body weight) and a further three measurements at 5-min intervals were carried out 1.5 h after administration of the drug. Mean values, $n = 6$. ** $P < 0.01$, *** $P < 0.001$, compared to pre-injection temperature.

Table 3 Brown adipose tissue weight, composition and *in vitro* release of free fatty acids (FFA)

	Control	Cafeteria
Interscapular BAT weight		
(mg)	266 ± 13	692 ± 28‡
(mg per 100 g body wt)	63 ± 3	156 ± 9‡
Interscapular BAT composition		
% Fat	36.3 ± 1.9	36.8 ± 2.3
% Fat-free dry wt	8.7 ± 0.8	9.8 ± 1.1
In vitro FFA release (μM FFA per mg per 2 h)		
Basal	5.54 ± 0.17	5.09 ± 0.29
Noradrenaline stimulated	7.33 ± 0.35	11.70 ± 0.59‡
% Increase	33 ± 7	132 ± 15‡

The fat content of brown adipose tissue was determined by ether extraction. Basal *in vitro* release of FFA was estimated using duplicate 50 mg samples. Each sample was incubated in 1 ml Earle's bicarbonate (pH 7.4, containing 2% bovine serum albumin), at 37 °C in a shaking water bath for 2 h. Stimulated FFA release was measured in another set of duplicates with noradrenaline (final concentration 2.5 μg ml^{-1}) added to the medium. After incubation the tissue was removed and the FFA content of the medium was determined by a micro-colorimetric method[35]. Mean values ± s.e.m., $n = 6$, ‡ $P < 0.001$ compared to controls.

These animals were killed after 21 days of cafeteria feeding and interscapular BAT was dissected out. The weight of tissue found in cafeteria rats was similar to that found in rats adapted to 5 °C[30,36] but was more than twice that found in controls (Table 3). The observed increase was due to an increase in active tissue mass rather than excessive lipid deposition (Table 3) suggesting a true hypertrophy in response to cafeteria feeding. Table 3 also shows that although basal release of free fatty acids (FFA) from interscapular BAT was similar for both groups, the stimulated release in the presence of noradrenaline (% increase) was four times greater in cafeteria rats.

Thus by various criteria (interscapular BAT mass, temperature response and lipolytic sensitivity to noradrenaline) it is possible to demonstrate an association between changes in BAT and DIT that resemble the changes seen in cold-adapted animals. The contribution of BAT thermogenesis to total heat production has yet to be quantified but there is a remarkable correlation between resting $\dot{V}_{O_2}$ of cafeteria rats and their interscapular BAT mass ($r = 0.8$, $n = 12$, $P < 0.001$) which is not apparent in control animals ($r = 0.45$, $n = 12$, not significant). If such a relationship were causal it would not necessarily exclude the participation of other tissues in the metabolic response to overfeeding and we have shown that there are increases in the lipolytic sensitivity of white adipose tissue to noradrenaline in cafeteria rats[20]. Nor can other thermogenic hormones, in particular the thyroid hormones be excluded. The role of the thyroid in NST is unclear (see ref. 1) but injections of thyroid hormones have been shown to induce hypertrophy of BAT, increase noradrenaline sensitivity and improve cold tolerance[30]. In addition, recent studies have demonstrated that circulating levels of triiodothyronine (T_3) are elevated in overfed human subjects[37] and in animals exhibiting DIT in response to low-protein diets[11,12]. It is therefore not surprising that plasma T_3 levels were elevated by 27% in cafeteria rats during mixed diet feeding (T_3 (ng ml^{-1}): control 0.89 ± 0.03, cafeteria 1.14 ± 0.08, $P < 0.01$). This difference was still apparent 4 days after the mixed diet was withdrawn when cafeteria rats were in fact hypophagic compared to controls but still had a higher oxygen consumption. These higher T_3 levels may not necessarily be directly responsible for the elevated heat production of cafeteria rats but could explain the hypertrophy of BAT and enhanced sensitivity to noradrenaline seen in these animals.

Brown fat in man

We have pointed out[38] that obesity induced by cafeteria feeding has several advantages over other experimental models of obesity (such as genetic, hypothalamic and drug-induced obesity). Apart from the fact that cafeteria feeding does not involve pathological and irreversible changes, it is perhaps the closest approximation to the human condition where, at least in some parts of the world, a varied and highly palatable diet encourages over-indulgence. In spite of this, many individuals remain lean, perhaps because they, like the rat, exhibit DIT. One major difference between the rat and man is that although adult man does possess some BAT[39,40] this was not considered to be thermogenically active. However, the association between DIT and BAT in the rat demands a reconsideration of the role of this tissue in all species, including man, and promoted us to undertake the experiment shown in Table 4. It was postulated that the existence of functional BAT in man could be identified by local changes in skin temperature during stimulation by a sympathomimetic agent such as ephedrine, which increases metabolic rate in man[41]. Ephedrine produces the largest increases in skin temperature in the neck and upper back—areas that correspond to BAT locations in the human neonate and adult[34,39]. The existence of these localised areas which are sensitive to ephedrine has also been confirmed using IR thermography (Fig. 3). These findings can be interpreted as evidence for functional BAT in man.

Conclusions

By adopting the cafeteria feeding system we have been able to demonstrate the existence and importance of DIT in energy metabolism. The striking similarities between DIT and NST suggest that these two phenomena may have a common metabolic origin in BAT. The importance of NST is mainly restricted to cold-adaption in small mammals. The role of BAT in man is not clear, but our findings now raise questions as to the advantages of possessing this energetically wasteful tissue. Confirmation of the thermogenic activity and quantitative significance of BAT in man must await more direct methods for studying local tissue heat production and blood flow but if BAT in adult man has an oxidative capacity similar to that of other species it could make a significant contribution to energy expenditure. Similarly, a defect in, or an absence of BAT would predispose to obesity. The finding[42] of a decreased thermogenic response to noradrenaline in constitutionally obese humans is similar to that reported in the genetically obese mouse[6]. If, as in the obese mouse, this loss of sensitivity is associated with a defect in BAT[43] the importance of this tissue in man will assume clinical significance.

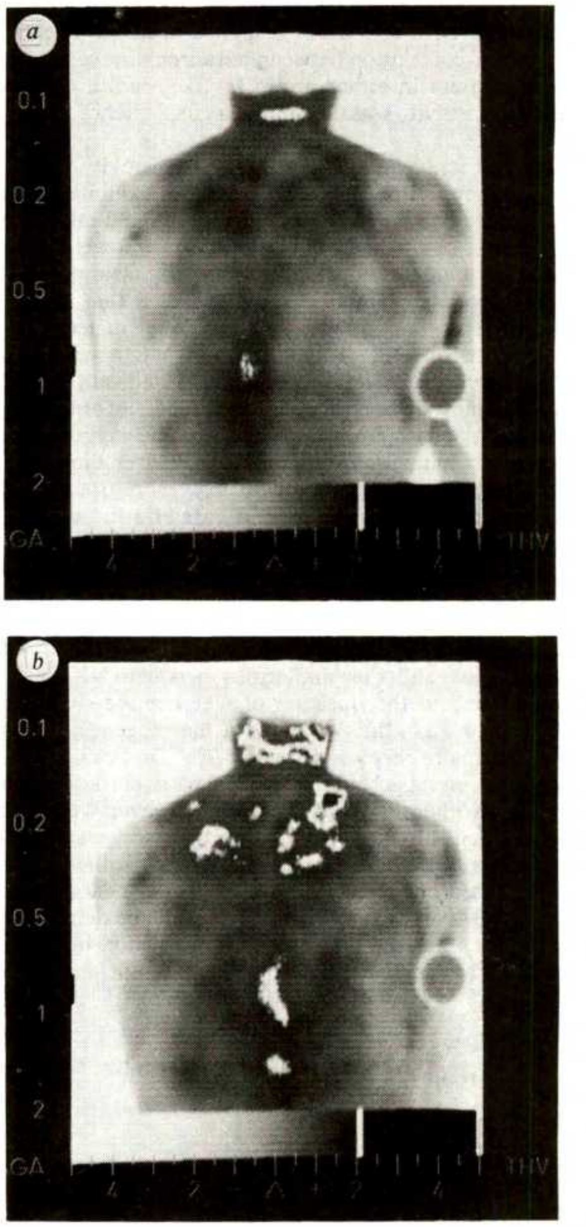

Fig. 3 IR thermograms of one subject before and after administration of ephedrine. IR thermograms (AGA Thermovision; 2–6 μm) were made after the subject had equilibrated for 12 min at a room temperature of 19 °C. Before taking ephedrine (*a*) the highest skin temperature recorded, which corresponds to the vertical bar on the lower scale, was 34.1 °C. The areas of skin isothermal to this temperature appear as white patches on the image. One hour after taking ephedrine (*b*) the areas at this temperature have increased but are concentrated between and above the scapulae and in the neck region. The subject was male, aged 36 yr and the dose of ephedrine was the same as in Table 4.

Table 4 Changes in skin temperature (Δ °C) following the oral administration of ephedrine

	Subject A	Subject B	BAT site
Nape of neck	0.4	0.8	+
Interscapular	0.7	0.6	+
Suprascapular	0.4	0.4	NE
Subscapular	0	0.5	NE
Lower spine	0.1	−0.1	NE
Abdomen	−0.1	−0.1	−
Sternum	0.4	0.7	+
Shoulder	−0.3	0.2	NE
Oral	0.1	−0.2	

Skin temperatures were recorded on the unclothed torso before and after taking ephedrine (1 mg per kg body weight), using a multi-channel electronic thermometer (Comark 1604). The skin thermocouples were kept in place for the duration of the experiment which was conducted in a room maintained at 25 °C. Subject A was male, aged 36 yr and subject B was female, aged 23 yr. The symbols in the column headed 'BAT site' refer to BAT locations in adult man as described by Heaton[39] (+, positive identification; −, negative; NE, not examined).

We thank John Stirling and John Rivers for useful discussions, Colin Jones (Physics Department, Royal Marsden Hospital) for performing the IR thermography and Sue Davies for technical assistance. This work was supported in part by the Rank Prize Fund.

Expression of the chromosomal mouse β^{maj}-globin gene cloned in SV40

Dean H. Hamer & Philip Leder

Laboratory of Molecular Genetics, National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, Maryland 20205

The complete chromosomal mouse β^{maj}-globin gene, including its intervening and flanking sequences, has been cloned in the monkey virus SV40. The mouse gene is transcribed, processed and translated in infected monkey kidney cells to yield mouse β^{maj}-globin.

WE have identified several conserved sequences in the chromosomal DNA of cloned mouse α- and β-globin genes that may have an important role in their ordered expression and in the processing of their initial transcripts[1-5]. Despite the fact that these sequences have been preserved during several hundred million years of separate evolutionary development, we cannot be certain of their function or importance until they, or mutants derived from them, have been tested in an appropriate biological system. Our first approach to the development of such tests has involved the use of animal viruses as vectors of chromosomal genetic information. Here, we have inserted the complete genomic mouse β^{maj}-globin gene into the monkey virus SV40 and used the resulting recombinant to infect cultured monkey kidney cells. Despite the species and cell-type differences, the mouse globin signals for RNA splicing, polyadenylation and translation are recognised in this host, and substantial quantities of mouse β^{maj}-globin are produced. Thus, the SV40–monkey cell system seems to provide a useful and logical extension of the recombinant DNA technology, returning the cloned gene to a cell in which its function can be tested.

The present experiment was based on our previous experience with SV40 hybrids carrying both prokaryotic and eukaryotic DNA fragments. Initially, we used an *Escherichia coli* suppressor tRNA gene to develop the SV40 late region deletion vehicle system. We found that such vehicles could be used to propagate the foreign DNA either as virus in productively infected cells[6,7], or as a stable genetic element in transformed or persistently infected cells[8,9]. Subsequently, we inserted a rabbit β-globin coding sequence, derived from a cloned reverse transcript, into two different sites in the SV40 late region[10]. As anticipated, expression of the cDNA gene into a stable, translatable mRNA required the retention of the appropriate signals for mRNA processing (and possibly translation) in the viral vector. A similar conclusion was reached by Mulligan *et al.*[11], who inserted the rabbit sequence at a different site in the viral late region. Most recently, we constructed viruses carrying a portion of the mouse β^{maj}-globin gene, and provided evidence for the use of a globin splice junction and polyadenylation site when the sense strand of the gene was transcribed from the viral late region promoter[12]. However, because of the limitations of our biochemical analyses, we could not be certain that the processing reactions were occurring at exactly the appropriate sites. This encouraged us to insert the complete chromosomal gene into SV40, thereby providing a more stringent test for functional mRNA synthesis—translation into authentic globin.

Construction of an SV40 recombinant carrying the complete chromosomal mouse β^{maj}-globin gene

In the recombinant virus described here, the complete chromosomal mouse β^{maj}-globin gene, including its intervening and adjacent flanking sequences, replaces the viral late gene region. The gene is inserted in the same orientation as the SV40 late protein coding sequences. Therefore, readthrough transcription from the strong viral late region promoter, which is preserved in the vector, generates the globin coding sequence rather than its complement. The construction of this recombinant, depicted in Fig. 1, involved four steps: preparation of the appropriate globin and viral vector DNA segments; ligation *in vitro* of these segments to form linear recombinant molecules with the appropriate orientation; cyclisation of the recombinant genomes *in vivo* following DNA infection of cultured monkey kidney cells; and isolation of a clone of virus having the desired structure.

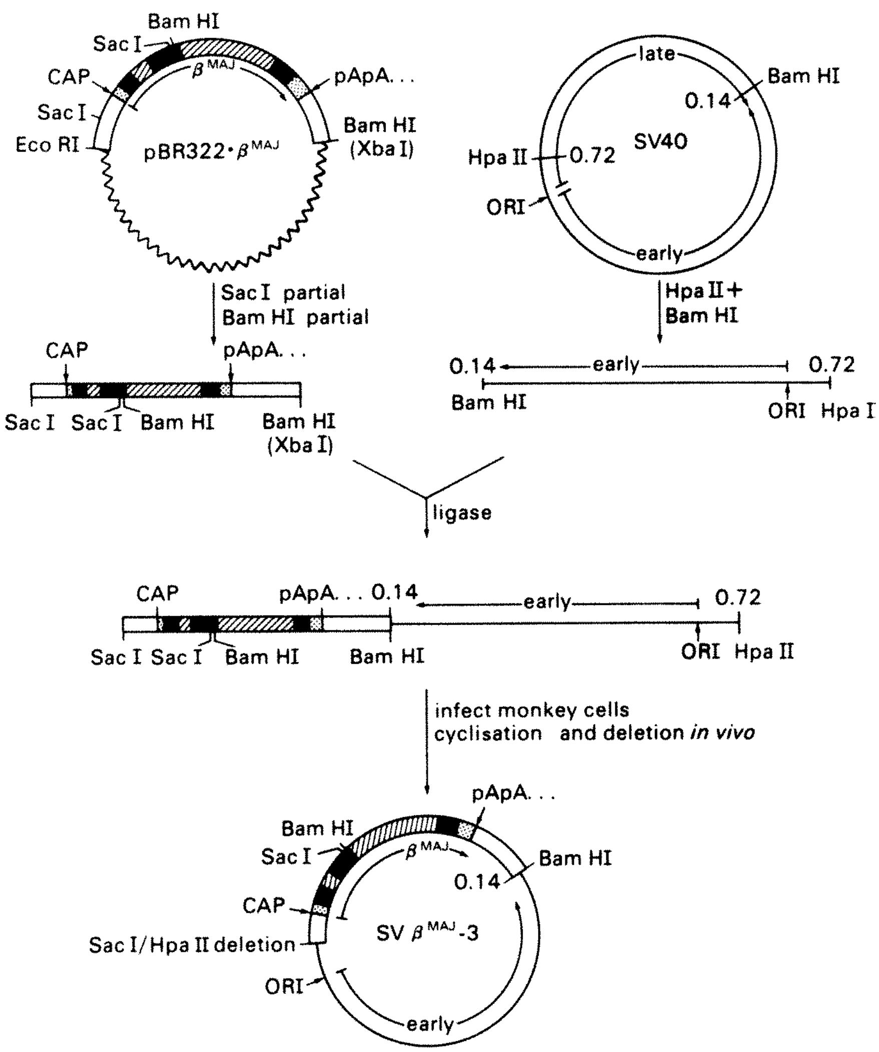

Fig. 1 Construction and propagation of the SV40–mouse β^{maj}-globin gene recombinant. Open bars: mouse β^{maj}-globin gene flanking sequences; stippled bars: globin transcribed, untranslated sequences; solid bars: globin coding sequences; hatched bars: globin intervening sequences; wavy lines: plasmid sequences; solid lines: SV40 sequences. The methods used for DNA preparation, restriction endonuclease cleavage, isolation of fragments on gels, ligation, DNA infection of African green-monkey kidney cells and preparation of virus stocks have been described elsewhere[6,10,12]. **The chromosomal β^{maj}-globin gene fragment:** The upper left diagram shows the structure of pBR322·β^{maj}, which contains the mouse chromosomal β^{maj}-globin DNA sequences from an *Eco*RI site located 1,200 base pairs upstream from the globin cap site to an *Xba*I site located 600 base pairs downstream from the poly(A) addition site. This plasmid was derived from the original recombinant pMB9·β^{maj} (ref. 2) by linking the *Xba*I site to a synthetic dodecamer containing a *Bam*HI site, cloning the resulting *Bam*HI–*Bam*HI fragment in pBR322 (ref. 26), then reconstituting the gene by insertion of the 5′-*Eco*RI–*Bam*HI globin gene fragment. This plasmid was partially digested with *Sac*I and *Bam*HI to generate the 2,400-base pair fragment that was cloned in SV40. **The SV40 vector:** The upper right diagram shows the structure of wild-type SV40 DNA including the direction of transcription of the late and early mRNAs, the origin of viral DNA replication (ORI), and the cleavage sites for *Bam*HI and *Hpa*II relative to the *Eco*RI site at 0.00/1.00 map units[27,28]. The DNA was cleaved with *Bam*HI and *Hpa*II to generate the 3,000-base pair vector fragment. This fragment retains the entire early region, the origin of replication and the sequences corresponding to the 5′- and 3′-termini of the viral late mRNAs; it lacks the coding sequences for the late viral proteins VP1, VP2 and VP3. **The recombinant molecule:** A mixture containing 24 μg of the globin gene fragment and 18 μg of the SV40 vector fragment was treated with DNA ligase, then electrophoresed through a 1% agarose gel to purify the 5,400-base pair linear recombinant genome. This molecule, formed by joining the two *Bam*HI termini, contains the globin coding sequences on the same strand normally occupied by the viral late gene coding sequences. **Propagation:** Approximately 10 ng of the purified recombinant DNA mixed with 70 ng of DNA from the temperature-sensitive early gene mutant helper tsA_{239} and used in a DNA plaque infection of monkey kidney cells at 41 °C. Fifty complementation plaques were picked and used to prepare virus stocks. DNAs from these stocks were immobilised on nitrocellulose filters and tested for hybridisation to a probe containing globin gene 5′-flanking sequences (see Fig. 2 legend). Of three isolates showing unequivocal hybridisation, one was kept for further analysis and designated SVβ^{maj}-3.

We originally cloned the β^{maj}-globin gene in bacteriophage λ as part of a 7,000-base pair fragment of chromosomal DNA[1]. Complete nucleotide sequence analysis of this gene revealed that it is divided into three discontinuous coding segments by two intervening sequences of DNA[5]. The shorter intervening sequence is 116 base pairs long and interrupts the gene between amino acid codons 30 and 31, whereas the longer is 646 base pairs and interrupts between amino acid codons 104 and 105. Because the maximum amount of DNA which can be inserted in the SV40 late region is only 2,500 base pairs, it was not possible to use the whole 7,000-base pair globin fragment. Instead, we prepared a 2,400-base pair subfragment extending from a *Sac*I site, located 430 base pairs upstream from the 5′-end of the globin mRNA sequence, to an *Xba*I site, located 600 base pairs downstream from the 3′-end of the mRNA sequence. This fragment contains, in addition to the entire globin coding sequence, the sequences adjacent to the sites at which the cap is added to the 5′-end and poly(A) to the 3′-end of the globin mRNA. It also contains two RNA splice junctions and their corresponding intervening sequences. To facilitate the preparation of this fragment and its cloning in SV40, we converted the *Xba*I site to a *Bam*HI site by ligation to a synthetic oligonucleotide linker, then subcloned a restriction fragment containing the relevant sequences in a plasmid vector.

The viral vector segment, which was prepared by cleavage of wild-type SV40 DNA with *Bam*HI at map position 0.14 and *Hpa*II at map position 0.72, retains the viral origin of replication, the entire early gene region and the sequences corresponding to the extreme 5′- and 3′-termini of the late 16S and 19S mRNAs. It lacks the coding sequences for the viral late proteins VP1, VP2 and VP3 and the splice junctions for their corresponding mRNAs[13–16]. We have previously demonstrated that various foreign DNA fragments inserted in this vector are efficiently transcribed from the SV40 late promoter, but the resulting transcripts are not appropriately processed and are rapidly degraded in the cell[10]. This might be because the viral late mRNA splice junctions are absent from the hybrid virus. Recombinants formed with this vector lack the viral late genes and are therefore defective. However, because the recombinants retain a functional early gene region, they can be propagated by co-infection with a temperature-sensitive early gene mutant virus as helper[6,7,34]. When such mixed infections are carried out at the non-permissive temperature, progeny virus is produced only by those cells infected with both the recombinant, which provides functional early gene product, and the helper, which provides late gene products.

The globin and viral DNA segments, both of which had one cohesive *Bam*HI terminus, were joined by treatment with DNA ligase to form a linear recombinant molecule that was purified by electrophoresis in an agarose gel. As shown in Fig. 1, the globin gene could join the vector in only one orientation, such that the globin coding sequence is on the strand normally occupied by the viral late protein coding sequences. The resultant recombinant molecule is about 150 base pairs longer than wild-type DNA and has non-complementary termini. However, previous experiments indicated that such molecules could cyclise *in vivo*, and that this is frequently accompanied by the generation of deletions around the junction between the viral and foreign DNAs (D.H.H., unpublished results). Accordingly, the recombinant DNA preparation was mixed with DNA from a temperature-sensitive early gene mutant as helper, and used in a DNA infection of cultured kidney cells. As anticipated, this mixed infection yielded a substantial number of complementation plaques, whereas infection with equivalent amounts of the recombinant or helper DNAs alone did not.

To identify a clone of virus having the desired structure, we prepared virus stocks from these plaques and tested their DNA for hybridisation to a globin probe containing the globin mRNA cap site and the 5′-genomic flanking sequences (see Fig. 2). Of the first 50 plaques tested, three showed unequivocal hybridisation. Presumably, the others had either suffered deletions extending past the 5′-end of the globin gene, or contained only low levels of recombinant virus. One of the positive clones, designated SVβ^{maj}-3, was kept for further analysis. This hybrid multiplies quite efficiently in monkey kidney cells. In our standard conditions of infection, the ratio of intracellular recombinant to helper genome is about 1 : 1.

An analysis of SVβ^{maj}-3 by restriction endonuclease cleavage and gel blot hybridisation (Fig. 2) confirmed that it had the structure expected from its manner of construction and selection. Although the recombinant has the same length as the helper, we were able to purify its DNA because it contains no *Eco*RI sites and one *Sac*I site, whereas the helper contains one *Eco*RI site and no *Sac*I sites. By digestion with the appropriate endonucleases, we showed that the recombinant has deleted 150 base pairs from the 5′-end of the original globin fragment, leaving 280 base pairs of genomic flanking sequence 5′ to the mRNA cap site. Less than 14 base pairs are deleted from the SV40 vector, leaving the predominant viral late mRNA cap sites intact. Thus, SVβ^{maj}-3 contains the complete mouse β^{maj}-globin gene in the sense orientation relative to the viral late region promoter.

Transcription and processing of globin mRNA

Monkey cells infected with SVβ^{maj}-3 efficiently synthesise a stable globin mRNA that is spliced and polyadenylated at the appropriate globin gene sites. However, most of this RNA is initiated at the SV40 late promoter region rather than the globin promoter. Evidence for this is derived from gel transfer hybridisation experiments and the translation studies described below.

To characterise the globin RNA made in infected monkey cells, poly(A)-containing RNA was purified[13,14], denatured[15], electrophoresed through an agarose gel, transferred and covalently attached to diazobenzyloxymethyl paper[16], then hybridised with various ^{32}P-labelled DNA probes to reveal the positions of the separated RNAs (Fig. 3). Hybridisation with total SV40 DNA as probe yielded two bands corresponding to

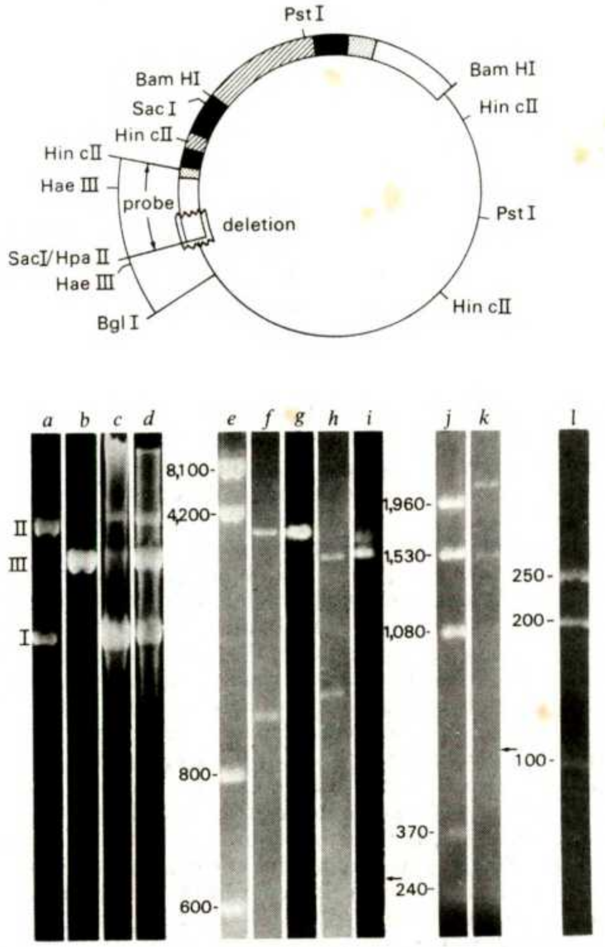

Fig. 2 Structural analysis of the SV40-mouse β^{maj}-globin gene recombinant. The upper diagram is a restriction endonuclease cleavage map of the recombinant virus SVβ^{maj}-3. Solid lines: SV40 sequences; open bars: globin gene flanking sequences; stippled bars: globin gene transcribed, untranslated sequences; solid bars: globin gene coding sequences; hatched bars: globin gene intervening sequences. The bottom panels show an analysis of the recombinant virus by restriction endonuclease cleavage and gel transfer hybridisation. A mixture of SVβ^{maj}-3 recombinant plus *tsA*$_{239}$ helper DNA was prepared by the method of Hirt[29] from monkey kidney cells that had been infected with the recombinant plus helper stock for 48 h at 40 °C. To prepare pure SVβ^{maj}-3 DNA, this mixture was digested with *Eco*RI, which has one site in the helper but none in the recombinant, and the resistant recombinant genomes were recovered as covalently closed circles as shown in track *d*. This preparation was digested with *Sac*I, which has one site in the recombinant but none in the helper, and the linear recombinant molecules were further purified by electrophoresis through a 1% agarose gel. A fragment containing the deleted junction between the globin and SV40 fragments was prepared by digestion with *Hin*cII plus *Bgl*I as shown in the diagram and electrophoresis of the resulting fragments through a 2% agarose gel. Tracks *a–d* were electrophoresed through 1% agarose gels, *e–i* through 1.4% agarose gels, *j*, *k* through 2% agarose gels, and *l* through an 8% acrylamide gel. Tracks *a–f*, *h* and *j–l* are photographs of ethidium bromide-stained gels. Tracks *g* and *i* are autoradiographs of nitrocellulose transfer strips that were hybridised to a pMB9 · βG2/*Sac*I–*Hin*cII probe containing flanking and transcribed, untranslated sequences from the 5′-portion of the globin gene (see upper diagram). Each track represents the following: *a*, undigested wild-type SV40 DNA. The positions of covalently closed circular (form I), nicked circular (form II) and linear (form III) SV40 are shown to the left; *b*, *Eco*RI digest of wild-type SV40 DNA gives linear molecules; *c*, undigested SVβ^{maj}-3 plus *tsA*$_{239}$ DNA; *d*, *Eco*RI digest of SVβ^{maj}-3 plus *tsA*$_{239}$ DNA gives about 50% resistant form I recombinant molecules and 50% sensitive form III helper molecules; *e*, *Sac*I plus *Pst*I digest of pMB9 · βG2 DNA gives marker fragments with lengths (in base pairs) shown to the left; *f*, *Bam*HI digest of SVβ^{maj}-3/*Sac*I DNA gives 3,700- and 1,500-base pair fragments; *g*, transfer of track *f* showing hybridisation to 3,700-base pair fragment; *h*, *Pst*I digest of SVβ^{maj}-3/*Sac*I DNA gives 3,000-, 1,570- and 630-base pair fragments. The position of the 630-base pair fragment, which can be seen only faintly in this reproduction, is indicated by the arrow to the right; *i*, transfer of track *h* showing hybridisation to 3,000-base pair fragment; *j*, *Hin*cII digest of wild-type SV40 DNA gives marker fragments with lengths (in base pairs) shown to the left; *k*, *Hin*cII digest of SVβ^{maj}-3/*Sac*I DNA gives fragments of 2,100, 1,530, 1,080 and 580 base pairs. The position of the 580-base pair fragment, which can be seen only faintly in this reproduction, is indicated by the arrow to the right; *l*, *Hae*III digest of the SVβ^{maj}-3/*Hin*cII–*Bgl*I junction fragment gives three fragments with the lengths (in base pairs) shown to the left. The lengths of these fragments were estimated by their mobility relative to several sequenced SV40 and globin gene fragments (not shown). There are single *Hae*III sites in the globin gene sequence between the *Hin*cII site and the deleted *Sac*I site and in the SV40 sequence between the *Bgl*I site and the deleted *Hpa*II site. Because *Hae*III digestion of the junction fragment yields three fragments, both *Hae*III sites must be preserved. The *Hae*III site in SV40 is 15 base pairs from the *Hpa*II site. Therefore, the deletion must cover less than 14 base pairs of SV40 sequence and 150–164 base pairs of globin gene flanking sequence.

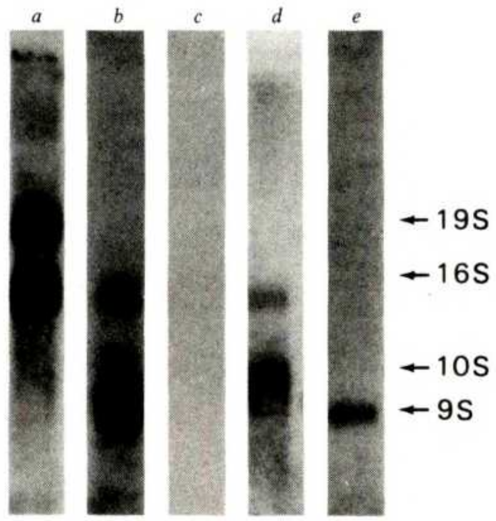

Fig. 3 Gel transfer hybridisation analysis of the globin RNA made in monkey cells infected with the SV40–mouse β^{maj}-globin gene recombinant. **RNAs and hybridisation:** A confluent monolayer of about 2×10^7 monkey kidney cells was infected with 5 ml of the SVβ^{maj}-3 plus $\underline{tsA_{239}}$ stock and incubated for 48 h at 40 °C. Total cell poly(A)-containing RNA was prepared by extraction with hot phenol[13] and oligo(dT)–cellulose chromatography[14], denatured with glyoxal[15], electrophoresed through a 1.5% agarose gel and transferred to diazobenzyloxymethyl paper[16]. Each lane contains 10% of the total sample. The resulting imprints were preincubated, hybridised with approximately 0.1 ng of ^{32}P-labelled, nick-translated DNA probe (25–50 c.p.m. per pg), washed and autoradiographed[10,16]. Globin mRNA was prepared from reticulocytes obtained from anaemic mice. **Probes** (see maps, Figs 1, 2): The globin probes were prepared by cleavage of the plasmid pMB9 · MβG2, which contains the entire 7,000-base pair chromosomal mouse β^{maj}-globin fragment[2]. The globin coding sequence probe contained 900 base pairs extending from the *Pst*I site 75 base pairs upstream from the 3′-coding segment to the *Xba*I site 600 base pairs downstream from the poly(A) addition site. The globin intervening sequence probe contained 600 base pairs extending from the *Bam*HI site 18 base pairs upstream from the large intervening sequence to the *Pst*I site 75 base pairs upstream from the 3′-coding segment. Control experiments with globin mRNA show that hybridisation of the 18 base pairs of coding sequence included in this intervening sequence fragment would not be detected in our conditions of hybridisation, washing and autoradiography. Wild-type SV40 DNA was prepared as described previously[6]. The SV40 late mRNA leader probe contained 250 base pairs extending clockwise from the *Bgl*I site at 0.67 map units in the *Hpa*II site at 0.72 map units. Each track represents the following: *a*, SVβ^{maj}-3 RNA hybridised with total SV40 DNA probe; *b*, SVβ^{maj}-3 RNA hybridised with globin coding sequence probe; *c*, SVβ^{maj}-3 RNA hybridised with globin intervening sequence probe; *d*, SVβ^{maj}-3 RNA hybridised with SV40 late mRNA leader sequence probe; *e*, globin mRNA (10 ng) hybridised with globin coding sequence probe.

the viral late 16S and 19S mRNAs, presumably due to transcription of the helper virus. When a fragment containing globin coding sequences was used as the probe, we detected a strong globin RNA band at approximately 10S, indicating molecules up to 300 bases longer than authentic globin mRNA (800 bases). This RNA did not hybridise with a probe derived from the large globin intervening sequence, indicating that it has been eliminated and that the second globin splice junction functioned properly in the infected cells. Because the globin RNA is efficiently translated into mouse β^{maj}-globin (see below), it is clear that the first splice junction is also functional and that both splicing reactions are accurate. To determine whether this RNA was initiated at the globin gene promoter or at the upstream viral promoter, we used as probe an SV40 fragment containing the viral late mRNA leader sequences. This probe hybridised strongly to the ~10S globin RNA band, indicating that most of these molecules arise from transcription initiation at the viral promoter. This may also explain the length heterogeneity of the globin RNA as the 5′-viral leader segments are known to be quite variable in length[17,18]. The SV40 leader probe also detected a 16S band and a very faintly hybridising 19S band (not visible in the reproduction of Fig. 3, lane *d*) which probably represents helper virus transcription.

In addition to the ~10S globin RNA, using the coding sequence probe we routinely detected a 16S (1,600 base) band comprising about 15% of the total globin-specific RNA. This RNA is at least partially spliced as shown by its failure to hybridise to the globin large intervening sequence probe. We suspect, but have not proved, that this species results from readthrough past the globin polyadenylation site to the downstream viral polyadenylation site. A similar situation was encountered in our more detailed studies of a recombinant carrying a segment from the 3′-portion of the mouse β^{maj} gene[12].

Judging from the intensities of the bands shown in Fig. 3, we estimate that the steady-state level of the mouse globin RNA produced in monkey cells compares favourably with that of viral late mRNA. Assuming that the globin and late viral mRNAs are initiated at the same rates from the SV40 late promoter, this indicates that the globin RNA is as stable as late viral mRNA. We estimate that approximately 5% of the total cell poly(A)-containing RNA is globin RNA, representing roughly 200,000 molecules per cell.

Mouse β^{maj}-globin is synthesised by infected monkey cells

Monkey kidney cells infected with SVβ^{maj}-3 synthesise a protein which we have identified as mouse β^{maj}-globin by immunoprecipitation, two-dimensional electrophoresis and tryptic fingerprint analysis. These tests indicate that the mouse globin mRNA is accurately spliced in monkey cells, and that the mouse gene translational signals are functional.

Figure 4 (lanes *a–h*) shows an experiment in which monkey cells were infected with either the SVβ^{maj}-3 plus helper stock or with no virus or wild-type SV40 as controls, incubated until late in the lytic cycle, then labelled for 1 h with ^{35}S-methionine. Sonic extracts were prepared, and a portion of each was electrophoresed through a polyacrylamide-SDS gel, which separates proteins according to their molecular weight[19]. As might have been anticipated from the fact that SV40 does not shut down host cell protein synthesis, the resulting autoradiograms showed a complex variety of proteins in which the globin region of the gel was obscured by host bands. However, when the cell proteins were first immunoprecipitated with purified goat anti-mouse β-globin antibody, we detected a band with the same mobility as authentic mouse globin in the SVβ^{maj}-3-infected cell extract but not in the mock or wild-type SV40-infected cell extracts. (The additional bands seen in these lanes were also seen using anti-SV40 T-antigen serum, and apparently result from artefactual trapping during the immunoprecipitation procedure.) The exact co-migration of this band with authentic mouse β^{maj}-globin was confirmed by a mixing experiment (Fig. 4, lane *h*).

The identity of this protein as mouse β^{maj}-globin is supported by a two-dimensional electrophoresis experiment (Fig. 4, lanes *i–m*). Extracts were prepared and immunoprecipitated as described above, unlabelled mouse globin was added to the eluted proteins and the mixtures were submitted to non-equilibrium *p*H gradient gel electrophoresis, which separates proteins according to their isoelectric points[20]. When the proteins co-migrating with mouse β^{maj}-globin, identified by staining, were eluted and electrophoresed through a polyacrylamide-SDS gel, we detected a strong globin band in the SVβ^{maj}-3-infected preparation but not in the mock or wild-type SV40-infected preparations. A mixing experiment (Fig. 4, lane *m*) confirmed the co-migration of this band with authentic globin. Note that the non-equilibrium *p*H gradient gels used in this experiment are capable of separating proteins that differ by only a single charge unit[20].

Tryptic fingerprint analysis provided further evidence that the protein encoded by SVβ^{maj}-3 is mouse β^{maj}-globin. The globin band from SVβ^{maj}-3-infected cells was purified by immunoprecipitation and polyacrylamide-SDS gel electrophoresis, digested with trypsin and submitted to two-dimensional chromatography on a cellulose thin layer plate[21,22]. The resulting autoradiogram (Fig. 5) showed two spots with the same relative positions as those found in a digest of authentic mouse

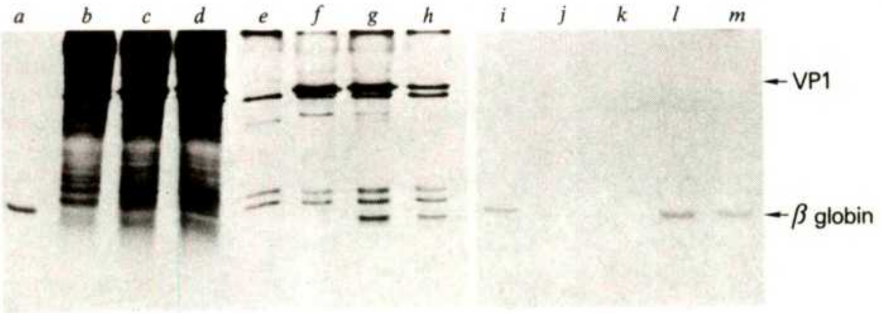

Fig. 4 Production of mouse β^{maj}-globin in monkey cells infected with the SV40-mouse β^{maj}-globin gene recombinant. **Proteins:** Confluent monolayers of about 2×10^7 monkey cells were treated with 1 ml of medium, wild-type SV40 or the SVβ^{maj}-3 plus tsA_{239} stock and incubated for 48 h at 40 °C. The cells were washed three times with methionine-free medium, then labelled for 1 h with 200 μCi of ^{35}S-methionine (516 Ci mmol^{-1}, NEN) in 1 ml of methionine-free media. After washing twice in ice-cold phosphate-buffered saline (PBS), the cells were scraped off the plates in PBS, collected by centrifugation, resuspended in 0.8 ml of PBS containing 1% Triton X-100 and 0.5% sodium deoxycholate, sonicated for 1 min at full power in a Heat Systems sonicator, and centrifuged at 12,000*g* for 30 min. The supernatants were recovered and analysed as described below. To prepare authentic mouse β^{maj}-globin, Friend erythroleukaemia cells were induced with 1% dimethyl sulphoxide for 3 d, labelled with 25 μCI ml^{-1} ^{35}S-methionine for 12 h, then lysed by freeze-thawing. Haemoglobin was purified on a carboxymethyl cellulose column and converted to globin by precipitation with 2% HCl in acetone[30]. Pure β^{maj}-globin chains were prepared by carboxymethyl cellulose column chromatography in the presence of 8 M urea[31]. **Immunoprecipitation:** 10 μl of heparin (10 mg ml^{-1}), 10 μl of normal goat serum and 50 μl of a 10% suspension of heat-killed formalin-fixed *Staphylococcus aureus* Cowen I bacteria were added to 500 μl of cell extract[32]. Following 30 min on ice, the bacteria were removed by centrifugation, the supernatant was added to a predetermined excess of purified goat anti-mouse β-globin antibody and incubated 12 h at 4 °C. Then, 50 μl of *S. aureus* suspension was added, the mixtures were kept at 4 °C for 1 h and the bacteria collected by centrifugation. The pellet was washed three times in PBS containing 1% Triton X-100 and 0.5% deoxycholate. A 20% aliquot of each sample was resuspended in 25 μl of SDS sample buffer[19], boiled for 5 min, centrifuged to remove the bacteria, then analysed by polyacrylamide-SDS gel electrophoresis. The remainder of each sample was resuspended in 100 μl of non-equilibrium *p*H gradient electrophoresis gel sample buffer[20], mixed with 5 μg of unlabelled mouse globins, incubated for 1 h at room temperature, centrifuged to remove the bacteria, then analysed by two-dimensional electrophoresis. **Gel electrophoresis:** 20% polyacrylamide-SDS gels were prepared, run and fluorographed as described elsewhere[19,33]. Non-equilibrium *p*H gradient gels[20] were prepared in 0.6 × 10 cm tubes and electrophoresed at 400 V (constant voltage) for 3 h. The gels were soaked in 50% methanol for 24 h, stained in 0.01% Coomassie brilliant blue, 50% methanol and 12.5% acetic acid for 15 min, then destained in 7% methanol and 1.25% acetic acid for 18 h. The region of the gel containing mouse β^{maj}-globin (well separated from β^{min}- and α-globin) was excised and the proteins eluted by electrophoresis, precipitated with 2% HCl in acetone, resuspended in 50 μl of SDS sample buffer, boiled for 5 min and electrophoresed through a polyacrylamide-SDS gel. **Quantification of globin synthesis:** 0.67% of the trichloroacetic acid-precipitable radioactivity in the extract from SVβ^{maj}-3-infected cells was recovered in the immunoprecipitate. Of this, 15% was in the globin band as determined by densitometry of the autoradiogram (track *g*). Thus, 0.67% × 5% = 0.1% of the ^{35}S-methionine incorporated during the 1-h pulse was found in globin. Tracks *a*–*h* are one-dimensional, polyacrylamide-SDS gel analyses of total cell extracts and immunoprecipitates. Tracks *i*–*m* are the second dimension from the two-dimensional analyses (non-equilibrium *p*H gradient gel electrophoresis followed by polyacrylamide-SDS gel electrophoresis) and were run on a separate polyacrylamide-SDS gel. Each track represents the following *a*, mouse β^{maj}-globin; *b*, total mock-infected cell extract; *c*, total wild-type SV40-infected cell extract; *d*, total SVβ^{maj}-3-infected cell extract; *e*, immunoprecipitate of mock-infected cell extract; *f*, immunoprecipitate of wild-type SV40-infected cell extract; *g*, immunoprecipitate of SVβ^{maj}-3-infected cell extract; *h*, mixture of mouse β^{maj}-globin and immunoprecipitate of SVβ^{maj}-3-infected cell extract (one-half the amounts applied to tracks *a* and *g* were mixed after immunoprecipitation and elution); *i*, mouse β^{maj}-globin; *j*, mock-infected; *k*, wild-type SV40-infected; *l*, SVβ^{maj}-3-infected; *m*, mixture of mouse β^{maj}-globin and SVβ^{maj}-3-infected samples (one-half the amounts applied to tracks *i* and *l* were mixed after immunoprecipitation elution).

β^{maj}-globin prepared from induced Friend erythroleukaemia cells. The identity of the peptides from the SVβ^{maj}-3 protein with authentic β^{maj}-globin was confirmed by fingerprinting a mixture containing equal amounts of radioactivity from both samples. Presumably, the two spots detected represent the two internal methionine-containing tryptic peptides of β^{maj}-globin[23]. The globin gene also encodes an N-terminal methionine which is removed in globin-producing cells. Because only the expected two spots were observed in the SVβ^{maj}-3 protein digest, we conclude that the monkey cells have appropriately removed the N-terminal methionine. Note also that one of the methionine-containing peptides (Leu 105–Lys 121) lies within the third coding sequence immediately after the second splice junction (Arg 104–Leu 105). This provides further evidence for accurate splicing of the mouse globin mRNA in monkey cells.

We estimate that the mouse β^{maj}-globin accounts for approximately 0.1% of the ^{35}S-methionine incorporated during a 1-h pulse (see Fig. 4 legend). This is close to the synthesis rates for the viral proteins VP2 and VP3. Thus, the globin mRNA seems to be translated about as efficiently as viral mRNA in infected monkey kidney cells.

Distribution of RNA processing enzymes

Although the ubiquity of the enzymes and factors involved in translation has long been recognised, relatively little is known about the species and cell-type distribution of RNA processing enzymes. Our previous data[12] and experiments presented here establish that monkey kidney cells can both splice and polyadenylate mouse globin RNA. Although we have not characterised the polyadenylation reaction in detail, we believe that the splicing reaction is both specific and efficient. This is indicated by the translation of the resulting mRNA into β^{maj}-globin, and by the failure to observe accumulation of unspliced precursor molecules.

Because mice and monkeys diverged over 70 Myr ago, and because kidney fibroblast cells are not in the erythroid cell lineage, we suspect that the RNA splicing and polyadenylation signals are widely recognised among mammalian species and cell types. Our findings are inconsistent with the notion that the differentiation of a globin-producing cell requires the production of enzymes that specifically process globin and other erythroid mRNAs. On the other hand, the results support the validity of comparing the sequences of globin genes from divergent organisms so as to define the nucleotide sequence specificity of RNA processing enzymes.

SV40 transducing viruses as genetic tools

We have established that a mammalian chromosomal gene can be expressed in a foreign cell after cloning in SV40. The chief difference between this and earlier experiments by Mulligan *et al.*[11] and ourselves[10] using cDNA recombinants is that here expression of the globin gene depends on the mouse genomic signals for RNA splicing and polyadenylation rather than on the corresponding viral signals. Hence, it seems to be a useful substrate for determining the effects of nucleotide sequence alterations on RNA processing. Further, although we have used the SV40 late promoter in this recombinant, it should be possible to bring the globin gene under the control of its own promoter by inverting the mouse fragment relative to the viral vector.

Although cell transformation techniques may also be useful for globin gene transfer experiments (refs 24, 25 and R. Axel, personal communication), there are several advantages of SV40 as a vector for this purpose. First, its small size simplifies localised biochemical mutagenesis. Second, it replicates efficiently, reaching levels up to 100,000 copies per cell late in infection, thus simplifying the detection of gene products encoded by the transduced DNA. Finally, by placing the genomic fragment under the optional control of the strong viral late region promoter, transcription of the inserted DNA can be assured even if its own promoter is not functional. The system's major limitation is that at most 2,500 base pairs of foreign DNA

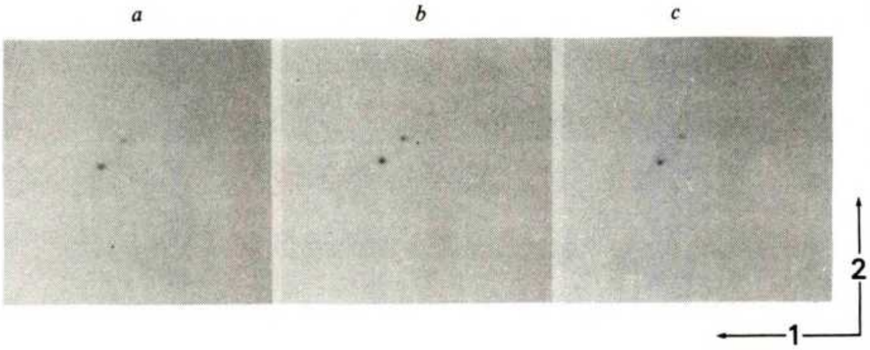

Fig. 5 Fingerprints of tryptic peptides. A 1-ml aliquot of SVβ^{maj}-3-infected cell extract was immunoprecipitated as described in Fig. 4 legend, eluted in SDS sample buffer, mixed with 5 μg of unlabelled mouse globin and electrophoresed through a 20% polyacrylamide-SDS gel. A sample of authentic ^{35}S-methionine-labelled mouse β^{maj}-globin from induced Friend cells was electrophoresed in a separate track. The globin bands were identified by staining, excised, washed with 10% methanol, then digested *in situ* with trypsin-TPCK (Worthington)[21]. The supernatants were lyophilised, resuspended in 25 μl of H_2O and analysed by two-dimensional ascending chromatography on 20 × 20 cm cellulose thin-layer plates (Brinkman). The first solvent was isoamyl alcohol/pyridine/H_2O (90:120:105)[22]. The second solvent was butanol/pyridine/acetic acid/H_2O (32.5:25:5:20) containing 7% (w/v) 2,5-diphenyloxazole[21]. The autoradiographs were exposed for 8 d at −70 °C. *a*, Globin from SVβ^{maj}-3-infected cells; *b*, authentic mouse β^{maj}-globin; *c*, mixture of globin from SVβ^{maj}-infected cells and authentic mouse β^{maj} globin (one-half the amounts used in *a* and *b*).

can be inserted into the late region of the recombinant if it is to be encapsidated into virions. This obstacle might be overcome by propagating the hybrid genome as an episome in persistently infected monkey cells[9], thus overcoming the requirement for encapsidation. Furthermore, it is clear that, although we have concentrated on the globin system, the approach should also be applicable to a variety of other genes.

We thank Drs K. Smith and S. Boyer for anti-β-globin antibody, B. Norman for preparing probes, and Ms C. Harvey for assisting in the preparation of the manuscript.

Rabbit β-globin mRNA production in mouse L cells transformed with cloned rabbit β-globin chromosomal DNA

Ned Mantei, Werner Boll & Charles Weissmann

Institut für Molekularbiologie I, Universität Zürich, 8093 Zürich, Switzerland

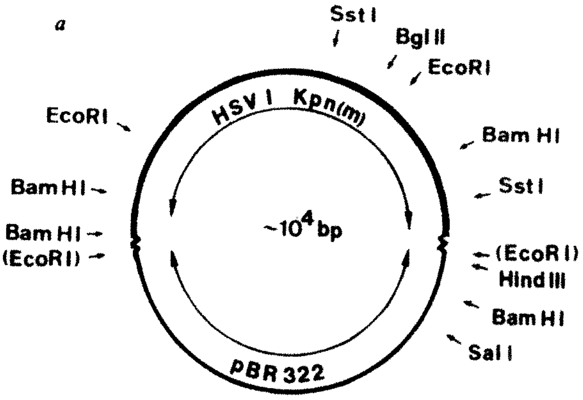
Mouse thymidine kinase-negative L cells were transformed with a cloned rabbit chromosomal β-globin gene linked to the cloned thymidine kinase gene of herpes simplex virus type 1. Most thymidine kinase-positive cell lines contained one or more copies of rabbit β-globin DNA and produced up to 2,000 copies of rabbit β-globin RNA per cell indistinguishable from its authentic counterpart. No mouse β-globin mRNA was detected.

RECOMBINANT DNA technology has made it possible to isolate, amplify and determine the primary structure of any eukaryotic DNA segment of interest. To explore the functional significance of particular regions of a genome, it is desirable to generate localised modifications in the nucleic acid and then evaluate the resulting changes in the biological properties of the genome, *in vitro* or *in vivo* (see ref. 1). The reintroduction of defined nucleic acid segments, in particular of cloned DNA, into eukaryotic cells has been accomplished by various methods. Mechanical microinjection of RNA or DNA into oocytes[2,3] or into somatic cells[4] delivers a large dose of nucleic acid to a relatively small number of identifiable cells. Biophysical and biochemical approaches use liposomes[5,6] or erythrocytes[7] loaded with RNA which are fused with the target cells, or direct treatment of target cells with nucleic acid in the presence of facilitating agents[8–11]. Efficient delivery of DNA to a large population of cells is attained by the use of DNA incorporated into viral particles[12].

0028-0836/79/360040—07$01.00

When a high proportion of the treated cells take up and retain the administered DNA the experiment can be evaluated by assaying the entire cell sample; this is the case when oocytes are individually injected, or when cells are infected with viral particles containing a hybrid SV40 genome. Where the foreign DNA transforms only a minute proportion of the cells, as is the case in most procedures involving administration of exogenous naked DNA, a selection procedure must be used to enrich for transformed cells.

Thymidine kinase-negative cells acquire thymidine kinase activity after transformation with herpes virus DNA, or even better, with an appropriate, purified restriction fragment[9]. As



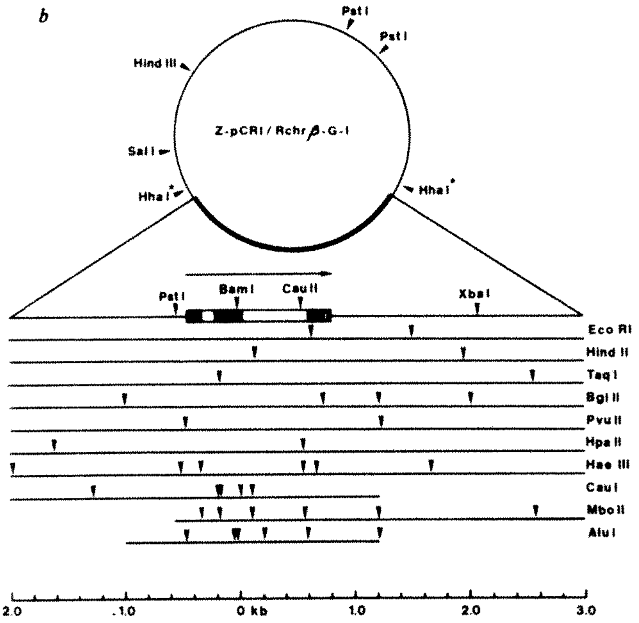


Fig. 1 The restriction map of a hybrid plasmid containing a herpes simplex virus type I DNA fragment with the thymidine kinase gene (*a*) and a rabbit β-globin chromosomal DNA fragment (*b*). The restriction sites of the rabbit β-globin chromosomal DNA hybrid Z-pCRI/RchrβG-1 (ref. 16) were mapped from the single *Bam*HI site by the procedure of Smith and Birnstiel (ref. 42 and A. van Ooyen, J. van den Berg, N.M. and C.W., unpublished results). The thymidine kinase DNA-containing hybrid plasmid Z-pBR322/HSV · TK-M4 was prepared by cleaving herpes simplex virus type 1 DNA with *Kpn*I, elongating the fragments with dAMP and joining them to *Eco*RI-cleaved, TMP-elongated pBR322 (refs 14, 15). Restriction sites were mapped from the single *Bgl*II site by the procedure of Smith and Birnstiel[41] and by total cleavage. The *Eco*RI sites in parentheses are obliterated.

Thymidine kinase-negative mouse L cells (LMTK$^-$) were cultured in Dulbecco's modified Eagle's medium (Flow), 10% calf serum (Eurobio) and 30 μg ml^{-1} bromodeoxyuridine (BUdR). Before transfection the cells were cultured for three doublings in the absence of BUdR, then plated at 4×10^5 cells per 9-cm dish 24 h before DNA addition. TK-gene-containing plasmid DNA was prepared in P-2 containment conditions. To prepare concatenated DNA for transfection, 1.25 μg TK-gene plasmid (Z-pBR322/HSV · TK-P1, -M2 or -M4 (refs 14, 15) and 6.25 μg Z-pCR1/RchrβG-1 (ref. 16) were digested with *Sal*I (New England Biolabs), heated for 10 min at 65°C to inactivate the enzyme, and mixed into a final volume of 0.1 ml with 70 mM Tris-HCl (*p*H 7.2), 10 mM $MgCl_2$, 10 mM dithiothreitol and 1 mM ATP. Ligation was with T_4 DNA ligase for 3 h at 16 °C; no monomeric DNA was detectable by agarose gel electrophoresis. After phenol extraction, ether extraction and ethanol precipitation, the DNA was mixed with 80 μg salmon sperm DNA and used for transfection of five dishes of LMTK$^-$ cells according to the protocol of Wigler *et al.*[17]. Control cells were transfected with *Sal*I-cleaved TK-gene plasmid, without ligation. After 19 days in modified HAT[13] medium (15 μg ml^{-1} hypoxanthine, 1 μg ml^{-1} aminopterin, 5 μg ml^{-1} thymidine in Dulbecco's modified Eagle's medium), colonies were picked with cloning rings and grown up for analysis (see Figs 2, 4 and 5).

* The β-globin DNA content of 10–30 μg of total cell DNA was estimated visually from the autoradiogram of Fig. 2 and additional similar experiments.

† The β-globin RNA content was estimated visually from the autoradiograms of Weaver–Berk–Sharp analyses. Expt 1: the probe used was [5'-^{32}P]-labelled *Bgl*II-cleaved PβG (data not shown). Expt 2: from the experiment of Fig. 4*A*. Calculations are explained in the text. NT, not tested.

only cells possessing thymidine kinase activity can survive and grow in a medium containing hypoxanthine, aminopterin and thymidine (HAT medium)[13], it is possible to select from among 10^6–10^7 cells the few tens or hundreds of cells which were transformed by DNA containing the thymidine kinase gene[9]. We have used this system to select mouse cells transformed with cloned rabbit chromosomal β-globin DNA linked to a cloned herpes simplex virus type 1 (HSVI) DNA fragment containing the thymidine kinase (TK) gene. We find that 19 of 21 cell lines selected in HAT medium contain rabbit β-globin DNA, and 12 of 16 such lines synthesise rabbit β-globin-specific RNA which is indistinguishable from natural β-globin mRNA in all aspects tested.

Transformation of TK$^-$ mouse cells with rabbit β-globin DNA linked to HSVI–TK DNA

We have prepared hybrid plasmids consisting of pBR322 linked to a fragment of HSVI DNA containing the TK gene, either a *Bam*HI (Z-pBR322/HSV · TK-P1) or a *Kpn*I fragment (Z-pBR322/HSV · TK-M2 and Z-pBR322/HSV · TK-M4)[14,15]. Figure 1 shows the restriction maps of the hybrid plasmid Z-pBR322/HSV · TK-M4 (*a*) and of the hybrid Z-pCRI/RchrβG-1 (*b*, abbreviated to RβG), which consists of pCRI linked to a β-globin chromosomal rabbit DNA fragment[16]. The plasmids containing β-globin and thymidine kinase DNA were cleaved at their single *Sal*I sites and joined at a molar ratio of 2.5:1 by T$_4$ DNA ligase to form concatenates. TK$^-$ L cells were transformed with the concatenates (1.5 μg total DNA per 8×10^5 cells) using the calcium phosphate method[8] as described by Wigler *et al.*[17]. Cells transformed in parallel with a *Sal*I-cleaved thymidine kinase plasmid alone served as a control. After 19 days in HAT-containing medium 8–47 colonies per dish were recovered (Table 1). Each of 27 colonies was expanded to about 6×10^7 cells, and DNA and RNA were isolated.

Identification of rabbit β-globin DNA in thymidine kinase-transformed mouse L cells

The DNA from the thymidine kinase-transformed cell lines was cleaved with *Eco*RI and *Pst*I, denatured, subjected to agarose gel electrophoresis and transferred to nitrocellulose filters by the procedure of Southern[18]. As reference, the chromosomal β-globin DNA hybrid RβG, cleaved with the same enzymes, was run in parallel. The filter was hybridised with a ^{32}P-labelled, cloned rabbit β-globin cDNA probe devoid of plasmid sequences[19]. As shown in the restriction map of Fig. 1, cleavage of rabbit chromosomal DNA by *Pst*I and *Eco*RI is expected to yield two β-globin-specific fragments of 1,200 and 900 base pairs, respectively. The autoradiogram (Fig. 2) shows that the four DNA preparations from cells transformed with the rabbit β-globin–TK DNA concatenates had two bands with the same mobilities and the same relative intensities as the 900- and 1,200-base pair bands derived from the β-globin chromosomal plasmid. Altogether, 19 of 21 TK-positive cell lines contained β-globin DNA by this analysis. The control, DNA from cells transformed with a TK plasmid only, did not show these characteristic bands. From the intensities of the bands of *Eco*RI- and *Pst*I-cleaved cell DNA relative to those of known amounts of similarly treated cloned chromosomal DNA run in parallel, we estimate visually that the cell lines P1/R-3, P1/R-4, P1/R-5 and M2/R-1 contain about 3, 8, 1 and 20 copies of rabbit β-globin DNA per cell (Table 1).

Identification and characterisation of rabbit β-globin-specific transcripts from transformed mouse L cells

In vivo transcription of the extraneous rabbit β-globin gene was monitored by a modification of the Berk–Sharp procedure[20] developed by Weaver *et al.*[21], as exemplified in Fig. 3. The hybrid plasmid RβG contains a *Bgl*II site immediately following the 3′-end of the β-globin coding sequence. The hybrid was cleaved with *Bgl*II and labelled with ^{32}P at the 5′-termini. After digestion with *Pst*I, the *Pst*I–*Bgl*II (1,291/1,299) fragment, labelled at the *Bgl*II site (on the (−)strand), was isolated. The labelled DNA was denatured, hybridised with the RNA sample in 80% formamide, treated with nuclease S$_1$ and analysed by polyacrylamide gel electrophoresis in 7 M urea. Only if the labelled 5′-terminus of the DNA is protected by RNA complementary to it is a radioactive fragment recovered. As the probe is labelled on the (−)strand, only (+)strand RNA is detected. Mature rabbit β-globin mRNA protects a fragment about 134 nucleotides long (from the *Bgl*II site to the 3′-end of the large intervening sequence (intron)), whereas a precursor containing both introns would protect about 1,200 nucleotides and a precursor containing only the large intron would protect 929 nucleotides.

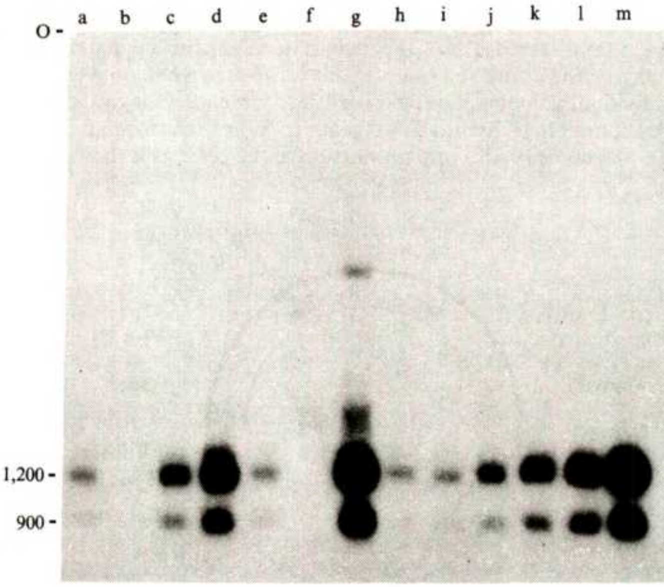

Fig. 2 Detection of chromosomal rabbit β-globin sequences in DNA of transformed mouse L cell lines. Mouse L cell lines transformed with the rabbit β-globin hybrid DNA linked to a thymidine kinase plasmid, or with a thymidine kinase plasmid only, were obtained as described in Table 1 legend. 1.5×10^7 cells were lysed with 1.1% SDS in 0.15 M NaCl and 0.1 M EDTA (*p*H 8), extracted with CHCl$_3$ and isoamyl alcohol (24:1), and the DNA spooled during addition of ethanol to 66%. After treatment with pancreatic RNase, 20 μg ml^{-1} in 10 mM NaCl, 0.5 mM EDTA and 5 mM Tris-HCl (*p*H 7.5) for 8 h at 37 °C, overnight incubation at 37 °C with 100 μg ml^{-1} pronase in 100 mM NaCl, 5 mM EDTA and 50 mM Tris-HCl (*p*H 7.5) and phenol extraction, the DNA was collected by spooling as above. About 300–600 μg of DNA were recovered. Cell DNA (10 μg) was digested with *Pst*I (MRC, Porton) and *Eco*RI (MRC, Porton), denatured and subjected to electrophoresis on a 1.4% agarose gel as described by Jeffreys and Flavell[43]. The DNA was transferred to a 15 × 17 cm Millipore membrane[18] and hybridised to a ^{32}P-labelled rabbit β-globin probe (specific activity, 8×10^7 c.p.m. per μg; about 325 ng in 25 ml) as described[43]. The probe was obtained as follows. The rabbit β-globin cDNA-containing hybrid plasmid PβG[44] was cleaved with nuclease S$_1$ in formamide[45], joined to *Hin*dIII linkers[46] and recloned in the *Hin*dIII site of pBR322 (ref. 19). A hybrid plasmid containing the β-globin sequence present in PβG was identified by nucleotide sequence analysis (Z-pBR322 · H3/RcβG-4.13) and prepared in quantity. After cleaving with *Hin*dIII, the β-globin-specific fragment was purified by agarose gel electrophoresis and nick-translated[47] using [α-^{32}P]-labelled dATP and dCTP (400 Ci mmol^{-1} each; NEN, Dreieich). Autoradiography of the filter was for 30 days. Lanes b and f, DNA from cell lines P1/S-2 and M2/S-2, transformed only with a *Sal*I-cleaved TK-gene plasmid. Lanes c, d, e and g, DNA from cell lines P1/R-3, P1/R-4, P1/R-5 and M2/R-1, transformed with the rabbit β-globin containing hybrid RβG, linked to a TK-gene plasmid. Lanes a and h–m contain as reference RβG digested with *Pst*I and *Eco*RI: 1.6, 1.6, 1.6, 3.2, 6.4, 12.8 and 32 pg of DNA hybridisable to the probe (1.8 pg is the equivalent of one β-globin gene). Lanes a, h and j–m also contain 10 μg of DNA from cell line P1/S-2 digested with *Pst*I and *Eco*RI as carrier. The mobility of the 900- and 1,200-base pair bands is about 1% less in the presence of 10 μg total DNA per slot (compare lanes h and i) than in its absence. O, origin. Ordinate in base pairs.

The probe discriminates between mouse and rabbit globin mRNA because the rabbit mRNA has a *Bgl*II recognition

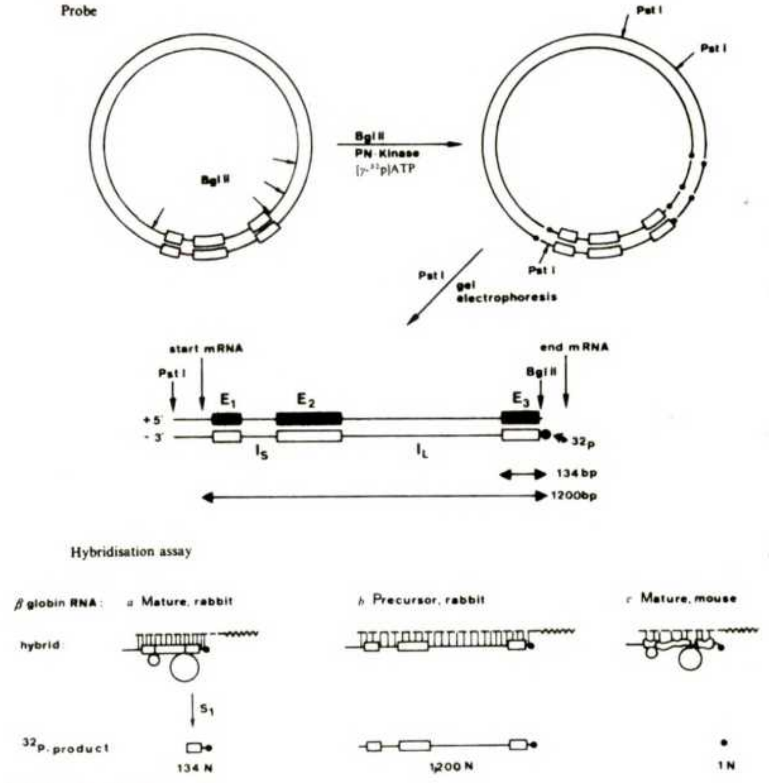

Fig. 3 Application of the Weaver–Berk–Sharp method to distinguish mature and precursor rabbit β-globin mRNA in the possible presence of mouse β-globin mRNA. The procedure is a modification of the method of Berk and Sharp[20]. The probe is a DNA restriction fragment ^{32}P-labelled at one 5'-terminus (rather than being uniformly labelled). The denatured DNA is hybridised to the RNA sample in 80% formamide, digested with S_1 nuclease, denatured and analysed by polyacrylamide gel electrophoresis in 7 M urea. Only if the 5'-terminus of the probe was hybridised to RNA is a labelled DNA fragment recovered. The *Pst–Bgl*II ((+)strand 1,291/(−)strand 1,299 bases) fragment derived from the rabbit chromosomal β-globin plasmid (see Fig. 1), labelled at the *Bgl*II site, is diagnostic for (+)strand β-globin sequences and allows the distinction between rabbit precursor RNA, rabbit mature RNA and mouse RNA. E, exon; I_s and I_L, small and large intron, respectively. PN·Kinase, polynucleotide kinase.

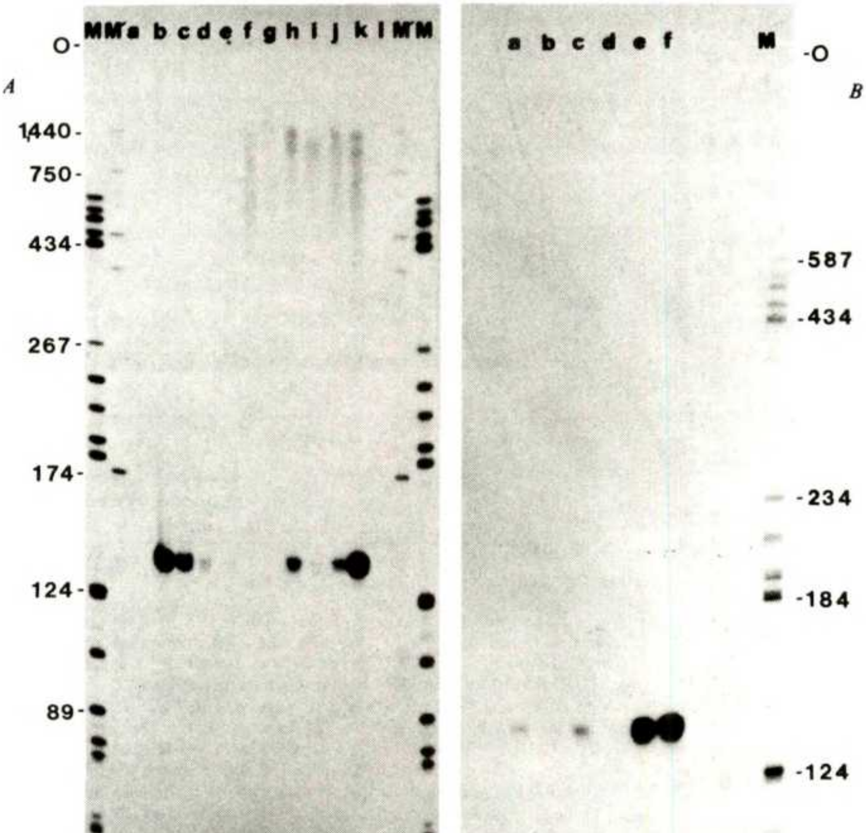

Fig. 4 Detection and characterisation of rabbit β-globin RNA in transformed mouse L cells by the Weaver–Berk–Sharp method. Total cell RNA was prepared from about 10^8 cells as described elsewhere[29]. The yield was about 1.6 mg per 10^8 cells. The ^{32}P-labelled probe (described in Fig. 3) was prepared by cleaving 20 µg Z-pCRI/RchrβG-1 with *Bgl*II (New England Biolabs), treating with bacterial alkaline phosphatase (BAPF, Worthington) and labelling with polynucleotide kinase (P-L Biochemicals) and [γ-^{32}P]ATP (specific activity 3,300 Ci mmol^{-1}, NEN) as described elsewhere[48]. After purification on a Sephadex G-50 column, the DNA was cleaved with *Pst*I (MRC, Porton), and the labelled 1,291–1,299-base pair fragment isolated after electrophoresis through a 1.5% agarose gel and passed through a Chelex column. About 25 ng of probe (13,000 c.p.m.) were denatured by heating in 80% formamide for 15 min at 100 °C and mixed with 50 µg RNA. Hybridisation was carried out in 10 µl of 0.4 M NaCl, 0.04 M PIPES (*p*H 6.4), 0.001 M EDTA and 80% formamide, at 57 °C for 16 h under paraffin oil. The sample was diluted with 100 µl 0.25 M NaCl, 0.03 M sodium acetate (*p*H 4.5) and 0.002 M $ZnSO_4$ and digested with 50 units of S_1 nuclease (purified by the procedure of Wiegand *et al.*[49]). After $CHCl_3$ extraction to remove the paraffin oil, and precipitation with ethanol, the samples were dissolved in 5 µl 90% formamide, 0.05% bromphenol blue and 0.05% xylene cyanol FF, heated for 10 min at 100°C, and analysed by electrophoresis through a 0.1 × 28 × 40 cm 5% polyacrylamide gel (acrylamide : bis-acrylamide, 30:1) in 0.089 M Tris base, 0.089 M boric acid, 2.5 mM EDTA and 7 M urea. Autoradiography was carried out with use of an Ilford Fast Tungstate intensifier screen at −70 °C for 2–5 days. *A*, Unfractionated RNA samples. Lanes a–e, 0, 3, 1, 0.3 and 0.1 ng rabbit globin mRNA ($\alpha + \beta$). Lanes f, g, RNA from cell lines P1/S-1 and P1/S-2, which had been transformed only with a *Sal*I-cleaved TK-gene plasmid. Lanes h–k, RNA from cell lines P1/R-3, P1/R-4, P1/R-5 and M2/R-1, transformed with the rabbit β-globin DNA-containing hybrid linked to a TK-gene plasmid. Lane l, 50 ng mouse globin mRNA. Lanes M, M', [5'-^{32}P]-labelled fragments of plasmid pBR322 as size markers[50]. *B*, Poly(A)$^+$ and poly(A)$^-$ fractions of RNA samples. RNA (50 µg) from cell line M2/R-1 or rabbit globin mRNA (3 ng) was passed through a 0.1 ml oligo(dT) cellulose (type 7, P-L Biochemicals) column in 0.2 M NaCl, 0.01 M EDTA, 0.1% SDS and 0.1 M Tris-HCl (*p*H 7.5)[51]. The column was washed with the same buffer and eluted with H_2O. The RNA in the flow-through and wash (poly(A)$^-$) and in the H_2O eluate (poly(A)$^+$) was precipitated with ethanol. Lanes a, b, poly(A)$^+$ and poly(A)$^-$ fractions of M2/R-1 RNA; lanes c, d, poly(A)$^+$ and poly(A)$^-$ fractions of rabbit globin mRNA. Lanes e, f, 20 and 40 µg unfractionated rabbit bone marrow RNA. Lane M, as above; O, origin. Ordinate in base pairs.

sequence[22] whereas mouse mRNA does not (ref. 23 and N.M., unpublished results), and therefore does not protect the labelled 5′-terminus of the probe. Figure 4*A* shows that as little as 0.1 ng rabbit β-globin mRNA (lane e) gave the expected 134-nucleotide fragment whereas 50 ng mouse globin mRNA (lane l) gave no such band. The RNA from transformed cell lines P1/R-3, P1/R-4, P1/R-5 and M2/R-1 (lanes h–k) yielded as major product the 134-nucleotide fragment. Thus, the majority of globin-specific transcripts are partly or entirely devoid of the large intron. Some weak bands corresponding to fragments of 750–1,200 nucleotides may be due to unprocessed or incompletely processed precursor molecules. RNA from cells transformed with only a thymidine kinase plasmid (lines P1/S-1 and P1/S-2, lanes f and g) gave no detectable bands. From the amount of cell RNA added to the assay (50 μg), the amount of RNA per cell (about 25 pg)[24] and the fact that the intensity of the 134-nucleotide band is similar to that given by 3 ng of total rabbit globin mRNA (about half of which is β-specific), we estimate that cell line M2/R-1 contains about 2,000 rabbit β-globin RNA molecules per cell. By the same criteria, P1/R-3, P1/R-4 and P1/R-5 contain about 600, 50 and 400 β-globin transcripts per cell. As relative band intensities were estimated visually, these values as well as those in Table 1 are only approximate. Altogether, 12 of 16 globin DNA-containing clones had β-globin-specific transcripts (see Table 1).

To determine whether the small intron was present, RNA was hybridised to RβG DNA which had been digested with *Bam*HI, labelled at the 5′-termini and cleaved again with *Bgl*II. After S_1 cleavage and denaturation, polyacrylamide gel electrophoresis revealed a 212-nucleotide fragment, in the case of both authentic rabbit β-globin mRNA and RNA from samples P1/R-3, P1/R-4, P1/R-5 and M2/R-1 (Fig. 5). This shows that the small intron was not present in the transcripts, because otherwise a 480-nucleotide fragment would have appeared.

The 5′-terminus of the β-globin-specific transcripts was mapped by the same procedure as before, using as probe a restriction fragment extending from the *Mbo*II cleavage site at position 129/128 to the *Pst*I site at position −95/−99, [5′-^{32}P]-labelled at the *Mbo*II-cleaved end. As shown in Fig. 6, natural rabbit β-globin mRNA gave rise to a labelled fragment 128 nucleotides long; RNA from the cell line M2/R-1 gave rise to a strong and P1/R-3 to a weaker band in the same position as the β-globin mRNA; in the case of RNA from cell lines P1/R-4 and P1/R-5, only very weak bands were discernible on the original films (but not on the photograph), perhaps because of the relatively low content of β-globin-specific RNA in these cell lines (Table 1). This experiment showed that the only detectable 5′-terminus of the β-globin transcripts mapped in the same position as that of authentic β-globin mRNA; however, we cannot exclude the possibility that a certain proportion of molecules may have a variety of 5′-termini which escaped detection because of a broad distribution of the resulting bands.

The presence of poly(A) on the β-globin-specific transcripts from transformed L cells was demonstrated by fractionating RNA from M2/R-1 on an oligo(dT) column and assaying separately the flow-through fraction [poly(A)$^-$] and the fraction retained at high salt [poly(A)$^+$], using as probe the *Pst*I–*Bgl*II (1,291/1,299) fragment 5′-labelled at the *Bgl*II terminus. About 80% of the β-globin transcript was detected in the poly(A)$^+$ fraction (Fig. 4B).

The mobility of the rabbit β-globin-specific RNA present in the cell line M2/R-1 was compared with that of natural rabbit globin mRNA using the 'Northern transfer' procedure of Alwine *et al.*[25]. The RNAs were subjected to electrophoresis on an agarose gel in denaturing conditions, transferred to diazobenzyloxymethyl paper and hybridised to ^{32}P-labelled rabbit β-globin cDNA[19]. As shown in Fig. 7, poly(A)$^+$ RNA derived from 150 μg of M2/R-1 RNA gave an autoradiographic band with the same mobility and the same intensity as about 8 ng of authentic rabbit globin mRNA; no band was found with the poly(A)$^+$ RNA from 150 μg of RNA from cells transformed with TK DNA only.

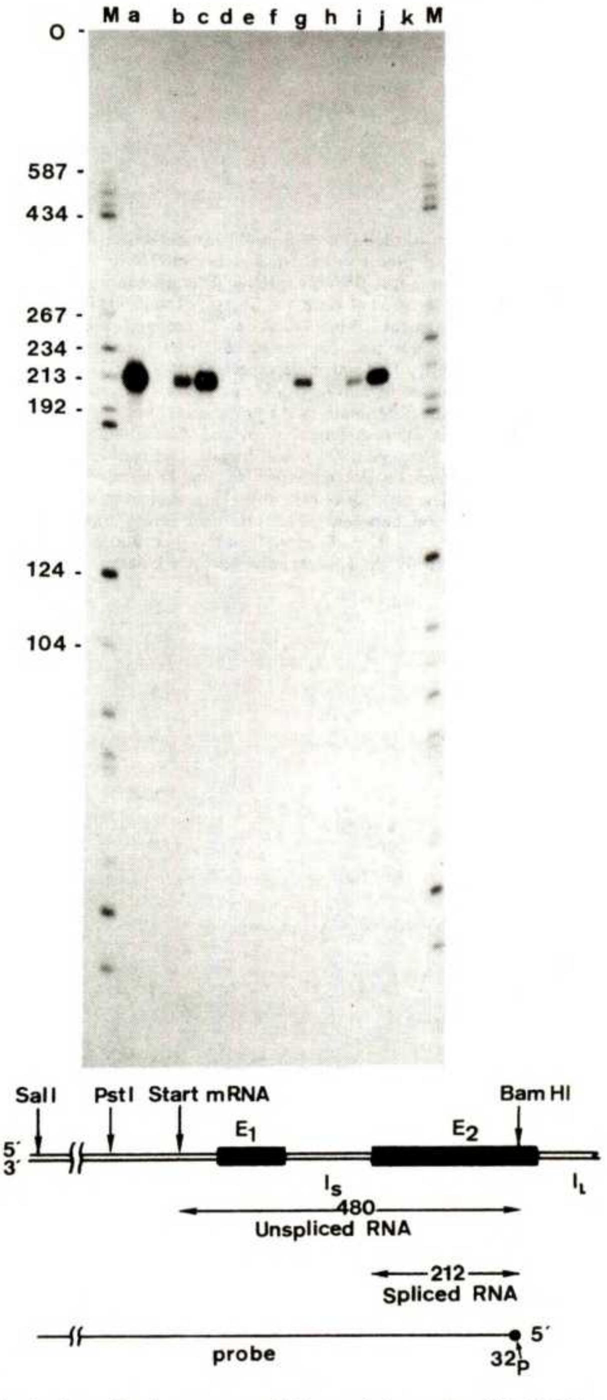

Fig. 5 Assay for the presence of the small intron in rabbit β-globin transcripts from transformed mouse cells. The RNA preparations are those described in Fig. 4 legend. The probe was prepared by digesting Z-pCRI/RchrβG-1 with *Bam*HI, labelling the 5′-terminus with ^{32}P-phosphate (specific activity 2,100 Ci mmole^{-1}) and cleaving with *Bgl*II. Lanes a–c, 3, 0.3 and 1.1 ng rabbit globin RNA ($\alpha+\beta$). Lane d, 50 ng mouse globin RNA. Lanes e, f, RNA from cell lines P1/S-1 and P1/S-2, transformed only with a *Sal*I-cleaved TK-gene plasmid. Lanes g–j, RNA from cell lines P1/R-3, P1/R-4, P1/R-5 and M2/R-1, transformed with the rabbit β-globin DNA-containing hybrid linked to a TK-gene plasmid. Lane k, no RNA. M, Size marker: pBR322 digested with *Bsp*I and [5′-^{32}P]-labelled.

Finally, we determined whether transformed L cells produce mouse β-globin mRNA, in particular when they are synthesising rabbit β-globin mRNA. We again used the Weaver–Berk–Sharp assay, with the [5′-^{32}P]-labelled 123-nucleotide *Bsp*–*Bsp* (−) strand fragment of cloned mouse β-globin cDNA[26] as probe. This (−)strand fragment, which corresponds to the mouse β-globin mRNA segment extending from nucleotide 222 to 344, was purified by hybridising it to mouse β-globin mRNA, isolating the hybrid on an oligo(dT) column and recovering the DNA after alkaline hydrolysis. The assay was carried out as described above; 0.1 ng of mouse β-globin mRNA gave a strong positive signal whereas 10 ng rabbit globin mRNA gave no band, as a sequence complementary to the ^{32}P-labelled terminus of the probe is not present on the rabbit β-globin mRNA. RNA (50 μg total) from L cell lines transformed with TK DNA only (P1/S-1, P1/S-2) or with rabbit β-globin–TK DNA concatenates (P1/R-3, P1/R-4, P1/R-5, M2/R-1) gave no detectable signal (data not shown). From this experiment we estimate that the transformed L cell lines tested, in particular that with 2,000 molecules rabbit β-globin mRNA per cell (M2/R-1), contained less than 50 strands of mouse β-globin mRNA per cell.

Discussion

Concatenates containing a high ratio of β-globin DNA to TK DNA proved to be a convenient device for introducing into mouse L cells multiple β-globin gene copies together with a selective marker which permitted the isolation of transformed cells. Previous experience[27] suggests that the exogenous DNA is largely integrated into host cell sequences, but this point requires further investigation.

Most of the cell lines transformed with rabbit β-globin DNA produced rabbit β-globin-specific RNA. It is striking that the cell line M2/R-1, which contained the highest number of gene copies per cell (about 20), also contained the highest number of RNA molecules (2,000 per cell); however, this correlation did not hold throughout.

The rabbit β-globin-specific RNA of line M2/R-1 was examined in closest detail and was found to be indistinguishable from natural mRNA with regard to its electrophoretic mobility, its 5′-terminus, the absence of the large and small introns and the presence of a 3′-terminal poly(A) tail. The β-globin RNAs of the other cell lines, when tested for one or the other of the criteria, had similar properties.

Synthesis of β-globin mRNA in the mouse occurs through a short-lived 15S precursor[28–32] which represents a complete transcript of the gene, including the introns[33–35]. The same is apparently true for the rabbit β-globin mRNA[36]. It is clear from our results that the splicing enzyme(s) of the mouse cell is capable of acting effectively on the rabbit β-globin transcript. A comparison of the nucleotide sequences of the rabbit and mouse β-globin genes had shown that although the internal sequences of the homologous introns were very different[16,53], the homologous intron–exon junction regions were very similar. The fact that the DNA of SV40, a monkey virus, when injected into *Xenopus* oocytes, leads to the formation of apparently normal SV40 proteins shows that the splicing systems of even widely divergent species are compatible[37]. However, yeast seems to be incapable of splicing the rabbit β-globin transcript[38].

Ziff and Evans[39] have shown that in the case of the adenovirus late mRNA, the cap-carrying 5′-terminus represents the initiation site of transcription. In the case of mouse β-globin RNA the 15S precursor and the mature mRNA have the same 5′-terminal sequence[21] and the same cap structures[26]. If, as we believe, the 15S β-globin precursor is the primary transcript (but for a contrary view, see ref. 31), we may conclude that the rabbit β-globin RNA produced in transformed mouse cells (at least in cell lines P1/R-3 and M2/R-1) originates at the true promoter. We are not certain whether other 5′-termini occur at lower levels, and we cannot yet exclude the possibility that the transcript is initiated upstream at a plasmid or a host promoter, and that the correct, capped 5′-terminus arises by processing. In this connection it is interesting that β-globin transcripts generated in yeast transformed with chromosomal β-globin DNA have 5′-termini which map downstream from the correct 5′-terminus, and 3′-termini mapping within the large intron[38].

No mouse β-globin mRNA was found in TK- or β-globin DNA-transformed mouse L cells used in our experiments (<50 molecules per cell), even when they contained 2,000 rabbit

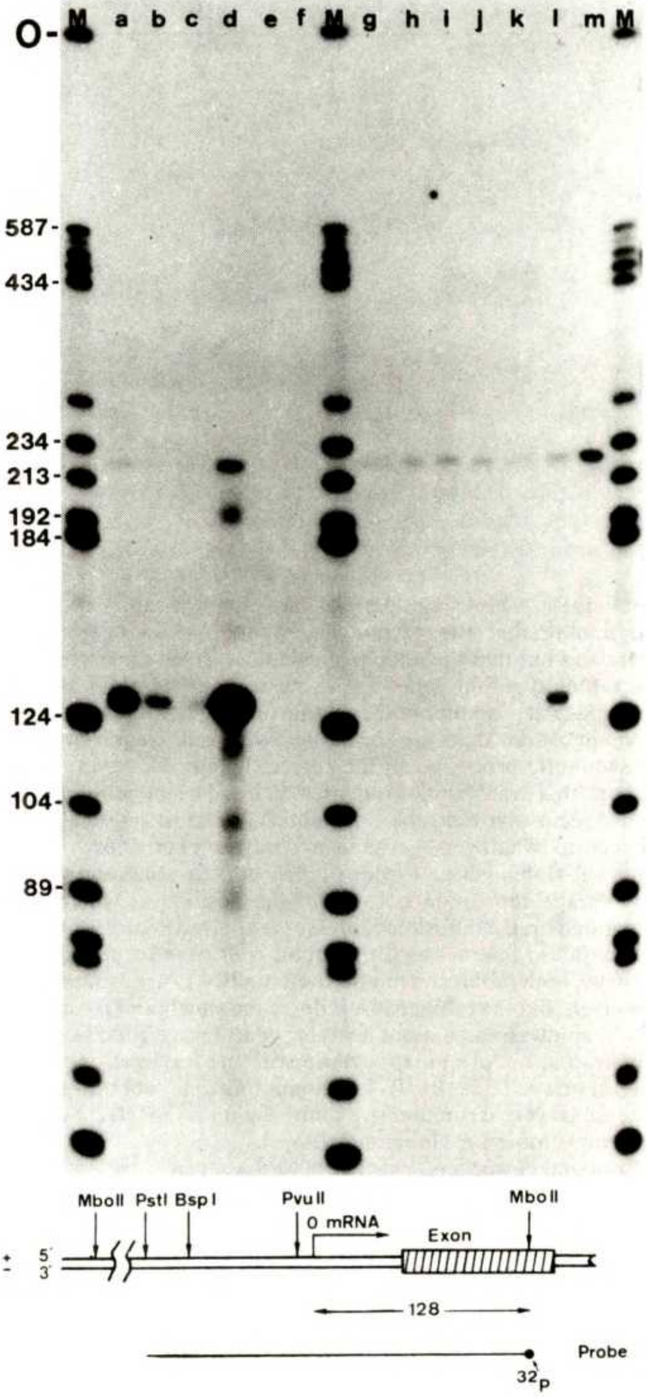

Fig. 6 Mapping of the 5′-terminus of rabbit β-globin-specific transcripts from transformed mouse L cells. The RNA preparations are those described in Fig. 4 legend. The probe for mapping the 5′-end was prepared as follows. Plasmid Z-pCRI/RchrβG-1 was digested with *Hha*I and the largest fragment isolated by centrifugation through a 5–23% sucrose density gradient in a Spinco SW41 rotor, at 30,000 r.p.m. for 12 h at 15 °C. The 6.4-kilobase *Hha*I fragment was cleaved with *Mbo*II (New England Biolabs), and labelled with polynucleotide kinase and [γ-^{32}P]ATP (specific activity, 3,200 Ci mmol^{-1}). After cleavage with *Pst*I, the 223-base pair fragment was isolated by electrophoresis through a 1.6% agarose gel. Lanes a–c, 3, 1 and 0.3 ng rabbit globin mRNA. Lane d, 20 μg rabbit bone marrow RNA. Lane e, no RNA. Lane f, 50 ng mouse globin mRNA. Lanes g, h, RNA from cell lines P1/S-1 and P1/S-2, transformed only with a *Sal*I-cleaved TK-gene plasmid. Lanes i–l, RNA from cell lines P1/R-3, P1/R-4, P1/R-5 and M2/R-1, transformed with the rabbit β-globin DNA-containing hybrid linked to a TK-gene plasmid. Lane m, DNA probe not digested with S_1 nuclease. M, Size marker: pBR322 digested with *Bsp*I and [5′-^{32}P]-labelled.

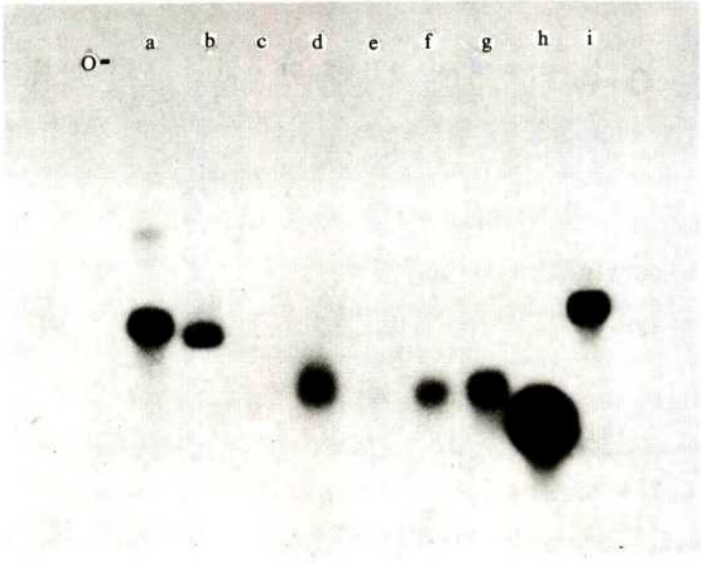

Fig. 7 The electrophoretic mobility of rabbit β-globin transcripts from transformed mouse L cells. Poly(A)$^+$ RNA was prepared as described in Fig. 4 legend. β-Globin mRNA and denatured restriction fragments of rabbit β-globin-specific DNA were used as size markers. All samples (10 μl) were mixed with 40 μl of a mixture consisting of 100 μl 0.1 M sodium phosphate buffer (*p*H 7), 200 μl glyoxal (Merck, Darmstadt; passed three times through BioRad AG-501-X8 CD) and 500 μl dimethyl sulphoxide (Fluka), and heated at 50°C for 60 min[52]. Electrophoresis was through a 14 × 10 × 0.5 cm 1.5% agarose gel in 10 mM sodium phosphate (*p*H 7). The nucleic acid was transferred to diazobenzyloxymethyl paper as described by Alwine *et al.*[25] and hybridised with the ^{32}P-labelled β-globin DNA probe (1.6×10^8 c.p.m. per μg) described in Fig. 2 legend. (a) RβG DNA digested with *Pst*I and *Bgl*II (1,299 base pairs). (b) RβG DNA digested with *Pvu*II and *Bgl*II (1,209 base pairs). (c) Poly(A)$^+$ RNA from 150 μg of P1/S-1 cells (transformed with TK DNA only). (d) Poly(A)$^+$ RNA from 150 μg of M2/R-1 cells (transformed with rabbit β-globin DNA and TK DNA). (e–g) Rabbit β-globin mRNA 1, 4 and 8 ng, respectively. (h) Cloned rabbit β-globin cDNA (*Hin*dIII-cleaved Z-pBR322 · H3/RcβG-4.13, see Fig. 2 legend; ~540 base pairs). (i) RβG cleaved with *Pst*I and *Bgl*II (1,299 base pairs). All samples contained 20 μg yeast RNA as carrier. O, Origin.

globin mRNA molecules per cell. The simplest explanation for the finding that the extraneous rabbit β-globin genes are expressed but that the endogenous mouse genes are not is that the rabbit β-globin genes are being transcribed from a non-physiological promoter (either within or outside the rabbit DNA segment), and that the resulting oversized transcripts are subsequently processed to the correct length. However, if we assume that transcription initiates at the correct promoter, it would seem that the rabbit promoter is at most only partially subject to whatever mechanism controls expression of the mouse β-globin genes: if control is *cis* effective the rabbit gene may escape repression because of the position at which it is integrated or, if a diffusible repressor is operative (*trans* control) it may fail to interact with the rabbit control sequence. Alternatively, both rabbit and mouse β-globin RNAs are produced at low levels, but the rabbit RNA is degraded slowly and the mouse RNA rapidly. Explanations invoking gene dosage effects such as the titrating-out of a putative repressor[40] are less likely, because at least one cell line, P1/R-5, contains only one rabbit β-globin gene and yet accumulates rabbit β-globin mRNA but no detectable mouse β-globin mRNA.

Berg and coworkers[12] have replaced a segment of the SV40 late region by a cloned cDNA copy of rabbit β-globin mRNA. Monkey cells infected by such hybrid DNA underwent a lytic cycle, during which the DNA was greatly amplified. Hybrid mRNA molecules containing the β-globin sequence were transcribed from an SV40 promoter, leading to the accumulation of $>10^4$ hybrid mRNA molecules per cell (P. Berg, personal communication); β-globin was efficiently and accurately translated. We have not yet analysed the proteins produced in our transformed mouse cells, but it seems reasonable to assume that β-globin synthesis, if it occurs, will bear some relationship to the β-globin mRNA content of the cell, and will thus be substantially lower than in the lytic SV40 hybrid system. Thus, thymidine kinase-linked transformation will probably be useful for the study of initiation of transcription and splicing and the SV40 hybrid system for the investigation of translation.

After this manuscript was submitted Wigler *et al.*[41] reported co-transformation of mouse L cells with rabbit β-globin DNA and HSVI–TK DNA.

We thank J. Beggs for carrying out the analysis shown in Fig. 6. This work was supported by the Schweizerische Nationalfonds (No. 3.114.77) and the Kanton of Zürich. LMTK$^-$ cells were obtained from Dr Peter Goldfarb, *Hha*I was from A. Schamböck and rabbit bone marrow RNA from R. Flavell.

Absorption spectrum of the accretion column in VV puppis

N. Visvanathan

VV Puppis is an AM Herculis type binary system exhibiting variable circular and linear polarisation[1]. In its 'normal' state, the optical light curve shows a slow rise to maximum ($m_{max} \sim 15$–16) and a rapid drop to minimum ($m_{min} \sim 17.5$–18) where it remains for ~60% of its 100-min period[2–4]. However, the system has also been observed in faint inactive states[5] ($m_{min} \sim m_{max} \sim 15$). Only a few spectroscopic observations of VV Pup have been published and these show a continuous spectrum with emission lines of hydrogen and helium superimposed. We present here spectrophotometric observations obtained on 2 February 1979. Broad absorption features are seen for the first time in this object in the optical spectrum during the bright phases with high circular polarisation. We suggest that these features be identified with the 6th, 7th and 8th harmonics of cyclotron absorption in a magnetic field of ~3×10^7 G.

The observations were obtained using the image dissector scanner[8] modified as a polarimeter at the $f/15$ Cassegrain focus of the 4-m Anglo-Australian telescope. Full details of the scanner–polarimeter system which is similar to that described by Nordsieck[9] will be given elsewhere.

We obtained 12 scans of VV Pup from 11.48 UT to 14.00 UT with an effective time resolution of 8 min. The spectra cover the wavelength region λλ3,500–7,000 Å and the spectral resolution is ~10 Å. The visual V magnitude calculated from each reduced scan is plotted in Fig. 1 against the phase of VV Pup computed according to Walker's[2] ephemeris. The absolute energy distributions for the bright and faint phases are displayed in Fig. 2. The computed mean (λλ4,000–6,000 Å) value of circular polarisation during the bright phase at 11.58 UT is ~+4.0%, and during the bright phase at 13.40 UT is ~+6.0%.

On the basis of the shape of the optical light curve, (Fig. 1) our observations apparently correspond to an epoch in which VV Pup was in its 'normal' state. However, two important differences should be noted. First, the phase of eclipse ingress differs by $\Delta\phi \sim 0.2$ relative to Walker's ephemeris. This drift in phase is large compared to the maximum drift recorded previously and it could be the result of the period of enhanced mass transfer in March 1978, or a similar event which has occurred more recently. Second, the spectra obtained during the bright phases show broad absorption features covering the spectral regions λλ4,100–4,600, 4,600–5,400, 5,400–6,200, which have not been previously observed.

Variable circular and linear polarisation observed in VV Pup supports a model in which the primary is a strongly magnetic white dwarf rotating synchronously with the binary period[10,11]. In suitable conditions the material from the late type secondary will be channelled towards the magnetic poles where in general a shock ($T \sim 10^8$ K) will form[12,13]. In this model the variable optical radiation originates from a small hot spot at one of the magnetic poles of the white dwarf. The bright epochs with $m_{min} \sim m_{max} \sim 15$ correspond to a situation when the second pole also is active. The faint epochs with $m_{min} \sim m_{max} \sim 18$ occur when both poles are inactive.

In the framework of the above model our observations with $m_{min} \sim 17.8$ and $m_{max} \sim 15.7$–16.5 (see Fig. 1) correspond to an epoch when only the first pole was active. The observed sign of circular polarisation and lack of circular polarisation during minimum phase are consistent with this hypothesis. The absorption features, which are seen only during the bright phases, are probably associated with the gas at the base of the accretion column near the active magnetic pole. From brightness temperature considerations alone, a Zeeman interpretation due to hydrogen at fields $\geqslant 10^8$ G seems unlikely. An attractive possibility is that these features are cyclotron absorption harmonics arising from the accretion column which is believed to dominate the optical radiation.

The wavelength of the mth harmonic for cyclotron absorption by electrons in a magnetic field B (G) is given by $\lambda_m = 1/m\ (10^8/B)$ 10,710 Å. The observed features can thus be identified with the 6th (5,800 Å), 7th (4,977 Å) and 8th (4,380 Å) harmonics with $B = 3.08\times10^7$ G. There is also marginal evidence for the fifth (6,960 Å) harmonic. As the observed features are broad, and do not have well defined cores, there is an uncertainty of 1 harmonic in the above identifications with a corresponding uncertainty of ~20% in B. In principle the detection of lower harmonics in the IR will enable a precise determination of B. However, the comparison star is likely to dominate the spectrum of long wavelengths and the detection of low harmonics may not be possible.

An upper limit to the temperature of the radiating column can be obtained by assuming that the features are broadened by the relativistic Doppler effect.

For a mildly relativistic plasma the half width $\Delta\lambda_m$ of the mth harmonic is given by $\Delta\lambda_m/\lambda_m = m^{1/2}(T/(5.9\times10^9))$ (ref. 14). Using the observed value of $\Delta\lambda_7/\lambda_7$ 0.06, we find $T = 1.3\times10^8$ K. This temperature is consistent with the shock temperature expected for accretion onto a low mass white dwarf[12]. For a column of given temperature and thickness there is a critical value m^* of m above which the column becomes optically thin to cyclotron emission, and the intensity of the cyclotron radiation drops rapidly. The observed turnover of the

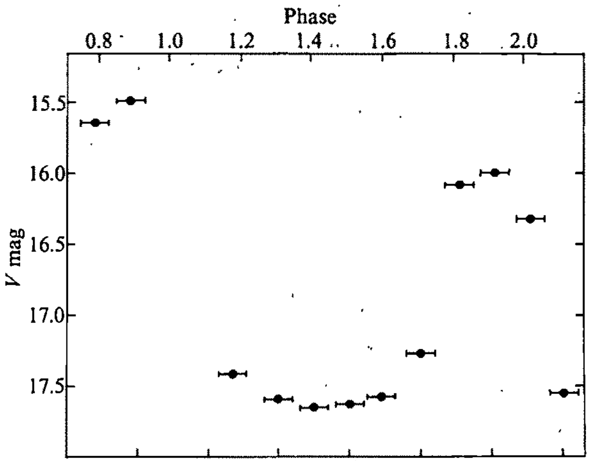

Fig. 1 Light variations for VV Pup during 2 February 1979 from 11.48 UT to 14.00 UT as determined from individual IDS scans with an effective time resolution of 8 min. Phase is given according to Walker's ephemeris.

0028-0836/79/360047—02$01.00

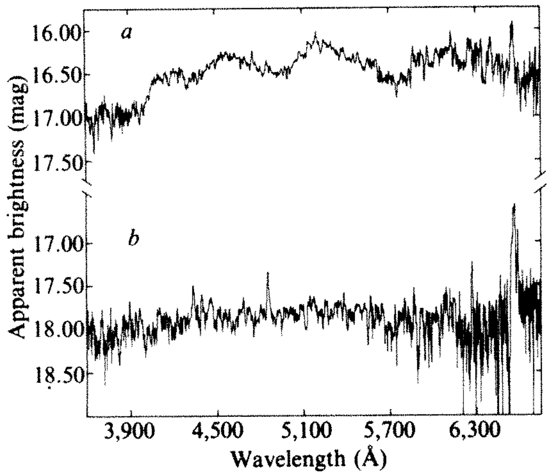

Fig. 2 IDS scans of VV Pup at 10 Å resolution on 2 February 1979 for *a*, the bright (11.48 UT to 11.58 UT) and *b*, the faint (12.27 UT to 13.10 UT) phases.

energy distribution at $\lambda \sim 4{,}100$ Å could then be interpreted as an optical depth effect.

Because X rays have hitherto not been detected in VV Puppis, there is no direct observational evidence, unlike AM Herculis, for the presence of a shock region. It is therefore possible that the features arise from a cooler region and that magnetic broadening effects are important. However, the eclipse data and luminosity criteria favour a high temperature ($\sim 10^8$ K) emitting region of small dimension[5,17].

The absorption features we have observed have not previously been detected in VV Pup. However, the long term variability of the light curve suggests that the height h of the optical column is variable. Values of $10^{-1}R$ and $10^{-2}R$ where R is the radius of the white dwarf, have been reported even at phases when the system had similar maximum brightness[5,6]. It is not clear how changes in the accretion rate are related to the height h, and width d, of the column. For a dipole field geometry and a cylindrical column at a pole a feature of half width $\Delta\lambda$ will survive magnetic broadening if $h/R \leqslant 1/3\ \Delta\lambda/\lambda$ and $d/R \leqslant 8/3\ \Delta\lambda/\lambda$. For the λ4,350 Å feature to be detectable we require $h/R < 0.02$ and $d/R \leqslant 0.16$. A large increase in h or d could easily result in the obliteration of the absorption features by magnetic broadening thus accounting for their non-detection by previous observers.

These spectra of VV Pup show hitherto unreported absorption features which are most probably high harmonic ($m = 6, 7, 8$) cyclotron absorption in the shock region near the surface of the white dwarf.

If this interpretation is correct, this would be the first determination of the magnetic field in the vicinity of a white dwarf in a close binary system. The analogy with Her X-1 where an X-ray cyclotron feature appropriate to the field of a neutron star has been detected is worth noting. Note also that the field strength deduced for VV Puppis lies in the range of field strengths deduced for isolated white dwarfs by the Zeeman effect[16,17].

We thank the AAT Time Allocation Committee for observing time on the 4-m telescope.

Optical counterpart of 2A0311−227

G. Williams, M. Johns, C. Price & A. Hiltner

Department of Astronomy, University of Michigan, Ann Arbor, Michigan 48109

F. Boley, S. Maker & D. Mook

Department of Physics and Astronomy, Dartmouth College, Hanover, New Haven 03755

The X-ray source 2A0311−227 was recently identified independently by Williams[1] and by Griffiths *et al.*[2]. Williams made a tentative identification from an inspection of low dispersion objective prism Schmidt plates taken at Cerro Tololo Inter-American Observatory for the discovery of active galaxies and quasars. The identifying characteristics were strong emission of H and He II. Griffiths *et al.* made the identification from an excellent HEAO-1 position followed by spectroscopic observations. The optical position of the object is α = 3 h 12 min 00.0 s, $\delta = -22° 46' 48''$ (1950). Figure 1 identifies the X-ray source among the neighbouring stars. It has a mag (variable) of about 15. Immediately after the tentative identification by Williams the 1.3-m telescope at McGraw-Hill Observatory on Kitt Peak was scheduled for spectrophotometric observations of the star in question, and we report the results here. A photon-counting spectral scanner was used. The instrument gives a dispersion of 1.15 Å per channel. Exposures of 5 and 10 min were made that covered the spectral region from 4,000 Å to 5,800 Å. A few scans were taken with lower dispersion and broader spectral coverage. The spectrum shows strong emission features, especially H I, He II λ4686 and the C III–N III blend at λ4640–4650 (ref. 2).

Analysis for radial velocities of the individual spectral scans obtained on the first night showed the star to be a spectroscopic binary of short period. Observations on subsequent nights established a period of 81.04 ± 0.01 min (ref. 1).

The velocity curve for Hβ is shown in Fig. 2. The phase was computed from HJD 2,443,915.6300 ± 0.0006 + 0.05628E. The semiamplitude is 355 km s^{-1}. The velocity curve for He II λ4686 is very similar. Any difference in either amplitude or phase is obscured by scatter in the observations. Both Hβ and He II λ4686 show a systemic velocity of +130 km s^{-1}. However, the projection of the solar motion at this galactic longitude and latitude ($l = 212.9$, $b = -57.4$) is 73 km s^{-1} which gives a galactic radial velocity of +57 km s^{-1}. The annual proper motion of $+0.147 \pm 0.013''$ and $-0.070 \pm 0.013''$ in right ascension and declination, respectively (W. J. Luyten, personal communication) indicates that the object is no more than a few hundred parsecs away.

The widths of emission lines are approximately 700 km s^{-1}. Their equivalent widths vary with phase. For example, Hβ changes by a factor of three. However, these equivalent widths must be corrected for variability of the underlying continuum. Preliminary data suggest that variations in the total flux will be small.

Blue and yellow light curves for this object were obtained at Carnegie Southern Observatory (data not shown). There are two maxima and two minima in visual light (5,300 Å); the two minima are of nearly equal depth, but the two maxima differ by 0.4 mag. The total variation is near 1.2 mag, at $V = 13.8$–15.0. A characteristic of the visual light curve seems to be a three-peaked structure at the primary maximum. The separation of the peaks is approximately 6 min and the drop in brightness between peaks is typically 0.3 mag. The central peak, which is also the brightest, occurs at phase 0.775. The maximum is in phase with the maximum velocity of approach. In the blue (4,300 Å) only one maximum is present, which again

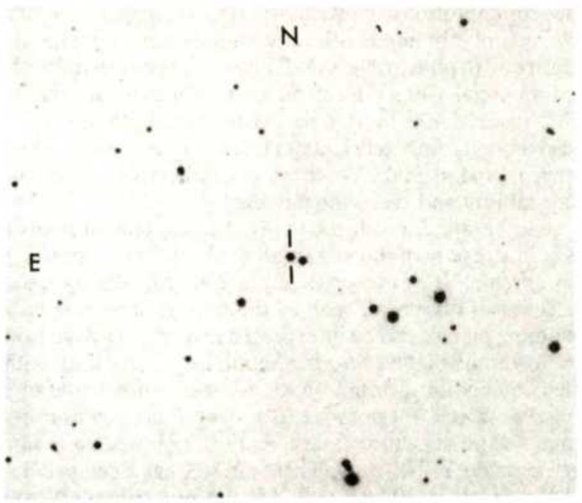

Fig. 1 Identification chart for 2A0311 − 227.

corresponds in phase to the primary maximum of the visual light curve. The total variation in the blue is about 0.6 mag. During one cycle of the blue light curve a large dip of 0.6 mag was observed during the maximum. This dip, which occurred at phase 0.712, had a width at half-minimum of about 2 min compared with 20–25 min for the maximum on which it occurred. One cycle later the dip was again present, although less pronounced. There is a colour variation, as one would expect from the differences in the blue and yellow light curves, with the star reddest at the two maxima of the yellow light curve.

This system has many characteristics in common with AM Herculis. The period is short (81 compared with 186 min), the spectral characteristics are similar (strong H and He II emission), the light curves for both systems are radically different in blue and yellow radiation[3], the two stars show considerable flickering[3] and both stars show variable circular and plane polarisation[4,5]. Each shows a short polarisation pulse that corresponds to maximum light[4,5]. In this system the polarisation pulse occurs at phase 0.742. Interestingly, this agrees very well with the dip in the visual light curve which precedes the central peak of the primary maximum. Finally, both objects have variable X-ray radiation[6,7].

The model for this X-ray source is therefore probably similar to that of AM Her—a white dwarf and a low mass main sequence companion[8]. We suggest a model with a white dwarf of 1.2 solar masses and a companion with 0.2 solar masses. This model follows from the work of Warner who has found that the masses of white dwarfs in cataclysmic variables are typically 1.2 solar masses[9]. He has also found that there is a relationship between the mass ratio and the orbital period. Using this relationship we find a mass of 0.2 solar masses for the secondary. In this model the separation of the two components is 0.7 $R_\odot$ and the main sequence component will just fill its Roche lobe. The collapsed star is most probably a white dwarf, as circular polarisation is observed[5]. Also, this model is compatible with the estimated distance from the proper motion.

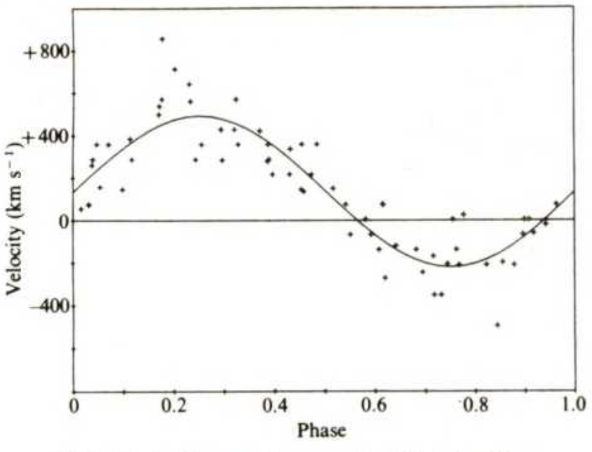

Fig. 2 The Hβ velocity curve for 2A0311 − 227.

The origin of the emission lines is unclear, but, as in other similar systems, they probably arise from the gas flow from the companion to the white dwarf. Further analysis of observational data may assist in establishing a more critical working model for this unique system.

We thank Dr Maarten Schmidt for the opportunity to observe at the Carnegie Southern Observatory, Dr W. J. Luyten for the proper motion, Dr G. MacAlpine for suggesting a search of the available Schmidt plates for high galactic latitude X-ray sources, the Rackham Graduate School of the University of Michigan for support and NASA for support from grant NGR 23-005-464 to the University of Michigan.

Atomic resolution with a 600-kV electron microscope

V. E. Cosslett, R. A. Camps*, W. O. Saxton & David J. Smith*†

Cavendish Laboratory, University of Cambridge

W. C. Nixon, H. Ahmed, C. J. D. Catto, J. R. A. Cleaver†, K. C. A. Smith, A. E. Timbs, P. W. Turner & P. M. Ross‡

Department of Engineering, University of Cambridge, UK

The resolution that may be achieved with an electron microscope can be improved by increasing the accelerating voltage, provided that the electrical and mechanical design is of a sufficiently high standard to realise the theoretical performance[1,2]. Several such microscopes have been constructed in recent years[3–5] and have produced images containing information which can be interpreted directly to a higher resolution than any yet obtained at 100 kV (refs 6, 7). The Cambridge University 600-kV high resolution electron microscope is now yielding high quality micrographs with directly interpretable resolution approaching 0.2 nm. We describe here some of the novel features of this microscope and give some measurements which establish its electron-optical performance. We also show some examples of recent observations which demonstrate the benefits of its atomic resolving power. A more detailed description of the instrument and more references are given elsewhere[2,8].

The electron gun incorporates a lanthanum hexaboride thermionic cathode, in the indirectly-heated rod configuration[9,10]. For operation with a brightness 10 times greater than is normally obtained from a tungsten filament the cathode lifetime is regularly more than 100 h. Such brightness allows observation of images on the fluorescent viewing screen at electron-optical magnifications > ×500,000, and hence permits direct and accurate correction of astigmatism and choice of objective lens defocus without recourse to lengthy trial and error procedures (compare Krivanek *et al.*[11]). Fringes of 0.27 nm spacing from a

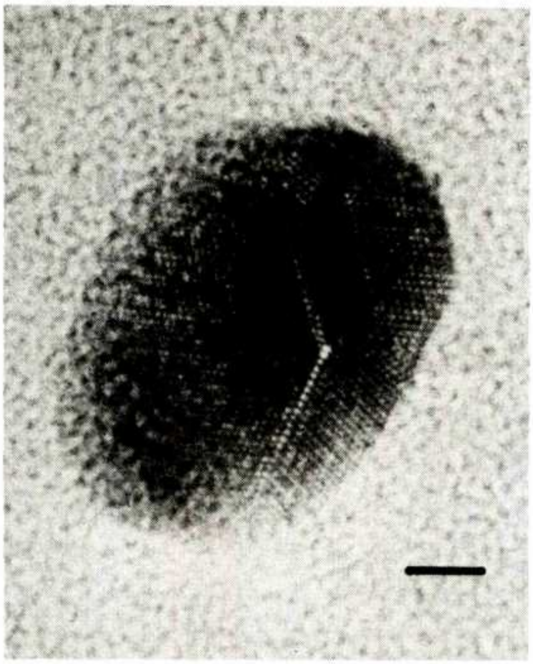

Fig. 1 Micrograph of a small gold particle, supported on an amorphous carbon film, recorded at 575 kV at the optimum defocus. Analysis of the detail in the carbon film defines the imaging conditions and indicates that structure within the particle can be interpreted directly as showing projections of rows of gold atoms separated by 0.235 nm, viewed end-on. Scale bar, 2 nm.

tungsten trioxide specimen have been observed on the fluorescent screen.

The objective lens of the microscope is a symmetrical single-field condenser-objective[12,13], with the specimen located close to the centre of the 14-mm polepiece gap. The calculated spherical aberration coefficient for this lens is 3.3 mm, so that for an accelerating voltage of 600 kV the contrast transfer function of the microscope should have a first zero crossing of 0.20 nm at the optimum defocus. This value provides a useful measure of the information which can be interpreted directly from a single micrograph, although details of finer spacing may be observable at this, and other, defocus values. To ensure that this performance is not degraded by electrical instabilities, highly stable lens current supplies have been developed and the 600-kV generator[14] has been modified to reduce ripple and drift.

The entire electron-optical assembly of the microscope, about 5.5 m high and weighing about 7 tonnes, is suspended from three compressed-air vibration isolation units mounted on the walls of the microscope room. Ambient vibrations have been shown to be attenuated by a factor of the order of 100, to a level at which there is no apparent deterioration of the image quality due to microscope vibrations. A side-loading specimen stage to fit within the polepiece gap (J. H. Lucas, Rickling, Essex) provides x and y tilts of ±30°, and some z motion. The rotational symmetry of optical diffractograms taken from micrographs of amorphous materials indicates that specimen drift is not generally limiting performance. High resolution operation can commence immediately after specimen exchange, which takes less than 3 minutes and uses a locally-produced airlock mechanism.

During the commissioning phase of the construction programme, most operation has been at an accelerating voltage of 500 kV. A recent micrograph of a thin film of amorphous carbon recorded at this operating voltage at the optimum defocus has been analysed using a small local computer system[15]. This analysis showed continuous information transfer, without oscillations in phase, to a resolution of 0.22 nm, indicating that the microscope is indeed capable of providing image details of atomic dimensions. Micrographs can then be interpreted directly to this resolution without recourse to lengthy calculation and prior knowledge of the specimen structure. Details of atomic configurations, particularly in the region of crystal defects, can be obtained without complications in image interpretation due to phase reversals. This is to be contrasted with the best commercial 100 kV electron microscopes where the interpretable resolution is limited to greater than 0.28 nm (ref. 16). Lattice fringes as fine as 0.102 nm have also been recorded with this microscope at 500 kV—these are indicative of the instrumental stability and resolving power.

The micrograph reproduced in Fig. 1 is one of a through-focal series of images which shows a small gold particle supported on a thin carbon film. It was recorded at the optimum defocus, so that image features observed, such as the configurations at each of the twinning planes, can be interpreted in terms of projections of atomic columns. However, it should be noted that without detailed calculations, based on an accurate knowledge of particle thickness, it is not possible to ascribe exact positions to the columns[17]. The structure image in Fig. 2 shows the complex inorganic oxide $Ti_2Nb_{10}O_{29}$. This material has been previously studied in detail at 100 kV (ref. 18) but not apparently at any higher voltage, although the isostructural $Nb_{12}O_{29}$ has been observed at high resolution at an accelerating voltage of 1 MV (ref. 19). The finest specimen features observed at 100 kV in $Ti_2Nb_{10}O_{29}$ which can be interpreted directly in terms of its known structure are the cation positions at the centre of the corner-shared metal–oxygen octahedra which are separated by 0.38 nm. The present image shows much finer interpretable detail, in particular resolving the cations in the edge-sharing octahedra along the regularly-spaced crystallographic shear planes. In a b-axis projection, the centres of these octahedra are separated by only 0.19 nm.

These initial results, and the measured contrast transfer function, indicate that this 600-kV electron microscope has an atomic resolving power, and can be expected to yield substantial and significant information about structures and defects at the

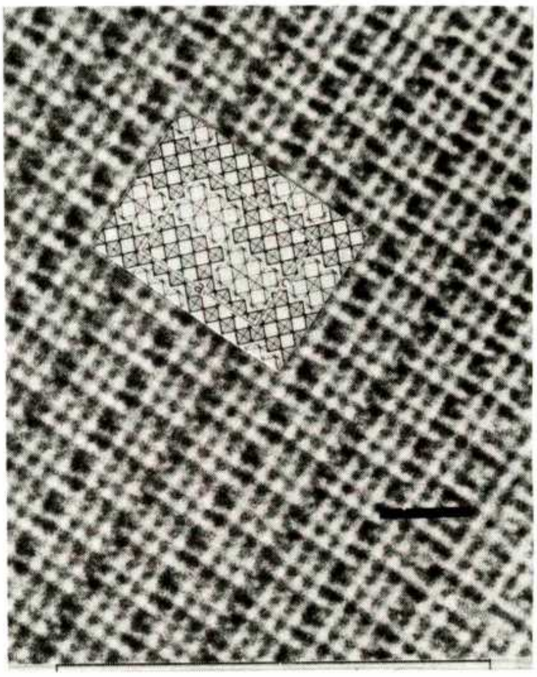

Fig. 2 A structure projection image of the complex inorganic oxide $Ti_2Nb_{10}O_{29}$ in a b-axis projection, recorded at 500 kV at the optimum defocus. As shown in the insert model, this material consists of 3 × 4 blocks of corner-sharing metal–oxygen octahedra, with the central cations separated by 0.38 nm. These blocks, which are at two levels within the unit cell, are joined by edge-sharing octahedra along the regular crystallographic shear planes, with octahedral centres separated by 0.19 nm in this projection. Near the crystal edge, the micrograph can be interpreted directly in terms of this structure although, in thicker regions, a slight misalignment of the crystal is indicated by lack of mirror symmetry. Scale bar, 2 nm.

atomic level for a wide range of amorphous and crystalline materials, covering many scientific disciplines. Applications have already commenced; there is good agreement between calculated and observed images of silicate minerals[20]. Other materials under investigation include amorphous metals, multiply-twinned particles, and intercalated graphite catalysts.

The Cambridge University 600-kV high-resolution electron microscope has been constructed with major financial assistance from the SRC. We thank R. H. Pryor and his staff for their assistance, Drs P. W. Hawkes, M. E. Haine, W. D. Riecke and Mr D. A. S. Rose, and many others, who have contributed to the success of the project, and Dr S. Iijima for providing the $Ti_2Nb_{10}O_{29}$ specimen.

Chemists and mineralogists often have to elucidate the crystal structure of new materials even when conventional X-ray methods are not applicable. If, for example, long-range order is not extensive or the amount of material available for examination is minute ($<10^{-7}$ g) the classical techniques of X-ray or neutron diffraction cannot be used. In such circumstances, direct structural determination using high resolution electron microscopy is, in principle, possible. To achieve worthwhile information, however, a point-to-point resolution of 2.8 Å or better is desirable, if the structural details of most oxides, halides, chalcogenides and various oxysalts of metallic and semi-metallic elements are to be established. We demonstrate here how high voltage, high resolution electron microscopy confirms the structure of a representative silicate mineral, showing the potential of the technique for the elucidation of locally abnormal (at the subunit cell level) structures.

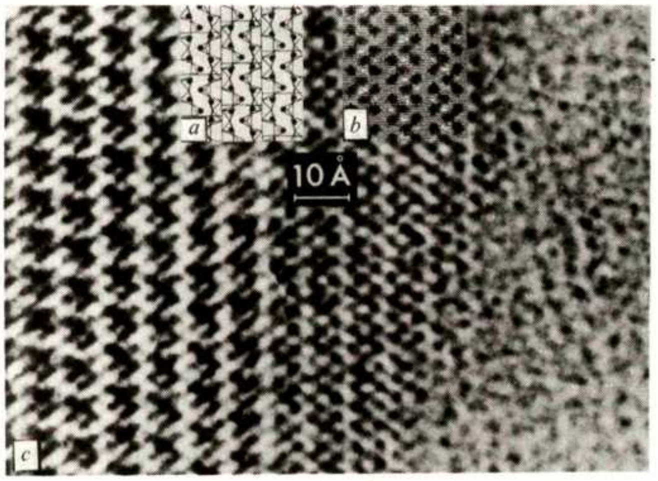

Fig. 1 *a*, Projection down *z*-axis of the idealised structure of wollastonite showing disposition of corner-sharing tetrahedra and Ca^{2+} ions (filled circles). *b*, Computer simulated image (see text and ref. 8). *c*, High resolution micrograph, taken in conditions specified in text.

Currently available 100 kV commercial electron microscopes, fitted with conventional (30°) goniometer stages, cannot structurally resolve (that is, form many-beam images in which each beam has the correct relative phase with respect to the others) interatomic distances of less than ~3.2 Å. (It is, of course, possible to obtain lattice fringes separated by less than 1 Å, but these carry only partial structural information.) Consequently most solid-state chemical work carried out using electron microscopy has until now involved structures based on the linkage of corner-sharing octahedral coordination groups, in which the ion exhibiting the sixfold coordination (for example W or Nb) is largely responsible for the scattering contrast seen in the projected image (of a sufficiently thin specimen). The 'block' and 'shear' structures, where the separation distances of the heavy cations are >3.5 Å are good examples[1–6].

Silicate minerals, which encompass a wide diversity of topologies that arise from various ways of linking SiO_4 tetrahedra, constitute important tests for the methodology of high resolution electron microscopy, principally because there are good reasons for suspecting that hitherto unknown structures can be revealed by direct, real-space examination of minute regions (encompassing some 10^4–10^6 units cells) of naturally occurring materials and their synthetic analogues. Indeed, new topologies (such as multiple-chain structures related to the amphiboles) have recently been identified[7,8] by comparing computed and observed images of ultrathin specimens in various electron-optical conditions. Furthermore, silicates serve as stringent test specimens for high resolution microscopy because: the central tetrahedrally coordinated atom (Si or Al) displays little inherent contrast in comparison to its surrounding atoms, and the inter-silicon distances are significantly smaller (~2.8 Å) than comparable previously imaged distances. Also, the spaces between anionic chains in the silicate network are occupied by cations such as Na^+ and Ca^{2+}, which have scattering powers comparable with those of the atoms in the silicate (or aluminosilicate) macro-anions. Therefore, the interpretation of image contrast is less straightforward and certainly less reliable on an intuitive basis than the contrast displayed by the 'shear' and 'block' structures.

Observations of the pyroxenoid mineral, wollastonite ($CaSiO_3$) have been made with the Cambridge University 600 kV high resolution transmission microscope[9,10]. Micrographs demonstrating its atomic resolving power are shown in the preceding paper[11].

The initial results closely match previously computed[8] images for wollastonite. The structure, as deduced from X-ray work[12] on ordered specimens, consists of infinite one-dimensional chains of corner-sharing SiO_4 tetrahedra (Fig. 1*a*). Si–Si distances within the chains are 3.01 and 3.15 Å, but in projection down the *z*-axis, these reduce to 2.71 and 3.01 Å. Note that in this projection the Ca^{2+} ions which link adjacent chains more or less coincide with the centres of the SiO_4 tetrahedra, and have a separation of 2.9 Å. Computer simulations indicate that a structural resolution of better than 2 Å is required to reveal pairs of chains and the clearly identifiable calcium ions. The computer-simulated image[8] (Fig. 1*b*), in the same projection as Fig. 1*a*, was calculated using the thin phase grating approximation (Δz = 10 Å) with instrumental parameters: accelerating voltage, 600 kV; coefficient of spherical aberration (C_s) 3.3 mm; defocus of 730 Å; and giving a first zero on the phase contrast transfer function of 1.81 Å. The fine structure of the silicate chains is clearly resolved in this simulation, groups of three SiO_4 tetrahedra, and their attendant Ca^{2+} ions, being readily visible.

Results obtained with an actual specimen of wollastonite in the Cambridge microscope can now be compared with the computer simulation. From optical diffraction studies[13,14], we estimate that information in micrographs such as Fig. 1*c* extends to 1.44 Å at the edges of the crystal, where the thin phase grating approximation is observed to hold. This micrograph is from a through-focal series of a wedge-shaped crystal of wollastonite, taken with an accelerating voltage of 500 kV with $C_s \sim 3.5$ mm. The phase grating approximation was observed to be valid within a 50–60 Å region at the periphery of the crystal and within this area the observed arrangement of SiO_4 tetrahedra closely resembles that of the computer simulation.

These results show that the prospects of directly investigating the ultrastructure of a wide range of partially ordered minerals and inorganic solids[2,8,15,16] (borates, phosphates and other classes mentioned earlier) are very encouraging. Such studies of a range of silicates are now in progress.

We thank Drs W. C. Nixon, V. E. Cosslett and their associates[11] for discussions and advice, Dr G. R. Millward and E. L. Smith for technical assistance and the SRC for support.

A projected potential image of a defect in an ordered alloy?

W. M. Stobbs

Department of Metallurgy & Materials Science, Pembroke St,

R. Portier

CECM Laboratoire propre du CNRS, 15 rue Georges Urbain,
94400-Vitry/Seine, France

The high-resolution performance of 100-kV transmission electron microscopes has improved dramatically in the past few years. Use of an objective lens with a spherial aberration coefficient C_s of 0.7 mm and a low incident beam divergence ($\alpha = 0.2$ mrad) allows point-to-point resolutions shown by Bursill and Wood[1] to be ~1.6 Å. These authors, however, distinguish between this 'instrumental' resolution and the resolution which can in principle be used for direct structural resolution and interpretation—only slightly better than 3 Å in the above conditions. The function sin χ, the part of the lens transfer function most directly dependent on the phase changes χ of the electrons as a function of lens defocus and spherical aberration, shows rapid oscillations for spacings smaller than ~2.8 Å even for the optimum defocus condition for which sin χ is apparently −1 over a maximum range of spacings[1]. Thus even if point-to-point resolutions in the 2–3 Å range are obtained, by careful limitation of the beam divergence, the images can only be related to the structure by very careful comparison with computed images. It is this fact and the limited improvement to be expected on any further reduction of C_s, as well as the severe geometric limitations imposed on specimen manipulation in such lenses, which has lead to the approach of using increased accelerating voltages with a concomitant reduction in electron wavelength, λ: the above 'structure resolution' limit is approximately $0.7C_s^{1/4}\lambda^{3/4}$. Most of the high-resolution work to date has concentrated on the examination of materials in which there are strong projected charge distribution periodicities at relatively coarse spacings. To obtain further information on the difficulties involved in the examination of defects in metals (with generally smaller spacings of the important charge projections) we have studied the degree to which images of the ordered alloy Ag_3Mg can be related to naive descriptions of the projected charge distribution.

The Nb_2O_5–WO_3 system is one in which relatively coarse spacings arise. Iijima[2] has obtained particularly beautiful micrographs of this system which are clearly directly interpretable. Other work has been done on silicon and germanium and very good apparent resolutions were obtained by Izui *et al.*[3] on silicon. While the images are very similar to those naively expected for atomic resolution at 1.36 Å along [$\bar{1}$00] in the [110] projection the work of Spence *et al.*[4] and Bursill and Wood[1] suggests that the real instrumental resolution was closer to 1.6 Å, the figure arrived at by the latter authors in their examination of Ti_6O_{11}. This oxide is triclinic and while in the [1$\bar{1}$1] rutile projection discussed by Burstill and Wood[1] the Ti atom column spacing is generally 2.96 Å, near the crystallographic shear planes (CSP) which the material contains at 9.6 Å spacing the projected separation is considerably less. The experimental and computed images are thus of particular interest as the image contrast is complex and shows rapid variation with defocus in a way which is more characteristic of the behaviour to be expected near defects in metals where the symmetry of the local projected potential can be similarly complex.

The minimum spacing of the columns of Mg atoms in the ordered alloy Ag_3Mg (when viewed in the 010 direction (Fig. 1)), is 4.0 Å and thus, given the difference in atomic number

0028-0836/79/360052—03$01.00

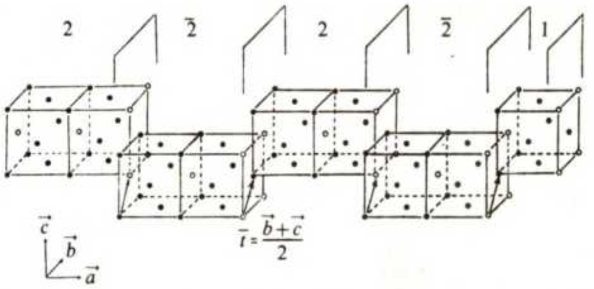

Fig. 1 Diagram, showing the displacements associated with a $(2\bar{2}2\bar{2}1)_2$ long period structure with a repeat in the *a* direction of 72 Å. ●, Ag; ○, Mg.

between Ag and Mg, images showing the characteristics to be expected for the projected charge distribution can be obtained with relative ease. The material also contains periodic antiphase boundaries (PAPB) which have been shown to be strictly planar with 100 normal[5], the translation being $(b+c)/2$. The spacings of the important charge projections at these boundaries as viewed in the 010 direction thus provide an interesting test situation for the appearance of high resolution images. As a function of the degree of stoichiometry the alloy also shows a long period structure apparently controlled, at least over a range of composition, by the atomic ratios[5] with regular insertion of single-cell displacements in a repeat which otherwise shows PAPB every two cells. A diagram of an example of such a structure described, on Fujiwara's[6] notation, as $(2\bar{2}2\bar{2}1)_2$ with a repeat in the *a* direction of 72 Å is shown in Fig. 1. Specimens with structures of this general type show occasional imperfections in the long-period arrays in which the apparent position of the single cell part of the array is displaced (for example, $2\bar{2}1\bar{2}2 \rightarrow 2\bar{2}2\bar{1}2$). In an analysis of the way in which the structure itself arises it is of particular interest to determine whether defects of this type are purely displacive or associated as well with progressive changes in the Mg-to-Ag ratios in the relevant columns. Can this question be answered by examination of images showing characteristics away from the defect as might be expected, on a naive interpretation, in terms of the projected charge density?

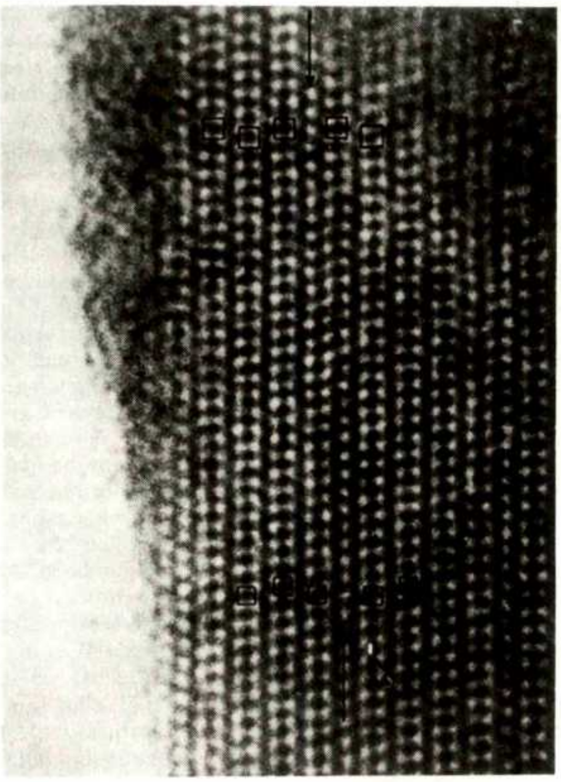

Fig. 2 Axial electron micrograph of a thin region where the position of the single cell width is changed in the long-period structure. The structure is as shown in Fig. 1.

An example of an image of such a defect in the ordered structure is shown in Fig. 2. The micrograph formed part of an extended through focal series. The series was obtained in axial conditions, the specimen being accurately oriented at 010 in a top-entry JEOL tilting holder, in a JEOL 100CX microscope, though with the specimen in a slightly lowered position where Cs is approximately 2.5 mm rather than 3.3 mm as it is for the normally used position in the relatively low resolution pole-pieces of the standard objective lens of this microscope. While a pointed filament was used with a nominal beam current of less than 10 μA and a gun bias sufficient to prevent space charge energy spread limitations in the gun, the images were obtained using overfocussed illumination with $\alpha \simeq 0.5$ m rad. This figure is high and for optimum instrument resolution α should normally be limited to a value less than half this figure: as is well known[7] the envelope function for $\sin \chi$ is controlled not only by the chromatic aberration but also by a combination of the chromatic and spherical aberrations with the convergence and under normal circumstances it is the convergence which is most important.

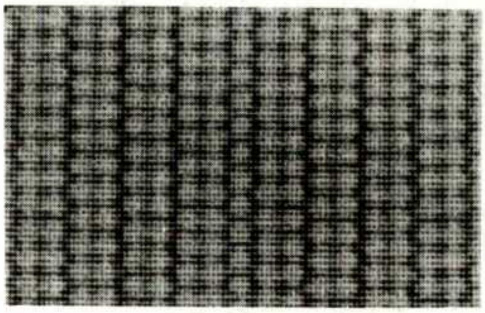

Fig. 3 Image simulation for the model structure shown in Fig. 1 under the experimental conditions used to obtain the micrograph in Fig. 2. C_s, 2.6 mm; Δ_f, 3,040 Å; specimen thickness, 80 Å. A polynomial expansion technique was used and further details of this and other comparative simulations for a variety of thicknesses will be published elsewhere[8].

At first sight the image (Fig. 2) shows features, at least away from the defect, which might be interpreted directly in terms of the projected charge density: the regular $(2\bar{2}2\bar{2}1)_2$ form of the ordering may be clearly visualised. Furthermore in the relevant region the through focal series showed only images of this general type, or ones showing minimal contrast. Further back in the foil a variety of features were observed showing rapid variation with defocus. In fact two other images in the series showed the features characteristic of Fig. 2, both with reversed contrast but with minor differences. Image calculations have been completed which match the observed changes in contrast and an example of such a computation appropriate for comparison with Fig. 2 is presented in Fig. 3. While these calculations will be discussed in more detail elsewhere[8], the simulations and optical diffraction patterns obtained from the contamination at the edge of the foil showed that the three relevant images corresponded to defocus situations at which the 4 Å spacing was optically transferred in the 3rd, 4th and 5th reversals of $\sin \chi$ respectively. The calculations, for an arbitrary but not unreasonable thickness of 80 Å, also demonstrated, however, that the amplitude and phase changes of the various diffracted beams associated with the periodicity of the ordering should have been sufficiently high to make any application of a concept based on the weak phase approximation totally inappropriate. We thus have the intriguing situation that the gross 4 Å periodicity, characteristic of the projected charge distribution, is readily visualised partially because of the relatively high beam convergence reducing the amplitude of the transfer function for the lower spacings readily seen in thicker foils.

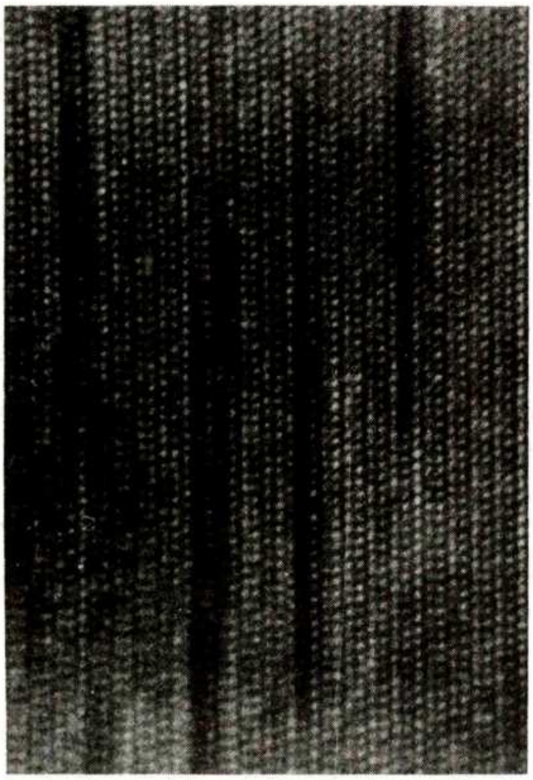

Fig. 4 Axial electron micrograph of a relatively thick region (compare with Fig. 2) at a defocus at which the structure may be visualised. The strong contrast at the defects at this thickness is a clear indication that application of the weak phase approximation would be inappropriate.

Accordingly, although the image in the region of the defect shows none of the features associated with strong diffraction, as are seen in thicker foils (Fig. 4) (see for example ref. 9) and which would normally warn one against any direct interpretation, it is clear that the regular displacements of the apparent projected charge columns near the defect have no simple interpretation. Furthermore the interpretation given here suggests that even with an objective lens with $C_s = 0.7$ mm and low beam convergence no simple interpretation would be possible at the defect not only because the relevant spacings (2 Å) would still lie beyond the first zero in the transfer function but also, and as importantly, because the amplitude and phase changes of the diffracted beams would be too high for the weak phase approximation to be relevant. We have thus demonstrated that in perfect crystals the use of a moderate beam convergence coupled with careful tuning of the transfer function allows images to be produced which, given comparison with computation, bear simple relations to the projected potential despite the main features of the image being transferred well beyond the first zero in the transfer function. That this is so does not, however, allow such an interpretation of a defect and the fundamental question of whether or not the defect is essentially displacive or diffusional will probably be answered only with the advent of a direct structural resolution of 2 Å as may be possible at higher kilovoltages.

This work was partially supported by the SRC and the Royal Society.

High resolution imaging of amorphous materials

W. M. Stobbs

Department of Metallurgy and Materials Science, University of Cambridge, Pembroke Street, Cambridge, UK

David J. Smith

High Resolution Electron Microscope, Department of Engineering, University of Cambridge, Free School Lane, Cambridge, UK

The important role of electron microscopy in the study of amorphous materials is in the examination of the local variation in structure, whether inherent or caused by deformation, irradiation or the nucleation of crystallisation. This requires that the image contain information about local spacings and their variability at the atomic level even if only in relation to a projection. Until recently commercial instruments could not do this for spacings less than about 0.3 nm, and material scientists have either concentrated on the interpretation of coarser structural irregularities in amorphous alloys or used indirect methods to get round the lack of resolving power of the objective lens of their microscopes (see ref. 1 for review). The interpretative dangers of the most obvious approach of using tilted illumination conditions are now well understood[2–5]. While the prospects for dark field interference techniques are a little more promising[6] the essential problem of a nonlinear transfer function remains[7]. More interesting, though with other limitations, is the use of hollow cone illumination[8] with axial transfer[8–11]. Here we present high resolution, axial illumination electron micrographs of such materials with detail at spacings less than 0.2 nm and discuss the difficulties involved in the interpretation of such images.

A JEOL 120CX with a strong objective lens ($C_s = 0.7$ mm) was used to obtain images of amorphous materials in the axial mode showing detail down to 0.17 nm and thus potentially capable of interpretation at the atomic level. This might initially suggest that microscopists should be able to tackle the types of problem mentioned above immediately. However in order to understand how images of, for example, deformation bands may be interpreted it is essential to examine first the extent to which detailed information can be gained on atomic coordination in an 'averagely uniform' amorphous material. Thus, after describing our results, we discuss the extent to which this may be done for the technique used.

The technique of tuning the defocus to show up particular spacings in the image is well known for crystalline objects as is the method of choosing a defocus such that the minimum of the phase change covers a broad band of spacings of interest giving them all phase changes approximating to $(2n+1)\pi/2$. Shifting the 'broad band' transfer interval, in this manner, as the spacing examined gets smaller, becomes increasingly important, particularly because it is here that the transfer is least affected by the beam convergence. We have essentially applied the same arguments to the study of amorphous materials and show that, provided the image resolution is not limited by chromatic aberration, the broad band transfer may be tuned to the spacings of interest for a given material down to spacings of ~0.2 nm.

As examples of images of amorphous materials we show micrographs of phosphorus (Fig. 1) and an FeNiB alloy (Fig. 2). The former image was obtained at 120 kV with a defocus of ~170 nm; the latter, at 100 kV, with a defocus of ~250 nm. The convergence angle of the incident illumination, as suggested by the central spot in the electron diffraction pattern was less than 10^{-3} radians, and a pointed filament was used at a beam current of approximately $8\,\mu$A. The images were recorded at magnifications of approximately 500,000 as calibrated using graphitised carbon test specimens with an error of less than 5%. The optical diffraction pattern of the 120 kV calibration image shown in Fig. 1*b* may be compared directly with that from the phosphorous image in Fig. 1*a*.

It is clear that, in the specified conditions, the optical diffraction pattern of the FeNiB alloy demonstrates transfer down to ~0.2 nm in the amorphous region. The spots in the diffraction pattern (Fig. 2 inset) are associated with the patch of regularly spaced fringes in this particular image area which are at a spacing of approximately 0.19 nm. It is tempting to suggest that the alloy contained some microcrystalline regions in an amorphous sea, or at least increased order, but it also possible that we are seeing the first stages of crystallisation under the beam. The number density of such regions in the electron irradiated area is, however, small and this particular patch was present when the first micrograph was taken which was within 30 s of irradiation. Since crystallisation at the 1.0–2.0 nm level is normally only visible in the conditions used after about 10 min, it is possible that it was present before irradiation. The point of interest is, however, that the first ring in the electron diffraction pattern of this amorphous alloy is centred at a radius of about 5 nm^{-1}. Thus, taking the optical diffraction pattern to be a fair indication, the image of the amorphous region ought to contain information about the local atomic arrangements or at least their projection at this level of resolution. Since the electron diffraction pattern of amorphous phosphorus indicates that there is strong scattering associated with spacings around 0.5–0.6 nm and 0.23 nm the image in this case ought to be even more easily interpreted: at the higher kilovoltage the optical diffraction pattern (Fig. 1*b*) indicates transfer to 0.17 nm.

We must now, however, ask whether or not the optical diffraction pattern is a fair guide to the point to point interpretable information in the micrograph. Consider the appearance of optical diffractograms of axial lattice images. If the crystal is finite, subsidiary maxima appear at 2 g whether or not these fringes are present in the image. Again, even if these fringes are present they can arise through the interference of phase correlated scattering between +g and −g Bragg reflections and thus may not be indicative of transfer at the angles corresponding to 2 g. Lattice fringes with 0.1 nm spacing at the 001 normal of a gold crystal can be obtained axially but this is indicative of transfer corresponding to spacings of 0.2 nm. In the same material the 0.14 nm 220 lattice fringes may be obtained axially at positions away from the normal where only this systematic row of reflections is strongly excited. This does indicate transfer at this inverse spacing. It is, however, well known that this is much easier than demonstrating equivalent transfer for an amorphous material because relatively larger regions scatter coherently in a crystal than in an amorphous specimen.

The most worrying aspect of the points raised above is that the spacings imaged for the amorphous material, as indicated by the optical diffraction pattern, could result from the equivalent of +g: −g interferences as described for a crystal. However, the phosphorous used was <10 nm thick and this explanation does not seem likely. That locally etched regions appear to show structure at lower visibility than elsewhere can also be explained on a solely first order scattering approach. We are comparing transfer function behaviour for a variety of materials as a function of their thickness to get more information on this point, as well as on the extent and lack of zeros in the optical diffraction pattern at the smaller spacings as a function of the convergence employed.

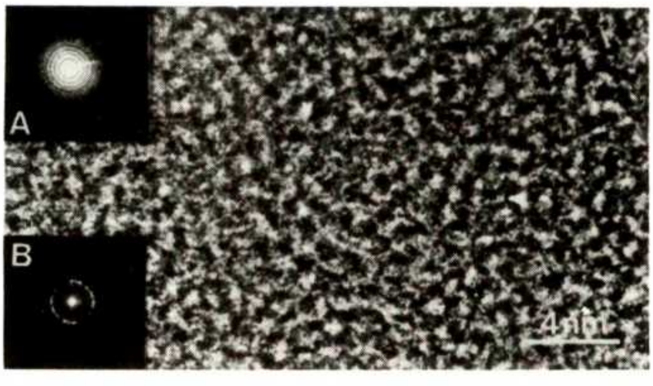

Fig. 1 Image of phosphorus obtained axially at 120 kV. Defocus ~170 nm. Insert *a* is an optical diffractogram showing transfer to approximately 0.17 nm. Insert *b* is from graphitised carbon on the same scale and shows transfer at 0.34, 0.21 and 0.17 nm.

Fig. 2 Image of an FeNiB alloy obtained axially at 100 kV. Defocus ~250 nm. The optical diffractogram shows the transfer of the locally crystalline region at 0.19 nm (the scale is different from Fig. 1).

With the provisos mentioned above, the results described suggest that suitable analysis of a through focal series of images with the deconvolution of the effect of the transfer function should be possible[12], at least down to spacings at which the ring structure of the transfer function may be seen in the optical diffractograms (~0.2 nm). While recording the images requires some care in using a relatively low beam current, the low C_c of the objective lens of the JEOL 120CX means that under normal circumstances the most important experimental aspects are to keep a low beam convergence and to tune the broad band of the transfer function to the spacings of interest.

Note that images of the type described here, where the relevant resolution is attained at relatively large values of defocus, and concommitantly chopped transfer, require considerable computational analysis before a full projection of the amorphous structure may be visualised. (It is extremely difficult to do this without recourse to the weak phase approximation and it is becoming increasingly obvious[13,14] that this is not very realistic even for the extremely thin specimens normally examined (<10 nm) unless they are of low atomic number.) If the weak phase approximation is not valid then the computation of the relation between the projected structure and the image is much easier if there is continuous transfer out to the lower spacings of interest for the given specimen. This can be done most easily by increasing the accelerating voltage.

We thank H. Wendt and P. Extance for specimens and the SRC and the Royal Society for the provision of facilities and for financial support (to D.J.S.). We are also grateful to D. Ackland for the maintenance of the microscope.

Wetting, drying and permeation processes in various porous materials are of special interest to soil science and agriculture, building science and chemical engineering. Direct experimental study of unsaturated flow within such materials is hampered by the difficulty of detecting with precision changes in their internal water content distributions. In laboratory work on soils gravimetric sampling is widely used[1]. However, this is a destructive method which interferes with water flow processes and in any case is not easy to apply accurately to rigid materials such as permeable rocks, ceramics and building materials. γ-ray attenuation is the only established non-destructive instrumental method in laboratory use[2,3]. We report the first use of a nuclear magnetic resonance (NMR) imaging technique to monitor the dynamics of the internal water content distribution in several porous inorganic materials during capillary inflow.

The NMR imaging technique allows NMR signals to be isolated selectively from individual volume elements within a structure containing NMR-active nuclei. The major aim of work on this technique is to develop an imaging method for use in medical diagnosis, complementary to existing methods such as X-ray tomography. A description of our method of NMR image formation and examples of its medical use have been given elsewhere[4–6]. However, the technique is applicable to the study of the distribution of nuclear density within any non-metallic material. In the present case, the hydrogen nuclei (protons) of mobile water molecules within the pores of the material give rise to the NMR signal of amplitude proportional to the water content in defined volume elements.

Our apparatus uses an iron-cored electromagnet generating a field of 0.7 T, corresponding to a proton resonance frequency of 30 MHz. The magnet has a horizontal cylindrical sample compartment of diameter 80 mm and length 600 mm. This configuration is well suited to the study of the movement of the wetting profile during horizontal capillary absorption of water into long rectangular specimens with sealed sides (approximating to one-dimensional absorption into a semi-infinite solid). Subsequently redistribution and drying processes may be observed.

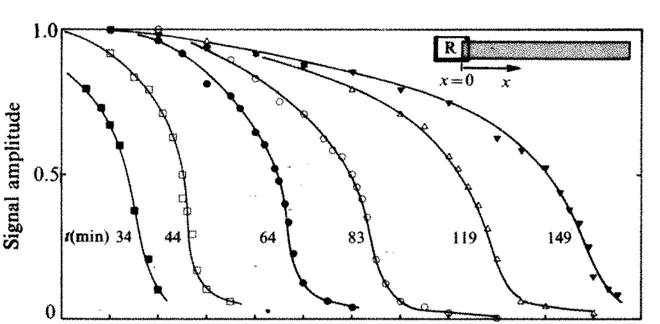

Fig. 1 Water content profiles obtained by NMR during capillary absorption of water by a plaster bar. Elapsed times t are shown. The bar (235 × 33 × 33 mm) was cast from a mix (1 : 2 by volume) of a commercial hydrated lime and a commercial retarded hemihydrate plaster (class B, type b2 gypsum building plaster). After setting and drying, all side faces were sealed with an epoxy coating. Inset sketch shows bar with attached reservoir R to supply water to the inflow face during the experiment. Signal amplitude is scaled to the range 0–1, corresponding to a reduced water content (θ) range of 0–1. $u_1 \sim 0.45$ cm^3 water per cm^3 dry solid.

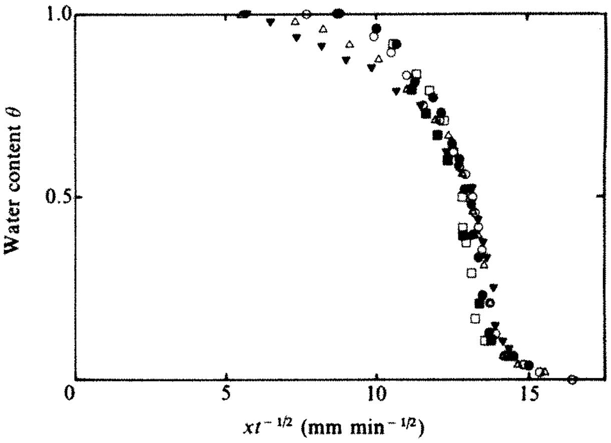

Fig. 2 Water content profiles of Fig. 1 replotted against $xt^{-1/2}$ ($= \phi$) to form a θ–ϕ master curve.

The NMR signal was collected from a magnetically defined thin slice of the specimen transverse to the direction of flow. The complete water content profile was obtained point by point by stepping the specimen in the direction x through the defined slice, enabling the water content in the slice to be determined at a number of distances from the inflow face ($x = 0$). The time needed to measure the NMR signal amplitude from each slice was about 10 s; thus a complete profile could be obtained in about 5 min. Figure 1 shows a family of water content profiles determined during capillary absorption into a gypsum-lime plaster bar. The signal amplitude is scaled to correspond to the range 0–1 in θ, the reduced water content. ($\theta = (u - u_0)/(u_1 - u_0)$ where u is the volumetric or gravimetric water content and subscripts 1 and 0 indicate nominal saturated and dry states[7]. All materials used were initially air-dry; thus $u_0 \approx 0$ and $\theta = u/u_1$.) The shape of the leading portion of the profile (at the lowest water contents) is sensitive to the defined slice thickness. Subsequent measurements showed a steeper intersection with the x axis (see Fig. 3), and a resolution of <2 mm.

Much of the analysis of unsaturated flow developed in soil physics[8] and more recently applied to water transport in building materials[7,9] is based on the extended Darcy equation[10]. If valid, this means that one-dimensional horizontal flow is described by

the nonlinear diffusion equation

$$\frac{\partial\theta}{\partial t}=\frac{\partial}{\partial x}\left\{D(\theta)\frac{\partial\theta}{\partial x}\right\}$$

where θ is the water content and D is the unsaturated hydraulic diffusivity, a property of the porous material. This equation has the solution $x(\theta, t) = \phi(\theta)t^{1/2}$ for absorption at a wet face ($\theta = 1$) into an initially dry ($\theta = 0$) semi-infinite homogeneous material. Thus the water-content distance profile advances as $t^{1/2}$, maintaining constant shape $\phi(\theta)$. Figure 2 shows that the profiles of Fig. 1 when replotted against $xt^{-1/2}$ fall approximately on a single θ–ϕ master curve. Figure 3 shows similar master curves obtained from capillary inflow profiles on three other materials.

These results, taken together with the reworking (unpublished) of two sets of γ-ray data[11,12] on autoclaved aerated concretes and with a number of studies on soils[13] provide strong support for the applicability of the extended Darcy equation to such porous materials. From θ–ϕ data the unsaturated diffusivity $D(\theta)$ may be calculated for each material by the method of Bruce and Klute[14]. Results for six materials are shown in Fig. 4.

Several other wetted porous materials have also been examined. Apparently satisfactory signals were obtained from a clay loam, and from two sand samples. The NMR response from several specimens of fired-clay building bricks and from an autoclaved aerated concrete was extremely weak, indicating an exceptionally short nuclear relaxation time. A calcitic sandstone also gave a very weak response. The factors controlling signal amplitude from different materials have not been investigated.

We thank Professor E. R. Andrew for his interest and encouragement. We acknowledge the support of the SRC (UMIST) and MRC (University of Nottingham).

Single colloidal crystals

Noel A. Clark & Alan J. Hurd

Department of Physics and Astrophysics, University of Colorado, Boulder, Colorado 80309

Bruce J. Ackerson

Department of Physics, Oklahoma State University, Stillwater, Oklahoma 74074

Colloidal suspensions of highly charged, monodisperse polymer spheres exhibit long-range (crystalline) translational ordering in appropriate conditions of charge, number density, counterion concentration and temperature[1–5]. These 'colloidal crystals', which can conveniently be made to have lattice parameters comparable to or greater than optical wavelengths, offer unique opportunities for the study of the collective static and dynamic behaviour of strongly interacting spherical particles. For example, such systems may readily be probed by relatively simple but powerful light scattering spectroscopic techniques[6,7]. Furthermore, the ordering itself offers intrinsic advantages, both experimental (for example, fluctuations normally observable only about the k-space origin appear about Bragg spots, with reduced stray light and multiple scattering effects), and theoretical (the simplicity of calculating on the basis of a known rather than only statistically defined structure is well appreciated from experience with atomic solids and liquids). To exploit these ordered structures fully, reliable methods of producing orientated single crystals suitable for light scattering and other optical studies must be developed. For light scattering from bulk samples the primary requirement is that the ratio of interparticle spacing to diameter, a/d, be sufficiently large. This reduces interference by multiple scattering and renders the particle scattering factor nearly constant through those scattering angles [$|k| < (2 \rightarrow 5)2\pi/a$] where the most useful information concerning crystal structure and dynamics appears. We now describe a technique whereby single body-centred cubic (b.c.c.) colloidal crystals, well suited for light scattering and having particular orientations, may be produced.

Our method is shown schematically in Fig. 1, and may be described as follows. The colloidal suspension (0.109 or 0.234 μm diameter Dow polystyrene spheres at ~0.1 wt% in thoroughly deionised water) is introduced into a rectangular quartz cell of path length 1 or 2 mm (Fig. 1*B*). A shear flow is created by mechanically rocking the cell about the axis normal to the flat quartz plates which form the faces of the cell. The intensity distribution of light scattered by the spheres in suspension from a weakly focused argon ion laser is observed and photographed on a translucent screen. At zero flow rate the suspension, if suitably deionised, will crystallise. The application of shear flow disrupts the crystallisation such that suspensions which are crystalline at low or zero shear rates adopt a liquid-like, amorphous structure at sufficiently high shear rates (≳20 Hz). Figure 2*A* shows the scattered light intensity distribution from a suspension under shear and it exhibits the diffuse Debye–Scherrer ring typically observed in the static structure factor of liquids of strongly interacting spherical particles. If the shear flow is stopped abruptly (within 1 s), crystallisation begins immediately, with the nucleation of crystallites at a large number of (as yet unidentified) sites in the suspension which grow to fill the entire suspension volume in a few minutes. The result is a polycrystalline array yielding a scattered light intensity distribution typical of crystalline powders (Fig. 2*B*). Such arrays seem to be stable over periods of several months.

If, on the other hand, the shear rate is only very gradually decreased to zero (over a period of ~10^3 s), the resulting structure is much more highly ordered, as indicated by its diffraction

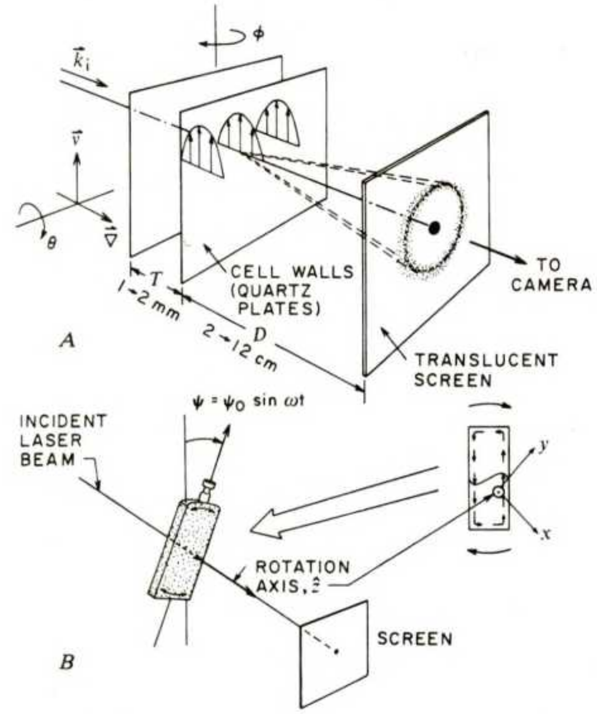

Fig. 1 *A*, Geometry of the apparatus for the generation and observation of b.c.c. single crystals. *B*, Details of the sample cell. Samples were placed in quartz cuvettes of dimension 1 or 2 mm × 5 mm × 10 mm, with a small amount of mixed bed H-OH ion-exchange resin in the bottom. Variable shear flow was induced by rocking the cell about the z axis ($\psi \cong \psi_0 \sin \omega t$) at a variable frequency ω. Inertia of the suspension produced the indicated flow pattern relative to the cell, with $\vec{v} \perp \hat{z}$ in the probed region and with the largest velocity gradient having $\vec{\nabla}| |\hat{z}$. The $\hat{x}$ and $\hat{y}$ axes in the inset are shown in one of three possible orientations, the $\hat{x}$ axis of crystals making angles of 0°, 60° and 120° to $\vec{v}$.

pattern (Figs 2*C*, 3*A*). The study of this pattern and its dependence on the cell orientation angles (θ, φ, Fig. 1*A*) indicates that this structure is an array of two-dimensional hexagonal closest packed (h.c.p.) layers orientated normal to the velocity gradient (z axis, that is, parallel to the quartz plates) and with a set of two-dimensional h.c.p. rows of index 10 parallel to the velocity vector. We believe the stacking of these h.c.p. layers to be nearly random as, on the one hand none of the Bragg spots in the two-dimensional h.c.p. pattern is eliminated by this stacking, but on the other hand the two-dimensional h.c.p. 30 spots are generally of comparable intensity to the others, indicating the lack of registration of the two-dimensional h.c.p. planes in discrete three-dimensional h.c.p. sites. The formation of this and other structures of intermediate order from the liquid as the shear rate is lowered will be discussed elsewhere.

This disordered array of two-dimensional h.c.p. layers is a metastable structure. Within several hours of its formation a new structure appears at sparsely scattered nucleation sites and slowly grows over a period of days to weeks to fill the suspension volume. Figure 3*B* shows a typical diffraction pattern obtained from this second structure with the cell normal to the incident laser beam (θ. $\varphi = 0$). We identify the second structure as a single crystal orientated as indicated in Fig. 4*A*, with a set of planes containing a 110 and a 100 axis parallel to the two-dimensional h.c.p. planes of the metastable structure and therefore parallel to the bounding plates. The b.c.c. structure has been observed previously in low-density colloidal crystals[5]. The nucleation process is such that the b.c.c. 110 axis is parallel to one of the three two-dimensional h.c.p. 10 axes, allowing three distinct orientations of the b.c.c. crystals about the z axis. The b.c.c. crystals, once nucleated, grow most rapidly along the z axis to fill the space between the plates and then gradually expand in the plane of the cell, with large crystals growing at the expense of smaller crystallites. The result, after several days to weeks, is a mosaic of single b.c.c. crystals, each completely filling the millimetre-size gap between the cell walls, and having one of the three preferred orientations about z. In a sample left undisturbed for 2 months after preparation of the h.c.p. structure single b.c.c. crystals as large as 7 mm × 5 mm × 1 mm were found.

Figure 4 *A* shows the b.c.c. crystal orientation which produces the intensity distribution of Fig. 3*B* along with the corresponding f.c.c. reciprocal lattice and Ewald sphere for our light scattering geometry with the sample cell normal to the laser beam (θ, $\varphi = 0$). By suitably rotating the sample about the x and y axes some 16 reciprocal lattice points can be brought onto the Ewald sphere to produce Bragg scattering. Figure 3*C* shows typical results. Here the cell has been rotated about two axes ($\theta = -8.1°$, $\varphi = -11.5°$) to bring the 011, 211 and 200 points onto the Ewald sphere ($2\pi/k_i = (\lambda/n)i = 458$ nm$/1.33 =$ 344 nm). Note the complete absence of 111 and 100 spots, which disappear in b.c.c. diffraction patterns, whereas the observable Bragg reflections index to within a few per cent of those expected for a b.c.c. lattice. Typical cubic lattice parameters were $a = 2.2$ μm, about 10 particle diameters.

The geometry of Fig. 4*B* indicates that there is no Bragg scattering with the cell normal to the incident beam, so that the intensity distribution of Fig. 3*B* must arise from displacements of spheres from their positions in a perfect b.c.c. lattice. Visual inspection of this light shows a pattern of fluctuating coherence areas indicating that it is dynamic in character. Preliminary intensity fluctuation spectroscopy studies show a characteristic fluctuation time which increases as the intensity increases, such as when a Bragg reflection is approached. These observations, along with the similarity of the observed intensity distribution to that for X-ray thermal diffuse scattering in the same planes of atomic b.c.c. crystals[8], lead us to identify this non-Bragg scattering tentatively as thermal diffuse scattering, that is, arising from thermal vibrations of the b.c.c. lattice.

The quality of the b.c.c. single crystals was evaluated by (1) monitoring the presence or absence of spurious Bragg spots; (2) monitoring the spatial distribution of the Bragg reflected light; (3) by the presence of Kossel lines. The b.c.c. crystals, once formed, were extremely delicate. Motion of the cell would invariably lead to distortion and shrinkage of the crystals. Damage produced by motion of the cell, if not too extreme, would anneal out over a period of a few days. In carefully handled samples diffraction-limited Bragg spots from crystals of size ~1 mm³ could be readily obtained.

In well ordered samples the diffraction pattern exhibited Kossel lines (Fig. 3*D*). These are light (dark) bands in the diffusely scattered light where rays have been Bragg reflected into (away from) directions corresponding to the Bragg angle for a set of crystal planes. The diffusely scattered light is incident at

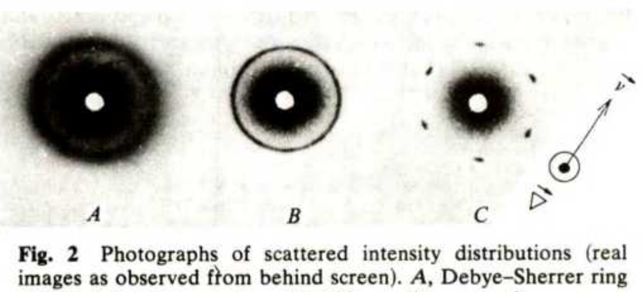

Fig. 2 Photographs of scattered intensity distributions (real images as observed from behind screen). *A*, Debye–Sherrer ring obtained for a suspension of 0.109 μm-diameter spheres translationally disordered by shear at a root mean square shear rate of 20 Hz: (θ, $\varphi = 0$). This suspension is crystalline at zero shear. $T = 1$ mm, $D = 2$ cm. *B*, Crystal powder pattern obtained from the suspension of *A* if the shear is abruptly stopped; (θ, $\varphi = 0$). Intensity distribution obtained from suspension of *A* if the shear rate is gradually lowered to zero. The shear velocity and gradient directions are indicated. The structure is a disordered array of two-dimensional h.c.p. layers with the two-dimensional h.c.p. planes normal to $\vec{\nabla}$ and having a 10 direction normal to $\vec{v}$ (θ, $\varphi = 0$). $T = 1$ mm, $D = 12$ cm.

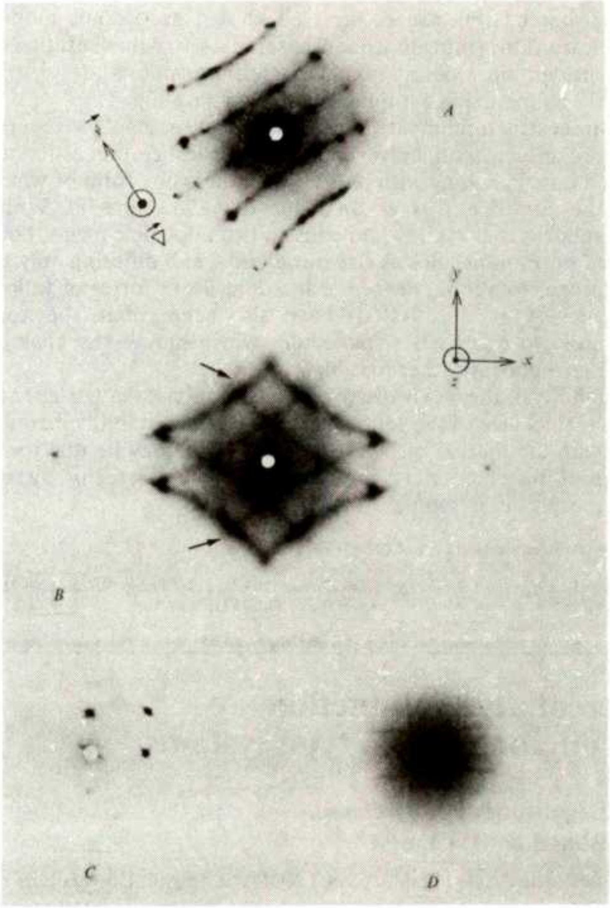

Fig. 3 Photographs of scattered intensity distributions (real images as observed from behind screen). *A* Same as Fig. 2 *C* for 0.234 μm diameter spheres $[(2\pi/k_i)=386\ \mathrm{nm}]$. *B*, Intensity distribution observed for $(\theta, \varphi=0)$ for one of the three single b.c.c. crystals that can nucleate from the structure of Fig. 3*A*. This scattered light is thermal diffuse. The Kossell lines (indicated by arrows) are modifications of the thermal diffuse intensity along pairs of parabolas symmetrically arranged as mirror reflections about the origin, each pair arising from a reciprocal lattice vector and its negative $[(2\pi/k_i)=386\ \mathrm{nm}]$. *C*, Crystal of Fig. 3*B* rotated to $(\theta=-8.1°, \varphi=-11.5°)$ to yield the 011, 211 and 200 Bragg reflections. The b.c.c. 011 spacing is the same as the two-dimensional h.c.p. 10 spacing $[(2\pi/k_i)=344\ \mathrm{nm}]$. *D*, Kossel lines obtained by illumination of a single b.c.c. colloidal crystal orientated as in *B* with a diffuse point source made by focusing the incident laser beam onto a thin Teflon sheet as it enters the cell $(d=0.234\ \mu\mathrm{m}, 2\pi/k_i=386\ \mathrm{nm})$.

all angles to the crystal so the affected rays lie on a cone coaxial with each reciprocal lattice vector (normal to the crystal planes) and at an angle complementary to the Bragg angle[9]. The Kossel lines occur at the parabolic and hyperbolic intersections of these cones with the viewing screen. They appear in X-ray scattering studies of good single crystals and are a sensitive although qualitative indicator of crystal perfection. Motion-induced distortion of a b.c.c. single crystal which has no apparent effect on the Bragg or thermal diffuse scattering can completely eliminate the Kossel lines, which will gradually reappear over several days if the sample is left untouched. The Kossel lines can be viewed alone by illuminating the crystal with diffuse light from a point source, obtained by placing a thin Teflon scatterer in the focused incident laser beam where it enters the cell. The result is shown in Fig. 3*D*.

The b.c.c. crystalline structure bears common features with the randomly stacked two-dimensional h.c.p. from which it nucleates, as indicated in Fig. 4*D*. Both structures are composed of a stack of layers which are parallel to the bounding plates. In the first structure these layers are two-dimensional h.c.ps. In the b.c.c. structure they are distorted two-dimensional h.c.ps, having been stretched in only one dimension, that which becomes the b.c.c. 100 axis (Fig. 4*C*). There seems to be little or no distortion along the other direction (b.c.c. 110 spacing = two-dimensional h.c.p. 10 spacing). The appearance of the b.c.c. is thus accompanied by the disappearance of rows of particles in the two-dimensional h.c.p. layers, perhaps by dislocation motion. If we assume that the overall particle number density remains constant during the transition to b.c.c., the decrease in the number of particles per unit plane area must be accompanied by an increase in the number of planes between the cell walls. For zero density change the two-dimensional h.c.p. layer spacing, c^*, would have to be $(3^{1/2}/2)a$ for a c^*/a^* ratio of 1.83. This somewhat large value may be a result of the shearing which tends to force the spheres into planes normal to the flow gradient. Once the flow is stopped the spheres become too densely packed into layers which are too far apart, and move to form a more energetically favourable structure.

In the conditions of our experiments the crystals were only a few degrees kelvin below their melting temperature, as large room temperature variations would cause partial melting. Recently it has been shown on the basis of an extended Landau theory that, near a weakly first order melting, crystals of spherical particles should exhibit a b.c.c. structure[10]. Our observation of a transition from a metastable two-dimensional h.c.p. layer array structure to a b.c.c. structure provides additional evidence to support this argument.

We thank W. J. O'Sullivan and R. Mockler for their interest in this work, which was supported in part by US Department of Energy contract DE-A502-76ER 02203.

A new phase in solid state arsenic

A. N. Rodionov, R. I. Kalendarev, G. V. Tchikvaidze & J. A. Eiduss

Peter Stuchka Latvian State University, Riga, USSR

It has generally been considered that in the solid state, arsenic exists as four allotropic modifications—yellow (As(I)), amorphous (As(II)), orthorhombic (As(III)), and rhombohedral (As(IV)). Free energy content is lowest for the rhombohedral form. The other forms are metastable, the yellow form being the least stable, existing only at low temperatures and in the dark[1]. It is the yellow form which has been the least studied. Since the effect of temperature, as well as that of irradiation with light or X rays, is to induce amorphisation in yellow arsenic, no X-ray structural data are yet available, and only indirect observations have been available. From these a cubic form has been tentatively assigned to yellow arsenic crystals. Spectroscopic data suggest molecular bonding in the crystal, with the As_4 molecule as the structural unit—a molecule previously observed in the vapour state[2].

There is little information available on the thermodynamic properties of yellow arsenic. This is relevant to attempts to raise the thermal stability margin, thus opening the possibilities of practical application of the material for silverless photography. We have now designed and built a Calvet-type microcalorimeter for studying phase transitions in thin evaporated films. Using this device for differential thermal analysis (DTA) we have obtained DTA curves showing the existence of a previously unknown reversible (endothermic) phase transition within the metastable As(I) yellow form of arsenic which thus contains two states As^1(I) and As^2(I).

The transition curve for As(I) starts at 227 K, reaching a maximum at 230 K. Reversibility was tested by repeated heating–cooling cycles of the calorimeter, the heating being interrupted immediately after termination of endothermic phase transition.

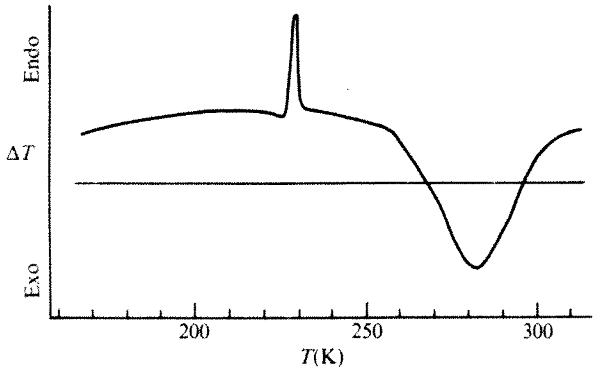

Fig. 1 DTA curve of thin evaporated film of yellow arsenic condensed at 205 K.

Further heating causes the well known exothermic monotropic transition into amorphous arsenic As(II) with liberation of a considerable amount of heat. Both transitions are clearly visible on the thermographic curve shown on Fig. 1.

Direct structural measurements of yellow arsenic have so far proved unsuccessful, however, we can suggest certain estimates based on an analogy with phosphorus, the white form of which can be considered as an analogue of yellow arsenic. White phosphorus is also known to contain two allotropic forms, both based on P_4 molecules as structural units, and differing only by additional rotational degree of freedom. Both forms of yellow arsenic—As^1(I) and As^2(I)—have also been found spectroscopically to contain As_4 molecules which makes the analogy with phosphorus rather feasible.

Stability of the newly discovered yellow phase As^2(I) depends on the thickness of the yellow arsenic layer, the stability increasing with diminution of layer thickness. This may be due to an increase in surface energy with thinning of layer, leading to a rise in amorphisation temperature.

Percolative conduction in microemulsion type systems

B. Lagourette, J. Peyrelasse, C. Boned & M. Clausse*

Université de PAU et des PAYS de l'ADOUR, Institut Universitaire de Recherche Scientifique, Département de Physique, Laboratoire de Thermodynamique, Avenue Philippon, F–64000 PAU France

In the presence of a suitable combination of surfactants (an alkaline metal soap and a medium chain length alcohol, for example), water and oil type organic liquids can form transparent compounds of low viscosity that have been labelled "microemulsions", with little or no mechanical agitation (spontaneous emulsification) (refs 1–3). Depending on the chemical nature of the surface active agents and the relative constituent proportions, water-in-oil (w/o) or oil-in-water (o/w) systems can be obtained. (Because of the similarity between tertiary solutions of inverted micelles and w/o microemulsions, the term 'inverted micellar solutions' has also been suggested[4–7].) Microemulsions have been investigated by many scientists interested in liquid state and surface physicochemistry and by many technologists foreseeing numerous applications in industry[8,9]. It has been suggested[9–13] that conductivity and permittivity studies could provide, along with other techniques, valuable information about the structure and phase behaviour of microemulsions which are considered to consist of dispersions between a few tens and a few hundreds of angströms in diameter globules made up of an inner spherical core surrounded by a concentric shell of mixed surfactant and cosurfactant[1–10]. The experiments reported here show that the conductive behaviour of certain microemulsion systems can be accounted for using the percolation and effective-medium theories[14–16] that have depicted transport properties and continuous metal–non-metal transitions in disordered materials with microscopic inhomogeneities associated with, for example, density, composition[15] or bonding configuration[17] fluctuations. This result, which could help in understanding the structural behaviour of microemulsions, is considered in connection with the postulated existence in liquid systems of equilibrium bicontinuous structures, a state described by Scriven[18] as 'related to ordinary liquids as porous media are to homogeneous solids'.

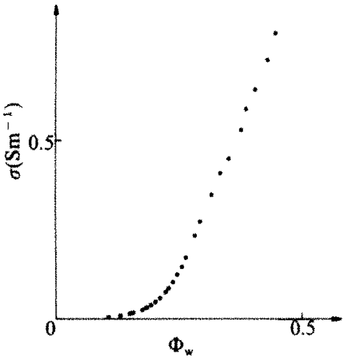

Fig. 1 Variations of σ with Φ_w. The mass fraction of combined surface active agents in the systems was kept at 40%.

Using a Wayne-Kerr B331 autobalance precision bridge, accurate conductivity determinations were obtained at 1.59 kHz and 295 K on w/o type microemulsions involving water and toluene and in which the mass ratio of surfactant (potassium oleate) to cosurfactant (butanol) was kept at 0.5. Unlike previous investigations[9-12,19], measurements were carried out run by run, each run corresponding to a definite class of systems characterised with a fixed value of the mass fraction of combined surface-active agents.

Figure 1 shows the variations of the conductivity σ versus Φ_w, the disperse water volume fraction, recorded on microemulsion systems in which the mass fraction p_s of combined surface-active agents was kept at 40%. Similar plots were obtained on systems characterised by different values of p_s ranging from 30 to 55%. Figure 1 shows that the σ versus Φ_w plot exhibits features characteristic of percolative conduction, the σ experimental values sharply increasing as Φ_w passes a critical value. Kirkpatrick[14] developed, through Monte-Carlo numerical simulations applied to resistor network models, a tractable approach towards percolative conduction phenomena in inhomogeneous media. For conductor–insulator composite materials in which a rigorous percolative conduction is assumed, the effective conductivity σ, zero as long as the conductor volume fraction Φ is smaller than a critical value Φ^P, called the percolation threshold, suddenly takes non-zero values when Φ becomes slightly greater than Φ^P and then increases with Φ. In the vicinity of Φ^P, the dependency of σ on Φ ($\Phi > \Phi^P$) can be demonstrated in the case of three-dimensional systems, by the following scaling law:

$$\sigma(\Phi) \propto (\Phi - \Phi^P)^{8/5} \tag{1}$$

For higher values of Φ, the variations of σ on increasing Φ can be fitted using a relation

$$\sigma(\Phi) \propto (\Phi - \Phi_c) \tag{2}$$

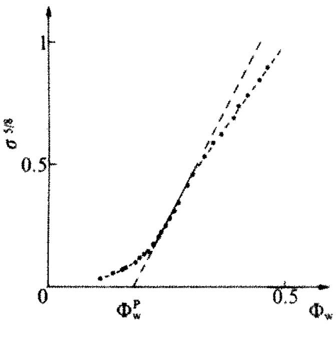

Fig. 2 Determination of Φ^P_w, the water volume fraction corresponding to the percolation threshold, using a scaling law. Specifications as in Fig. 1.

whose range of validity overlaps that of equation (1). It has been shown[14,16] that the B. B. L.[20-22] effective medium formula

$$\frac{\sigma - \sigma_2}{3\sigma} = \frac{\sigma_1 - \sigma_2}{\sigma_1 + 2\sigma}\Phi \tag{3}$$

an expression of the conductivity σ of a binary composite as a function of the conductivities σ_1 and σ_2 of the two of its constituents (Φ being the volume fraction of constituent 1) yields for vanishing values of σ_2 (for conductor–insulator mixtures) an equation of type (2)

$$\sigma/\sigma_1 = \tfrac{3}{2}(\Phi - \tfrac{1}{3}) \tag{4}$$

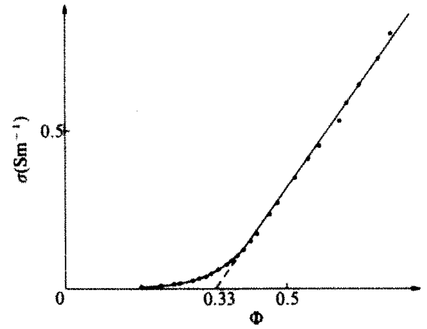

Fig. 3 Variations of σ *with* Φ, the volume fraction of disperse phase (water cores plus shells of combined surface active agents). Specifications as in Fig. 1.

in which Φ_c appears to be 1/3. As mentioned by Kirkpatrick[14], different theoretical values have been suggested for percolation thresholds in three-dimensional systems depending on their geometry. The value $\Phi^P = 0.29$ is of particular relevance to microemulsion studies as it was derived from numerical estimations on a continuum percolation model in which the allowed volumes surrounding percolation sites are assumed to be identical spheres that can overlap and have centres distributed at random. This model is consistent with that inferred from other investigations into microemulsion structure and internal interactions[1-10,19,23]. In the present study, the percolation threshold was determined in terms of water volume fraction by plotting, in accordance with equation (1), $\sigma^{5/8}$ versus Φ_w. Figure 2 shows that the middle part of the plot can be fitted by part of a straight line whose intersection with the Φ_w axis provides Φ^P_w, the critical water volume fraction whose mean value was found to equal 0.176 ± 0.005. Comparing this experimental determination with the theoretical threshold value of 0.29 mentioned above yields the ratio of the disperse globule external radius, a, to the water core radius, a_c, namely $(a/a_c) = 1.18 \pm 0.01$. This value is in excellent agreement with that reported by Lagües *et al.*[19] who found, through neutron scattering measurements, $a/a_c = 1.17$ in the case of water-in-cyclohexane microemulsions using SDS and 1-pentanol as the surface-active agents. Lagües *et al.* suggested for their systems a water critical volume fraction of 0.078. Assuming that the value of the ratio (Φ/Φ_w) as determined from that of (a/a_c) remains unchanged at higher water contents, it was possible to plot the conductivity data versus Φ, the volume fraction of the disperse phase (water cores plus combined surfactant shells), to check whether the microemulsion conductive behaviour beyond the percolation threshold could be fitted by equation (4). Figure 3 shows that, for values of $\Phi > 0.4$, the σ versus Φ diagram is part of a straight line whose intersection with the Φ axis gives $\Phi_c = 0.330 \pm 0.005$, which accords with the value of 1/3 predicted by equation (4). A similar agreement was observed for the other values of p_s. Moreover, whatever the value of p_s, the values $\sigma(1)$ obtained by extrapolating the σ versus Φ plots at $\Phi = 1$ allow values of the slope factor S to be computed which are in excellent agreement with the theoretical value of 3/2 in equation (4); for instance, the value 1.31 S m⁻¹

deduced from Fig. 3 yields $S = 1.51 \pm 0.01$. This general result proves that $\sigma(1)$ can be considered as representative of the conductivity σ_1 of the conducting constituent in the systems, before their inversion into o/w type ones. Note that from Figs 2 and 3, below Φ^P, the conductivity is not strictly equal to zero as it should be were a rigorous percolative conduction exhibited by the microemulsions studied. The non-zero residual conductivity below the percolation threshold could be accounted for on the basis of electrophoretic movements of the disperse globules, as suggested by Peyrelasse *et al.*[24].

These results show that the percolation and effective-medium theories, that are usually applied to semiconductor–metal transitions observed in inhomogeneous systems and to transport properties in amorphous solids, can be extended to the case of microemulsion electrical behaviour. General descriptions of the topological aspects of percolation phenomena in inhomogeneous media have been given by Kirkpatrick[14] and Webman *et al.*[16]. In a conductor–insulator composite, the conducting constituent is divided into isolated clusters as long as its volume fraction Φ remains $<\Phi^P$, bulk conduction phenomena being so inhibited. When Φ reaches and slightly exceeds Φ^P, a certain number of clusters interconnect with each other leading to the formation of a large cluster acting as a conducting path stretched throughout the sample that therefore acquires a non-zero conductivity. When Φ is $>\Phi^P$, the large cluster extends rapidly, by absorbing small isolated clusters which then become less and less, and the sample conductivity increases proportionally to Φ. This scheme may be tentatively applied to the case of microemulsion electrical conductivity, on the basis of the present experimental results. The increase in microemulsion conductivity observed when the water content is raised above the percolation threshold may result from a progressive aqueous droplet interlinking and clustering process. The fact that microemulsion conductive behaviour at higher water contents can be described by the effective-medium theory equation (4), in which the values of Φ are related to those of Φ_w with the constant ratio 1.18 as determined at the percolation threshold, suggests that the clustering process does not affect the membrane-to-water phase volume proportion. This result appears to be an extension of that reported by Lagües and coworkers[19,23] as to the constancy of (a/a_c) with Φ_w increasing up to 0.3 in water-in-cyclohexane microemulsions. Note that the present experiments yield an interesting idea as to the conduction mechanism in microemulsions. The fact that, p_s being fixed, σ increases with Φ while σ_1 remains constant proves that the conduction mechanism taking place in percolating microemulsions is essentially interfacial, as also suggested by Lagües *et al.*[19]. In support of this hypothesis, note that σ_1, which was found to increase proportionally to the amount of surfactant, exhibits values that are lower than those of the corresponding KC1 aqueous solutions. For instance, the value of σ_1, as deduced from Fig. 3, is $1.31\ \mathrm{S\ m^{-1}}$ while the aqueous solution with the same molar fraction of solubilised KC1 would display a conductivity of $4\ \mathrm{S\ m^{-1}}$ or so.

The droplet interlinking and clustering process suggested by the percolative behaviour of microemulsion conductivity might be predictive of the phase inversion phenomenon, the w/o to o/w transition taking place through the constitution of intermediary equilibrium states of the bicontinuous type[18], a statistical model of which was set up by Talmon and Prager[25] who treated 'the microemulsion structure as a random geometry of interspersed oil and water domains generated by a Voronoi tesselation', the surface active agents being assumed to be entirely adsorbed at the water/oil interface.

Primate facial allometry and interpretations of australopithecine variation

Robert S. Corruccini

Carolina, Charlotte, North Carolina 28223

Pilbeam and Gould[1] have discussed African Plio-Pleistocene hominid evolution in the context of allometry (size-dependent morphological change). These authors demonstrate that some general aspects of australopithecine morphology (tooth, brain and body size) support the hypothesis that certain early African hominids were merely scaled variations of each other at different sizes. They also speculate that the methods applied to these very broad anatomical categories can be extended to more specific and detailed traits, especially in the face and cranium. Such traits underlie most taxonomic and phylogenetic discussions of the early African Hominidae, so it is useful to follow Pilbeam and Gould's lead, as we do here, and investigate the structural differences in the australopithecine face and cranium in a quantifiable fashion.

We chose 16 standard measurements of the face and its relation to the neurocranium provided by Tobias[2] for the best preserved australopithecine specimens: *Australopithecus boisei*, represented by Olduvai Hominid 5 (OH 5), and *Australopithecus africanus*, represented by Sterkfontein 5 (Sts 5). The measurements have also been taken on other available australopithecine material (SK 48 and especially KNM-ER 406) although these are less complete and not as well described as the two crania that will be the focus of our analysis. The measurements are listed in Table 1.

Earlier allometric studies of primates[3–12] have relied on bivariate comparisons of measurements. As it is difficult to synthesise the resulting patterns when multiple measurement combinations are involved, we use a multivariate method that allows the growth pattern to be represented as a coherent, covarying entity. A principal component model[13] is available for this purpose but is better suited to intraspecific studies than to the interspecific approach which, like Pilbeam and Gould, we shall use. Thus, for the two fossils, a vector of allometric

0028-0836/79/360062—03$01.00

coefficients (k) can be computed that connects the two points in the logarithmic hyperspace defined by the 16 dimensions[14]:

$$k_i = \frac{(\log x_{i1} - \log x_{i2})p^{1/2}}{[\sum_{j=1}^{p} (\log x_{j1} - \log x_{j2})^2]^{1/2}}$$

where p is the number of measurements and x the array of measurements. This two-dimensional solution is automatically of rank one. These coefficients, which describe the relative changes in proportions with increasing size in the two australopithecine morphs, are compared with the characteristic allometry between primate species. A somewhat novel sampling design is used for non-hominid primates. If all primates were to be treated as a single sample, inherent taxonomic differences which happen to coincide with size changes would be mistakenly identified as allometric in nature. For example, prosimians have quite elongated faces and snouts as well as generally small body size when compared with anthropoids, but this difference is not allometric. Therefore, we have constructed a sample of pairs of closely related but size-differentiated primate taxa, just as we are comparing australopithecine species. The statistical properties of pairwise allometric vectors can be compared with australopithecine values.

For each sampled species the modal-sized individual of five randomly selected male and five female specimens (or less depending on availability) was measured. Each complete pair of taxa yields four vectors, compared between the male and female of one to the two typical individuals of the other. The 12 species pairs result in a sample of 33 allometry vectors that in turn was visually selected from 200 specimens. The dimorphic species pairs are: *Indri indri, Avahi laniger*; *Cheirogaleus major, Microcebus murinus*; *Lemur variegatus, Lepilemur mustelinus*; *Galago crassicaudatus, Galago demidovii*; *Perodicticus potto, Loris tardigradus*; *Saguinus midas, Cebuella pygmaea*; *Ateles belzebuth, Saimiri sciureus*; *Nasalis larvatus, Presbytis melalophus*; *Erythrocebus patas, Cercopithecus talapoin*; *Papio cynocephalus, Macaca fascicularis*; *Hylobates syndactylus, Hylobates klossii*; *Pan gorilla, Pan troglodytes*. The sample pairs consists of four species of genera, six genera within subfamilies and two representatives of the large and small endpoints of families. The exact level of taxonomic distinctness between robust and gracile australopiths remains controversial[15–17], but is probably less than some of the intergroup differences in this comparative sample. Nevertheless, the variation that is non-allometric among the species pairs will be random and non-cumulative compared with that resulting from the consistent size discrepancy.

The allometries are shown in Table 1. Among primates in general, facial breadths are negatively allometric to superior facial length (that is large primates have disproportionately long faces); alveolar height is highly variable; nasal aperture width is positively allometric to its height, but nasal bone width is negative to length; neurocranial measurements are generally negatively allometric to facial measurements, and cranial lengths are positive to the breadths; the foramen magnum area, which is related to brain size[18], has a relatively invariant relationship to other measurements and shows a value near the 0.66 scaling coefficient of brain to body which is characteristic of primates as a whole[12].

Between *A. africanus* (Sts 5) and *A. boisei* (OH 5), shape differences in facial height and the first four parameters of facial breadth co-vary closely with the interspecific primate allometries. This signifies that general primate growth tendencies do satisfactorily explain shape differences within the coronal plane of the face of australopithecines. The relatively narrow nose of the OH 5 specimen, on the other hand, is contrary to the primate trend, and the coefficient for nasal width falls outside the 99% confidence limits for the primate sample. The inferior tapering of the OH 5 nasal bones (characteristic also of other *boisei* and *robustus* specimens) is a unique phenomenon which is in no way accounted for by allometry. The only living primate in which a similar condition exists is the Asian colobine, *Rhinopithecus*. The longer nasal bones of OH 5, however, are again as would be expected from the primate comparative sample. The australopithecine bimastoid (inferior) cranial breadth grows disproportionately relative to other cranial length and breadth measurements but still falls within two standard deviations of the primate mean. The two cranial breadths do not differ nearly as much between australopithecine and primate values as do the three lengths. The small allometry coefficient for horizontal projective length relates to the vertical face and lack of prognathism in OH 5, whereas larger primates are generally more prognathic. This measurement and the related superior length are significantly different in the two lists of coefficients. The average coefficient for facial measurements divided by the average of neurocranial dimensions is 1.75 between OH 5 and Sts 5, indicating the strong rate of allometric increase of face to calvaria. This figure is also positively allometric among primates at 1.26, but the latter value is significantly lower. The smaller foramen magnum of the *A. boisei* specimen also departs sharply from the expected primate value, although cranial capacity itself seems to scale according to the primate norm in all the australopithecines[1].

Table 1 Allometry coefficients comparing facial measurements of two species of *Australopithecus* with the means and s.d. values of primate interspecific allometry coefficients based on the same measurements

Measurement (endpoints)	OH 5-Sts 5	Primates Means	Primates (s.d.)
Inner biorbital breadth (fmo–fmo)	0.64	0.63	(0.19)
Bizygomatic breadth (zy–zy)	0.84	0.80	(0.15)
Maxillary breadth (zm–zm)	0.90	0.89	(0.20)
Anterior interorbital breadth (mf–mf)	1.08	1.07	(0.64)
Superior facial height (n–pr)	1.19	1.10	(0.26)
Cranial length (g–op)	0.49	0.72	(0.17)
Horizontal projective length (pr–i)	0.37	0.87	(0.14)
Superior facial length (ba–pr)	0.35	0.98	(0.14)
Bimastoid breadth (ms–ms)	0.80	0.61	(0.16)
Maximum biparietal breadth	0.39	0.53	(0.16)
Alveolar height (ns–pr)	0.80	0.39	(1.04)
Maximum nasal width	0.28	1.03	(0.20)
Nasal aperture height (ns–rh)	1.03	0.86	(0.33)
Nasal bone inferior breadth	−2.79	0.77	(0.27)
Nasal bone length (n–rh)	1.15	1.28	(0.56)
Foramen magnum (area$^{1/2}$)	−0.18	0.65	(0.11)

fmo, frontomalare orbitale; zy, zygion; zm, zygomaxillare; mf, maxillofrontale; n, nasion; pr, prosthion; g, glabella; op, opisthocranion; i, inion; ba, basion; ms, mastoidale; ns, nasospinale; rh, rhinion.

Thus, there are considerable parallels between the OH 5/Sts 5 australopithecine shape differences and those generally characterising larger and smaller related primates, especially within the face and between the face and neurocranium. However, as previously noted, there are several departures from the primate vector in nasal aperture shape, the nature of the nasal bones, prognathism and foramen magnum area. When the relatively recently discovered East Rudolf 406 robust cranium is substituted for OH 5 in the calculations, identical results to these are obtained except for the larger foramen magnum of ER 406. Swartkrans 48 also yields highly similar allometry coefficients when compared with Sts 5, with the possible exception of aveolar height.

The more general measurements therefore support the hypothesis of Pilbeam and Gould[1] of australopithecine variation, whereas the more specific do not. With regard to the face and cranium, OH 5, KNM-ER 406 and SK 48 in many ways represent scaled-up versions of Sts 5. As the best estimates now indicate that Sts 5 is 0.5–1.0 Myr older than any of these other fossil crania[19–21], our results supplement evidence[22] for evolution of the robust australopithecines in South Africa from antecedent populations resembling *A. africanus* and the subsequent migration of the *A. boisei* stock to East Africa. Further investigation of Johanson and White's recently proposed model[22,23] of early hominid evolution in Africa, using Pilbeam and Gould's allometry hypothesis[1], should include documentation of divergent modes of change between crania of *A. afarensis* with its proposed descendent species *H. habilis* (encephalisation trend) and *A. africanus* (allometric trend).

We thank E. Vrba, C. K. Brain and the staff of the Transvaal Museum, R. E. F. Leakey and the staff of the National Museum of Kenya, and R. Thorington of the Smithsonian Institution for use of the comparative primate material in their charge, and A. Henderson, F. C. Howell, D. C. Johanson, W. Kimbel, Y. Rak and T. D. White for useful criticisms and advice during this study. Project support was provided by the Hrdlicka Scholarship, the Smithsonian Fluid Research Fund and the National Institute of General Medical Sciences.

Protein deprivation causes reversible impairment of mucosal immune response to cholera toxoid/toxin in rat gut

Wayne S. Barry & Nathaniel F. Pierce

Departments of Medicine, Baltimore City Hospitals and Johns Hopkins University School of Medicine, Baltimore, Maryland 21224

Secretory antibodies may be the major defence against mucosal infections, especially those due to viruses and non-invasive pathogens such as *Vibrio cholerae* and toxinogenic *Escherichia coli*. The high incidence of mucosal infections in malnourished protein-deficient children[1] may result from defective antibody production[2], but evidence for this is conflicting[3]. We report here that protein deficiency markedly impairs the mucosal immune response to cholera toxoid/toxin (CT), a protein antigen, in rats and that this impairment is rapidly reversed by refeeding.

Protein deficiency was induced in 7-week-old Wistar–Lewis or Fischer rats weighing 140 g by feeding a low protein (3.2% casein) diet which was otherwise nutritionally complete (LP). The control diet was similar but contained 24% protein (HP). As rats given LP ate more for their weight than those given HP, the diet of LP rats was limiting only for protein. After 6 weeks of HP diet rats weighed 240 g whereas those given LP diets weighed 125 g (serum protein 69% of HP rats). LP rats had lymphoid atrophy but the intestinal mucosa was morphologically normal and they appeared well. Refeeding with HP after 6 weeks of LP diet produced rapid growth; within 2 weeks serum proteins were normal and 50% of the weight deficit was recovered.

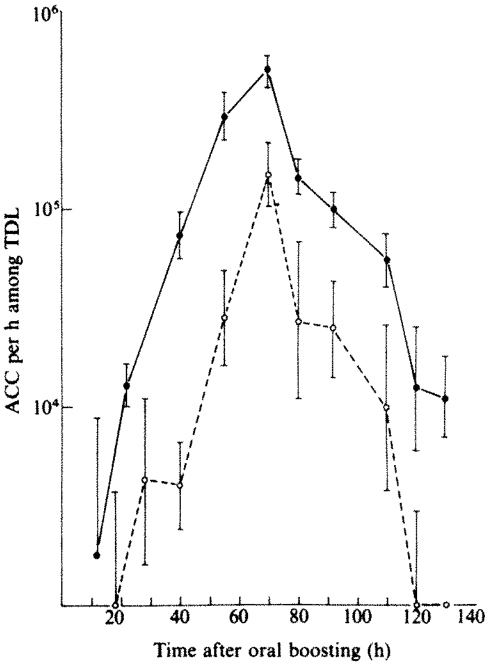

Fig. 1 Antitoxin-containing cells (ACC) among TDL from normal (●) and protein-deficient (○) rats after oral immunisation with CT. Wistar–Lewis rats were begun on test diets at age 7 weeks. For immunisation, CT was given with sodium bicarbonate by intragastric tube to conscious fasting rats. The priming dose was 40 mg crude toxoid (Wellcome) plus 1.5 mg crude toxin (NIH lot 001) given at age 11 weeks. The booster dose was 40 mg crude toxoid given 2 weeks later. These antigens are described elsewhere, as is evidence that this sequence provokes a vigorous mucosal antitoxin response in normal rats[6]. The thoracic duct was cannulated and antitoxin-containing cells among TDL were counted using a fluorescent antibody technique specific for cholera antitoxin[4]. Values are means ± s.e.m. for 3–9 rats given HP or LP diets.

Large thoracic duct lymphocytes (TDL), especially those containing IgA, arise from Peyer's patches and are direct precursors of IgA plasma cells in intestinal lamina propria[4,5]. Table 1 shows the effect of protein deficiency on the number of TDL in unimmunised rats. Diminished numbers of large TDL, including those containing IgA, suggested an impaired mucosal immune response to enteric antigens. This was confirmed in rats immunised orally with CT[6]. HP rats showed numerous antitoxin-containing lymphoblasts among TDL after the second dose of CT; this response was reduced by 73% in rats fed LP 4 weeks before the first dose of CT (Fig. 1). In HP and LP rats more than 96% of antitoxin-containing cells among TDL contained IgA.

Table 1 Thoracic duct lymphocytes (TDL) in unimmunised normal and protein-deficient rats

	Total TDL	Large TDL	TDL containing IgA
HP diet	21	2.1	0.24
	(1.1)	(1.2)	(1.3)
LP diet	9.0	0.61	0.13

Fischer rats were given test diets for 6 weeks starting at age 7 weeks. The thoracic duct was then cannulated for collection of TDL. Total TDL and large TDL were determined with a Coulter counter. The number of IgA-containing TDL was determined by autoradiography with ^{125}I-labelled rabbit F(ab')$_2$ anti-rat IgA[4]. Geometric mean cells $h^{-1} \times 10^{-6}$ ($\overset{\times}{\div}$s.e.m.), $n = 10$; *P* values by Student's *t* test.

0028-0836/79/360064—02$01.00

The antitoxic response in ileal lamina propria was also impaired in LP rats. Feeding LP diet for only 4 weeks (2 weeks before the priming dose of CT) reduced the number of antitoxin-containing cells in ileal mucosa by more than 90%; however, an LP diet begun with priming was without effect (Fig. 2*a*). The mucosal response was also impaired by about 75% when LP rats were primed parenterally (Fig. 3), indicating that impairment was not due to poor absorption of the priming dose of oral CT. Likewise, the impaired response was unlikely to be due to poor absorption of the booster dose as it was at least 20 times the amount needed to produce a maximum response in previously primed normal rats (N.F.P., unpublished observations).

The possibility that refeeding with HP would correct the impaired mucosal immune response was also studied. Despite having had 6 weeks of LP diet, rats refed 2 weeks before starting enteric immunisation showed normal mucosal antitoxin responses; even when refeeding was begun with enteric priming, substantial recovery of responsiveness occurred (Fig. 2*b*).

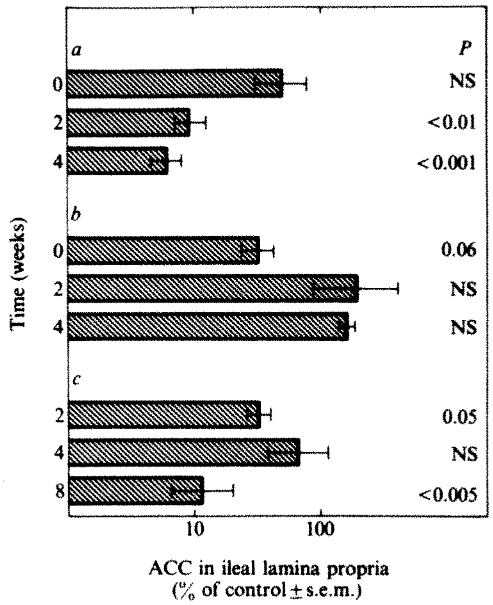

Fig. 2 Antitoxin-containing cells (ACC) in ileal lamina propria of protein-deprived and refed rats. Wistar–Lewis rats were started on LP diets at age 7 weeks. The oral priming and boosting doses of CT are described in Fig. 1 legend. *a*, Time indicates period of LP diet before priming and the LP diet was continued until rats were killed; oral boosting was 2 weeks after priming. *b*, Time indicates period of refeeding before priming. The LP diet was given for 6 weeks, after which HP diet was given. The time of oral priming after refeeding is indicated; oral boosting was 2 weeks after priming. *c*, Time indicates period of LP diet before priming. Oral priming occurred at the indicated interval after starting the LP diet; the diet was continued for 2 weeks after priming; refeeding with HP was then begun and oral boosting was 2 weeks later (4 weeks after oral priming). Scoring of ileal ACC was always 5 days after boosting. Controls were identically immunised and concurrently studied rats given HP diet only. Control responses averaged about 9,000 ACC mm^{-3}. Each group contained 7–17 rats; *P* values were by the *t* test comparing LP rats with concurrently studied controls.

The selective effect of the LP diet on the primary component of the mucosal IgA response was studied by refeeding after enteric priming. Feeding LP for 4 or 6 weeks (2 or 4 weeks before priming), but refeeding with HP 2 weeks before boosting gave a near-normal mucosal antitoxin response; however, extension of the period of LP diet to 8 weeks before priming produced substantial impairment despite refeeding before boosting (Fig. 2*c*).

Thus the ability to mount a specific mucosal IgA response was impaired and corrected by relatively brief periods of protein restriction and refeeding, respectively. The mechanism by which protein deficiency impaired the IgA antitoxin response is unknown and is probably complex. Fewer antitoxin-containing cells among TDL in LP rats indicates that protein deficiency impaired the generation of specific IgA immunoblasts in Peyer's patches[5]; this effect was not specific for antitoxin as non-immune rats had fewer IgA-containing TDL. The greater impairment of the antitoxin response in ileal mucosa (Fig. 2*a*) than among TDL (Fig. 1) suggests that antigen-driven division of immunoblasts in the ileal mucosa[5] was also impaired. Protein deficiency appeared to impair both primary and secondary components of the mucosal immune response; there was direct evidence for an effect on priming (Fig. 2*c*); an effect on boosting is inferred from the shorter period of LP diet required to impair responses in rats not refed before boosting (Fig. 2*a*). The rapid recovery of responsiveness with refeeding parallels the previously described rapid regeneration of atrophic lymphoid tissue when protein-deficient mice are refed[7].

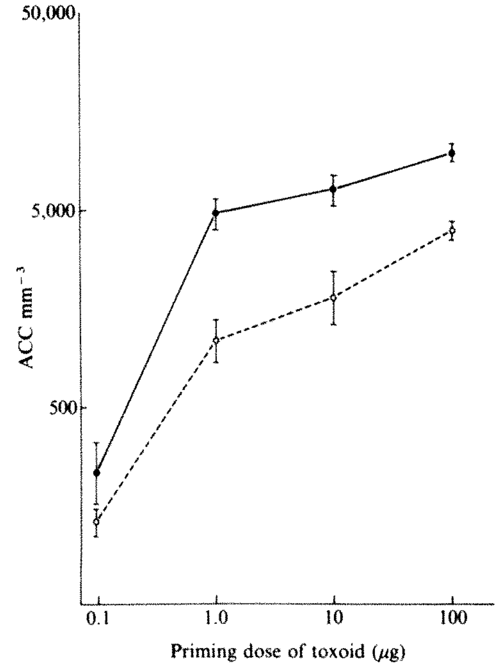

Fig. 3 Effect of protein deficiency on the enteric antitoxin response of rats primed intraperitoneally (i.p.) with purified toxoid. Seven-week-old Wistar–Lewis rats were fed HP (●) or LP (○) diets. Primary immunisation was with purified toxoid (Wellcome) given i.p. (0.1 ml toxoid plus 0.1 ml Freund's complete adjuvant) at age 11 weeks. Intragastric boosting with 40 mg crude toxoid was 2 weeks later. ACC in ileal lamina propria were scored 5 days after boosting; results are geometric mean ± s.e.m., *n* = 5–8 for each value.

We thank Dr Alan F. Williams for anti-rat IgA.

Extra-pituitary inhibition of testicular function by luteinising hormone releasing hormone

A. J. W. Hsueh & G. F. Erickson

Department of Reproductive Medicine, University of California, San Diego, La Jolla, California 92093

Luteinising hormone releasing hormone (LHRH), produced by the hypothalamus, stimulates gonadotropin production by the pituitary[1–3]. Paradoxically, chronic treatment with large doses of LHRH or its agonists causes a decline in testicular steroidogenesis and testicular LH/human chorionic gonadotropin (hCG) receptors; they also cause a decrease in the weight of testes, seminal vesicles and ventral prostate[4–7]. There are three possible mechanisms for the inhibitory action of LHRH and its agonists. At the pituitary level, prolonged action of LHRH or its agonists may make the pituitary refractory to further stimulation by LHRH, with a decrease in serum gonadotropins and subsequent atrophy of the male reproductive organs[8,9]. It is also possible that pharmacological doses of LHRH stimulate the release of a large amount of LH, which in turn 'desensitises' the testis to further LH[10–14]. We have tested a third possibility, namely that LHRH and its agonists act directly on the testis. We report here that LHRH and LHRH agonists cause a decrease in testicular LH/hCG receptors and inhibit testicular steroidogenesis in hypophysectomised male rats, indicating a direct effect on the Leydig cells. This is consistent with our demonstration that LHRH and its agonists act independently of the pituitary to inhibit ovarian steroidogenesis in cultured rat granulosa cells and in hypophysectomised female rats *in vivo*[15].

Immature hypophysectomised male rats were injected daily for 5 d with ovine follicle stimulating hormone (FSH) and/or LHRH analogues or the appropriate vehicle. After hypophysectomy, FSH reduces the general testicular regression and enhances the LH/hCG stimulation of testosterone production[16–19]. Following hormone treatment, animals were killed and testes were removed, decapsulated, weighed and their LH/hCG receptor content and steroidogenic potential determined.

LHRH analogues decreased the testicular weight in both FSH-treated and untreated hypophysectomised rats (Fig. 1*a*). The testes of FSH-treated animals weighed significantly more than the testes of untreated hypophysectomised rats: 139.0 ± 5.1 mg compared with 72.6 ± 1.5 mg (mean ± s.e.m.). Daily injections of [D-Leu^6($N^\alpha Me$)Leu^7]LHRH (analogue I, 200 μg per d) or des-Gly^{10}-[D-Leu^6($N^\alpha Me$)Leu^7,Pro^9-NHEt]LHRH (analogue II, 50 μg per d) decreased the testis weight of FSH-treated animals by 12 and 21%, respectively ($P<0.01$). In untreated hypophysectomised rats, analogue II caused a 20% decrease in testis weight (72.6 ± 1.5 mg to 57.4 ± 2.5 mg; $P<0.01$).

Treatment with LHRH analogues reduced the binding of ^{125}I-hCG to Leydig cells in both FSH-treated and untreated hypophysectomised rats (Fig. 1*b*); binding capacity was 2.1 times greater in the former than the latter. In untreated hypophysectomised rats, analogue II caused a significant decrease in hCG binding ($P<0.01$). Likewise, LHRH analogues I or II given together with FSH significantly decreased FSH-enhanced hCG binding in testicular Leydig cells by 66% and 84%, respectively. Indeed, the effect of analogue II was so great that the testicular LH/hCG receptor content in animals treated with analogue II plus FSH was less than that in animals not treated with FSH ($P<0.01$). Furthermore, LHRH at 50 μg per d also inhibited FSH-enhanced hCG binding by 40%, from 4.21 ± 0.45 ng per testis to 2.51 ± 0.05 ng per testis. The inhibitory effect of LHRH and its analogues was also apparent when hCG binding was expressed as pg hCG bound per mg testis: control, 27.5 ± 1.4; analogue II, 9.6 ± 0.6; FSH-treated, 30.3 ± 3.2; FSH + analogue I, 11.7 ± 1.5; FSH + analogue II, 6.3 ± 0.6; FSH + LHRH, 16.5 ± 0.3.

LHRH analogues also inhibited stimulation of testicular steroidogenesis by hCG. Decapsulated testes were incubated for 3 h at 34 °C in polyethylene vials, half of which contained a saturating concentration of hCG (500 ng ml^{-1}). The androgen concentration in the medium was then determined by testosterone radioimmunoassay[21]. The basal steroidogenic response was low in the control group, and was increased by FSH treatment for 5 d (Fig. 2). In contrast, concomitant administration of analogues I or II together with FSH significantly decreased basal steroidogenesis ($P<0.01$). In the presence of a saturating concentration of hCG, testicular steroidogenesis was stimulated in all groups (Fig. 2, cross-hatched bars). Pretreatment with FSH considerably enhanced the steroidogenic responsiveness of

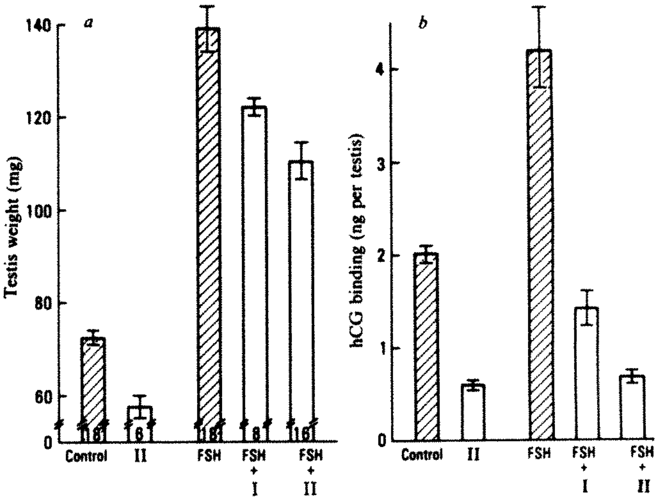

Fig. 1 Effect of treatment with FSH and/or LHRH analogue on testicular weight and ^{125}I-hCG binding capacity of immature (21–23-d-old) hypophysectomised male rats (Hormone Assay Labs). The completeness of hypophysectomy was determined by two parameters. First, 9 d after hypophysectomy of 21-d-old male rats, considerable testicular involution was observed with reduction of testis weight from 169 ± 13 mg to 72.6 ± 1.5 mg. Intact 30-d-old rats have a mean testis weight of 469.4 ± 12 mg. Second, serum LH was measured in hypophysectomised male rats treated with 200 μg LHRH analogue I ([D-Leu^6($N^\alpha Me$)Leu^7]LHRH) or 50 μg analogue II (des-Gly^{10}-[D-Leu^6($N^\alpha Me$)Leu^7,Pro^9-NHEt]LHRH) for 0, 1, 3 and 6 h. In all samples tested, LH in serum was below the limit of detection by LH radioimmunoassay (less than 5 ng NIH-LH-RP-1 per ml). *a*, Beginning 4 days after hypophysectomy, rats received subcutaneous injections daily for 5 d. They received an injection of 50 μg ovine FSH (NIH-FSH-S12) dissolved in 0.1 ml medium 199 with or without an injection of LHRH analogue (200 μg analogue I or 50 μg analogue II) dissolved in 0.1 ml corn oil. Control animals received vehicle alone. Between 20 and 24 h after the last injection, animals were decapitated and their testes were removed, decapsulated and weighed (mean ± s.e.m.). The numbers inside the column indicate the number of testes used. *b*, Decapsulated testes were homogenised in a Kontes ground-glass tissue grinder in ice-cold phosphate buffer (0.01 M, *p*H 7.4) containing 0.15 M NaCl and 0.1% bovine serum albumin (BSA). After centrifugation at 20,000*g* for 15 min, the crude membrane pellet was resuspended to a final concentration of 1 testis per 1.5–3 ml buffer. The concentration of LH/hCG receptors was determined by incubation of serial dilutions of resuspended pellet with a saturating concentration of labelled hCG. Excess unlabelled hCG (100 IU Pregnyl) was added to half of the incubation tubes to obtain nonspecific binding to testis membranes. ^{125}I-hCG (CR-119) was prepared by radioiodination with chloramine T as described previously[20]. The specific activities of the labelled hCG were determined by self-displacement analysis in the radioligand–receptor assay[28] and varied from 20,000 to 80,000 c.p.m. per ng. The fraction of the ^{125}I-hCG able to react specifically with an excess of receptor (that is, the maximum binding activity) was determined for each tracer preparation. This value (45–65%) was used as a correction factor during quantitative analysis of LH/hCG receptor[28]. After incubation of the testicular membrane fraction with ^{125}I-hCG at room temperature (22–24 °C) for 16–18 h, the mixtures were diluted with 3 ml ice-cold buffer and centrifuged at 1,500*g* for 15 min. Pellets were washed once with buffer and then counted in a γ-spectrometer. After correcting for the radioactivity bound to equal aliquots of samples incubated in the presence of an excess of unlabelled hormone, specifically bound radioactive hormone was determined as ng hCG bound per testis. Data represent the mean ± s.e.m. of three experiments.

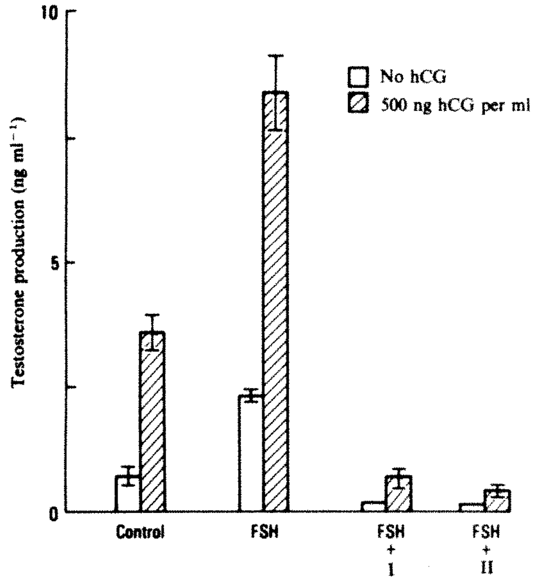

Fig. 2 Effect of treatment with FSH and/or LHRH analogue (I or II) on the steroidogenic capacity of rat testes *in vitro*. Hypophysectomised immature male rats were treated with FSH and/or LHRH analogue as described in Fig. 1. Testes were decapsulated, washed once in ice-cold saline and transferred to polyethylene vials containing 2.0 ml ice-cold medium 199 with 0.1% BSA and 0.1 mM 1-methyl-3-isobutyl xanthine (Aldrich Chemical). Each vial contained one testis, either with or without saturating concentrations of hCG (1,000 ng). All vials were then incubated for 3 h at 34 °C under 95% air, 5% CO_2. Androgen concentration in the incubation medium was measured by specific radioimmunoassay using testosterone antiserum[21]. The antiserum shows no cross-reaction with C_{21} or C_{18} steroids but cross-reacts 100% with dihydrotestosterone, 80% with androstenedione, 30% with 5α-androstanediol and 4% with androsterone. The latter two steroids contribute significantly to total androgen production in immature rats. Three to five samples were used for each point and duplicate determinations were carried out by radioimmunoassay. The results are expressed as mean ± s.e.m.

testes to hCG, whereas a smaller increase was found in untreated hypophysectomised rats. In contrast, concomitant treatment with LHRH analogues I or II markedly depressed the ability of FSH to increase testicular steroidogenic responsiveness to hCG. hCG-induced androgen production in animals treated with FSH plus LHRH analogue is lower than that of control animals receiving no FSH.

These observations indicate that LHRH agonists, in addition to their releasing action at the pituitary gonadotrophs, directly inhibit testicular function. These results may help explain the potent anti-reproductive effect of high doses of LHRH agonists in intact male animals[4-7]. LHRH agonists induce a substantial decrease in LH/hCG receptors as well as decreasing the steroidogenic responsiveness of Leydig cells (Figs 1 and 2). This may, in turn, result in degenerative changes in seminiferous tubules (spermatogenesis), ventral prostate and seminal vesicles[4-7,22]. Although the testis is the most probable site of action of the LHRH agonists, the use of the hypophysectomised male rats in our study does not exclude the possibility that LHRH agonists act on other organs such as the adrenal, resulting in secondary inhibition of the Leydig cells.

The mechanism by which LHRH agonists inhibit Leydig cell function is unknown. Although LHRH binding sites have been identified in the anterior pituitary[23-26], the tissue specificity of the binding has not been demonstrated conclusively. Indeed, Heber *et al.*[27] reported the presence of specific high capacity, low affinity LHRH binding sites in the testis. It is possible that LHRH agonists exert their inhibitory effect through gonadal LHRH receptors. In conclusion, our study provides the first evidence demonstrating an extra-pituitary inhibitory action of LHRH and LHRH agonists on testicular functions in hypophysectomised animals.

We thank Linda Tucker, Li Ng and Cheryl Fabrics for technical assistance, Cheri Anderson for typing, Professor S. S. C. Yen for help, Dr N. Ling for providing LHRH and analogues, Dr G. Abraham for testosterone antiserum, NIAMDD Pituitary Hormone Distribution program for FSH and the Center for Population Research of the NICHHD for hCG. This work was supported by a grant from the NCI (1-RO1-CA 21867) and NIH Research project Grant HD-12303.

Identified neurones isolated from leech CNS make selective connections in culture

Donald F. Ready & John Nicholls

Department of Neurobiology, Stanford University School of Medicine, Stanford, California 94305

Neurones cultured *in vitro* offer distinct advantages for studying how processes grow towards their targets and form synaptic connections. In contrast to the complex events occurring during the development of the nervous system, synapse formation in culture can be analysed in a few neurones at a time and under controlled conditions[1]. We have now dissected out and cultured single identified neurones from the central nervous system (CNS) of the adult leech. Various types of sensory cells, motor cells, and interneurones can be identified in leech ganglia—each with a stereotyped set of properties, including: (1) the electrical characteristics of its membrane, (2) the arborisation of its branches and the morphology of its terminals and (3) the pattern of connections it makes with other identified neurones, skin or muscle[2]. Thus, cultured cells can be compared in detail with their counterparts *in situ*. We have found that isolated cells survive for several weeks, maintain their membrane properties, sprout and form selective connections.

Leech ganglia were dissected under sterile conditions and placed in culture medium consisting of Leibowitz L-15 and 2% fetal calf serum together with glucose 6 mg ml^{-1} and gentamycin 0.1 mg ml^{-1}. The connective tissue capsule was cut (Fig. 1), allowing the neuronal cell bodies to pop out of the large glial cell that normally surrounds them[3]. For identification, the cells

0028-0836/79/360067—03$01.00

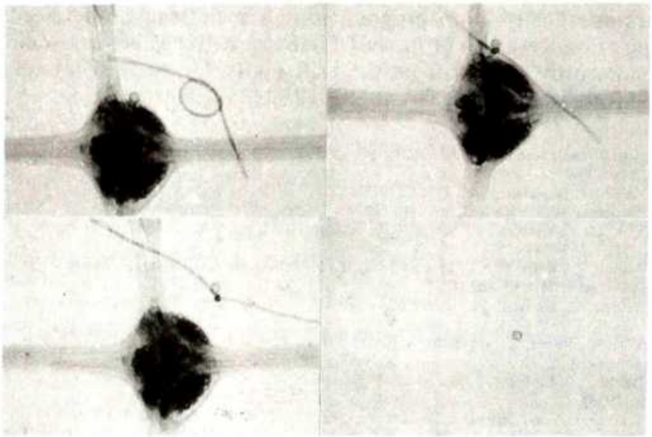

Fig. 1 Steps in the removal of an individual N (nociceptive) cell from a leech ganglion. The diameter of the N cell is about 60 μm.

were impaled with microelectrodes. However, this was not necessary for certain neurones which are unequivocally recognisable by their sizes and positions. Such cells include those used predominantly for the present experiments: the sensory cells that respond to pressure (P cells) and the large Retzius cells that cause mucus secretion. To isolate an identified cell a loop of fine nylon monofilament 13 μm in diameter was tied around its neck, pulled tight and drawn away from the ganglion (Fig. 1*a*). A few minutes later, after the cell had become sealed at the knot, it was freed by gently shaking the thread and transferred to a plastic tissue culture dish, coated with polylysine and collagen and containing approximately 2 ml of culture medium. Dishes were maintained at 20 °C, often without changing medium for 2 weeks.

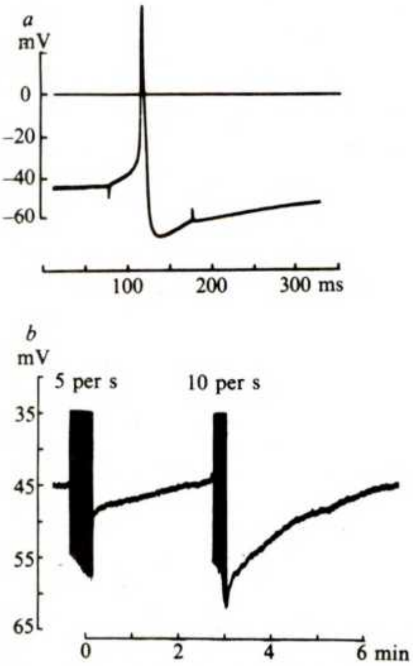

Fig. 2 *a*, Action potential from an N cell isolated for 21 days. The shape and undershoot are identical to those seen in N cells within an intact ganglion. *b*, Afterhyperpolarisation of a P sensory cell isolated for 24 days. Stimuli applied through the microelectrode produced impulses at 5 and 10 per s followed by a prolonged increase in membrane potential. In normal ganglia similar hyperpolarisation is caused by the activity of the Na–K pump and by an increase in K conductance.

For several weeks after removal from the ganglion, individual cells showed normal resting and action potentials. Figure 2*a* shows the action potential of a nociceptive (N) cell which had been kept isolated for 21 days. The shape of its action potential was indistinguishable from that of a normal N cell *in situ* and unlike that of any other type of cell in the ganglion[2]. Similarly, other cells, such as touch cells, pressure cells, and Retzius cells could also be identified unambiguously by electrical criteria and in particular by their characteristic action potentials. These results suggested that the intracellular concentrations of ions and membrane permeabilities were not grossly changed in culture. Further evidence was provided by stimulating cells repetitively. Fig. 2*b* shows the hyperpolarization following trains of impulses in a P sensory cell. The hyperpolarisation was comparable to that observed in normal P cells *in situ*, where it has been shown to arise from a coupled sodium pump and a calcium-dependent increase in potassium conductance[4].

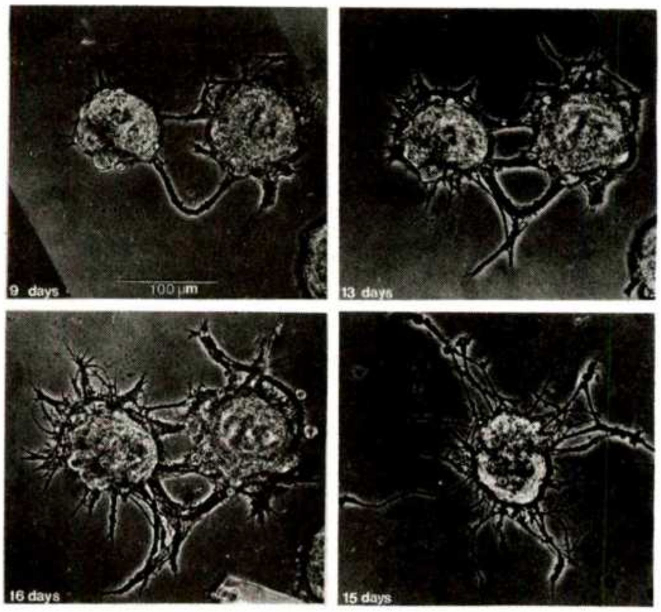

Fig. 3 Development of connections between a pair of Retzius cells over 16 days. Note the preferential distribution of processes running between the two cells and the relative paucity of processes running in other directions. The single neurone (a P cell) cultured on its own, shows more radial distribution of fibres.

After 5 to 7 days in culture, isolated cells began to sprout. Although leech neurones are monopolar *in vivo*, in culture a number of processes extended from the soma (Fig. 3). These processes had typical, filopodia-tipped growth cones, and tended to grow along each other, producing thickened, braided fascicles. Figure 3 shows the growth and development of neurites between two Retzius cells that were placed near one another. In this and other preparations studied over comparable times, bundles of processes were frequently observed passing between the cells, rather than at random. Single cells cultured alone sprouted, but usually without an obvious preferred direction (Fig. 3).

Cultured Retzius cells became electrically coupled and formed chemical synapses. The paired Retzius cells in each ganglion are electrically coupled to each other. When individual Retzius cells were dissected out and placed close to one another as in Fig. 3, or else in contact, they again became electrically coupled: current injected into one cell spread to its neighbour (Fig. 5). As in the animal, current passed equally well in both directions and considerable variation was seen in the degree of coupling, ranging from a minimal spread of current to nearly 1 : 1 coupling.

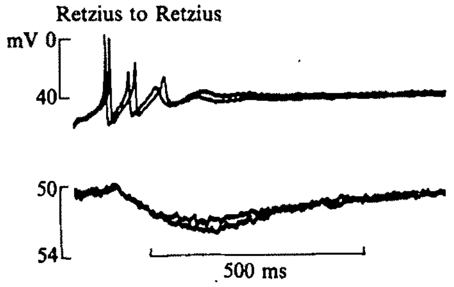

Fig. 4 Chemically mediated inhibitory potentials initiated at 22 days in one Retzius cell (lower trace) by impulses in its neighbour (upper trace). The electrical coupling between these cells was weak (see text). Impulses were initated at the end of hyperpolarising pulse (not shown).

While the development of coupling has not been studied in detail, in most cultures of closely opposed cells coupling first became obvious by about 10 days.

Retzius cells also formed chemical inhibitory synapses upon each other in culture. Figure 4 shows an example from a pair of Retzius cells in which impulses in one cell gave rise to hyperpolarizing potentials in the other with a variable latency. Such potentials were not obvious in cases where the degree of electrical coupling was strong and where the electronically conducted potential tended to obscure events occurring shortly after the spike. For similar reasons it is hard to test for inhibitory connections of this type between Retzius cells within the CNS. Towards the head of the leech, however, ganglia are occasionally found in which the Retzius cells are coupled only weakly and there it may be possible to demonstrate inhibitory connections if they are normally present.

A long-term goal of these experiments is to examine the specificity of connections formed between identified neurones in culture. So far we have obtained one clear example of preferential connections. Retzius cells were paired either with another Retzius cell or with a different neurone, the sensory P cell. In the ganglion the P cells are not electrically coupled to Retzius cells[6]. In five dishes kept from 12 to 24 days, 17 out of 24 pairs of Retzius cells became coupled. In contrast, none out of 22 Retzius–P pairs and none out of 8 P–P pairs became coupled (Fig. 5). In the leech, regenerating neurones reform their connections with a high degree of precision[5]. However, novel connections are occasionally found after lesions have been made to the CNS[7], and when ganglia are isolated in culture[5]. A similar relaxation of specificity may occur when individual cells are isolated and it would not be surprising if novel connections developed between cultured cells. For example, the inhibitory connections between Retzius cells may fall into this category.

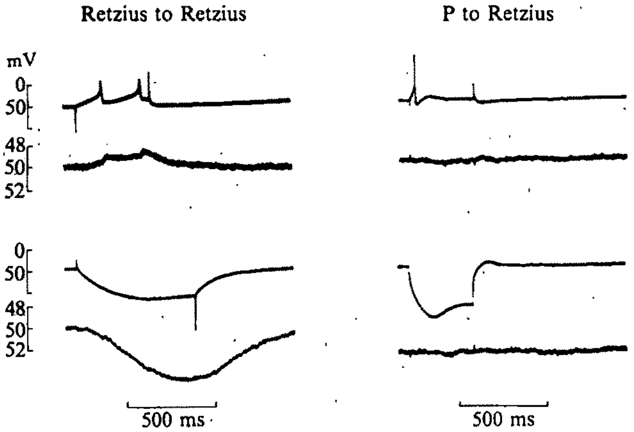

Fig. 5 Specificity of coupling at 24 days between paired Retzius cells (left) and paired Retzius P cells (right). Current spread from Retzius cell to Retzius cell but not from P cell to Retzius cell or vice versa. In this experiment the pairs of cells were in close apposition to one another in the same dish.

We conclude that adult leech neurones can survive well in culture without the large glial cells that normally surround them and can form certain specific electrical connections. The selectivity of connections formed under these conditions presumably depends on inherent properties of the cells rather than on factors such as timing, competition or the availability of sites for synapse formation on the target cell. Given the wide variety of identified cells available in the leech ganglion such experiments could provide a basis for examining in greater detail the preferences that a cell exhibits in relation to a number of different potential target cells.

We thank Drs P. Fuchs, G. Landreth, S. Blackshaw and P. Letourneau for many suggestions and helpful discussion. This work was supported by PHS grant NS11544.

A physiological correlate of disuse-induced sprouting at the neuromuscular junction

W. D. Snider & G. L. Harris

Department of Physiology, School of Medicine, University of North Carolina, Chapel Hill, North Carolina 27514

Recent investigations have established that many of the normal properties of muscle fibres are maintained, at least in part, by muscle activity[1]. Thus, a fall in resting membrane potential[2,3], an increase in input resistance[4], and spread of acetylcholine receptors to extrajunctional sites[4–6] can all be induced by abolishing muscle activity and prevented by direct stimulation of denervated muscle fibres[7,8]. Muscle activity also exerts a trophic influence on the innervating motoneurones[9,10]; furthermore it may be a factor in the regulation of sprouting[11,12]. Brown and Ironton[11] found fine, "ultra-terminal sprouts" emanating from the endplates of muscles rendered inactive by chronic conduction block of the muscle nerve. Pestronk and Drachman[12] saw increased branching of the motor nerve terminal and a consequent increase in endplate size in similar conditions. If these sprouts at the endplates of inactive muscles were functional, one might expect more transmitter to be released in response to nerve stimulation[13]. We report here that both quantum content and spontaneous miniature endplate potential (m.e.p.p.) frequency are increased at the terminals of inactive (disused) muscles.

To effect disuse we used silicone cuffs impregnated with tetrodotoxin (TTX)[6]. TTX (1 mg) buffered with citric acid–sodium citrate (Sankyo) and 20 mg NaCl were dissolved in water; the solution was lyophilised and then mixed with 1.2 ml Silastic 382 (Dow Corning). Polymerising agent was added and the mixture was put in a glass tube (internal diameter, 4 mm) and hollowed out with a 17 gauge hypodermic needle. Female (except one) Sprague–Dawley rats (150–310 g) were anaesthetised with ether. The right or left sciatic nerve (experiments alternated sides) was exposed in the mid-thigh region, and a

2–4-mm segment of the silicone cylinder was slit longitudinally and placed around the nerve. The efficacy of the block was assessed by checking the toe-spreading reflex which is invariably present when a normal animal is suspended by the tail; its absence is assumed to result from conduction block of the sciatic nerve[6]. The initial cuff abolished toe-spreading for 3–7 days. Rats were checked twice daily and a new cuff was implanted as soon as the reflex recovered. In this manner conduction block was maintained for a period of 8–9 days. Second cuffs were not usually as efficacious as the original, and sometimes as many as three changes were required. In some animals control cuffs, prepared as described above (including NaCl and citrate buffer) but without TTX, were implanted around the right or left sciatic nerve and left in place for 8–9 days. The toe-spreading reflex was not affected by the control cuff.

If conduction were blocked for 8–9 days, the animal was anaesthetised with Nembutal, and the soleus muscle, together with a length of muscle nerve, was excised from each leg. The muscles were pinned side by side in a lucite chamber superfused at room temperature by a solution of (mM): NaCl 136.8; KCl 5.0; $CaCl_2$ 1.0; $MgCl_2$ 8.0; NaH_2PO_4 1.0; $NaHCO_3$ 15.0, through which 95% O_2 plus 5% CO_2 was continuously bubbled. Neostigmine methylsulphate (10^{-6} M) was included in the solution to enhance the m.e.p.ps. Muscle fibres were impaled with conventional microelectrodes filled with 2.6 M KCl. Those fibres with a resting membrane potential of greater than 55 mV in which m.e.p.ps could be distinguished clearly were selected for determination of quantum content. On stimulating the muscle nerve at a frequency of 0.5 s^{-1}, ~200 endplate potentials (e.p.ps), then approximately 50 s of spontaneous m.e.p.ps were recorded. Recordings were taken alternately from disused and control muscles. Quantum content (m) was estimated by the method of failures[14] except for a few endplates where no failures occurred and m was calculated from the coefficient of variation of the e.p.p. amplitude distribution[14]. When both methods were applied for purposes of comparison (12 endplates), the m values agreed to within 15% of the average.

Table 1 Quantum contents at disused and control endplates

Expt	M_{TTX}	M_{con}	Ratio (M_{TTX}/M_{con})
1	2.3	1.8	1.3
2	2.9	1.8	1.6
3	3.3	1.8	1.8
4	3.4	3.5	1.0
5	4.9	4.2	1.2
6	3.2	2.4	1.3
7	2.2	1.4	1.6

M_{TTX} is the mean m of soleus endplates on the side where conduction of the sciatic nerve was chronically (8–9 days) blocked with TTX cuffs. M_{con} is the mean m of control endplates on the contralateral side. At least five fibres were sampled on each side.

Table 1 shows results obtained from seven animals. M_{TTX} represents the mean of m values determined at 5–7 soleus endplates on the disused side. M_{con} is the similarly determined mean from the contralateral control soleus of the same animal. The mean m of junctions from disused muscles was greater than that on the control side in six out of seven experiments, the average difference being 40%. These data were analysed with the two-tailed t test for matched pairs. The difference in mean quantum content between the disused and control sides was highly significant ($0.005 < P < 0.01$), and remained significant even when the two highest ratios (M_{TTX}/M_{con}) were excluded (expts 2, 3).

Table 2 presents data from five control animals, M_{cuff} being the mean m value of soleus endplates from the leg in which a control cuff (see above) had been placed. M_{con} is again from the contralateral control soleus. No significant difference in mean quantum content between the two sides was noted ($0.20 < P < 0.30$).

Table 2 Quantum contents from control animals

Expt	M_{cuff}	M_{con}	Ratio (M_{cuff}/M_{con})
1	1.5	1.5	1.0
2	1.7	2.2	0.8
3	1.3	1.3	1.0
4	2.5	2.4	1.0
5	1.3	1.6	0.8

M_{cuff} is the mean m of soleus endplates from the leg in which a control cuff had been placed. M_{con} is the mean m from the contralateral soleus.

At the amphibian neuromuscular junction, quantum content and spontaneous m.e.p.p. frequency (f) are positively correlated with endplate size[13]. If the terminal area is enlarged by sprouting, then one might expect f to increase as well as m. We made determinations of f from at least four disused and four control fibres in each of five experiments. After 8 days of disuse, f at junctions from disused muscles was higher than at contralateral control junctions in all five preparations. The mean values were respectively $1.2 \pm 1.0\ s^{-1}$ and $0.7 \pm 0.4\ s^{-1}$. With the matched pairs t test, f on the disused side was significantly higher ($0.02 < P < 0.05$). Animals prepared with control cuffs showed no significant differences in f between the cuff and contralateral sides. However, as was the case at soleus endplates in the mouse (S. T. Carbonetto and J. N. Weakly, personal communication), f and m were not significantly correlated in our data. One explanation may be that f and m vary less at mammalian than at amphibian endplates. For example, the coefficient of variation of m values from our control rat solei is 0.5, whereas in frog sartorius it is 1.2 (M. Kuno, S. A. Turkanis and J. N. Weakly, personal communication). The variability of f values from the two preparations is also quite different.

One might argue that the presence of the cuff could itself result in degeneration of some motor axons, and that partial denervation rather than disuse might account for these results. However, application of control cuffs did not result in any significant change in quantum content on the cuff side. Moreover, we did not observe fibrillation in any preparation, implying that most or all motor axons remained intact. Disuse itself has been reported to cause fibrillation[3,4], but work in the cat[9,15] agrees with our finding of none. We have no explanation for this discrepancy.

The present results indicate that at the neuromuscular junctions of chronically disused muscles, presynaptic terminals release increased amounts of transmitter in response to nerve stimulation and exhibit increased spontaneous release of acetylcholine quanta. These observations are consistent with the hypothesis that chronic disuse enlarges the functional endplate area, possibly as a result of increased terminal fibre branching and endplate length reported by Pestronk *et al.*[12]. Lømo and Rosenthal[4] have suggested that quantum content may be increased at the junctions of disused soleus muscles (slow twitch) but not those of disused extensor digitorum longus muscles (fast twitch). In the mouse, soleus endplates sprout more vigorously than peroneus tertius (fast twitch) endplates in response to disuse[11]. These findings suggest that fast and slow twitch muscles may differ in their ability to produce the signal for sprouting, or that there may be differences in the ability of their motor terminals to respond.

Disuse may affect transmitter release in other ways; for example, the membrane properties of presynaptic terminals may change, thereby affecting quantum content. While we cannot exclude this possibility, it is not clear how such changes in membrane properties would also increase spontaneous m.e.p.p. frequency. With respect to the signal that may trigger this increase in quantum content, it remains uncertain whether muscle inactivity or the disused terminals themselves are responsible. It is interesting in this regard that Gallego *et al.*[15] have reported an increase in synaptic efficacy at the disused Ia synapses of spinal motoneurones.

We thank Professor Motoy Kuno for his guidance and criticism. GABA may be a neurotransmitter in the vertebrate peripheral nervous system

Kristján R. Jessen, Rhona Mirsky*, Marion E. Dennison & Geoffrey Burnstock

Department of Anatomy and Embryology, University College London, Gower Street, London WC1, UK

γ-Aminobutyric acid (GABA) is an inhibitory neurotransmitter in the peripheral nervous system of certain invertebrates and is thought to be a major transmitter in the vertebrate central nervous system[1–3]. In this report we present evidence that GABA may also be a neurotransmitter in the vertebrate peripheral autonomic nervous system. We have used light and electron microscopic autoradiography to analyse high-affinity uptake of ^{3}H-GABA into the myenteric plexus of the guinea pig taenia coli, both *in situ* and in a tissue culture preparation. In the isolated myenteric plexus, we have measured the specific activity of glutamic acid decarboxylase (GAD; EC 4.1.1.15), the enzyme responsible for conversion of glutamic acid to GABA in GABAergic neurones[4,5], and assessed the ability of this tissue to accumulate ^{3}H-GABA newly synthesised from ^{3}H-glutamic acid. Furthermore, we have measured the levels of endogenous GABA in strips of taenia coli containing the myenteric plexus.

For autoradiography, myenteric plexus from 1–8-day-old guinea pigs grown *in vitro* as described previously[6] was incubated in Krebs solution containing 2×10^{-8} M ^{3}H-GABA (1 μCi ml^{-1}, 66 Ci mmole^{-1}; [2,3-^{3}H]GABA, Radiochemical Centre) and 10^{-3} M β-alanine to block non-neuronal uptake of GABA[7]. After 20 min incubation at 20 °C, the samples were washed with Krebs solution, fixed in 4% glutaraldehyde in Krebs solution, washed with distilled water, air dried, dipped in Ilford L-4 or Kodak NTB2 emulsion and developed with Agfa Rhodinal developer after exposure for 10–14 days. Examination by light microscopy showed that although the density of silver grains was low over the non-neuronal cells and almost totally absent from most of the neurones, some neurones in the cultures were heavily labelled with grains (Figs 1, 2). Labelling was restricted to small ($\sim16\times17$ μm) to medium-sized neurones, the large neurones ($\sim40\times27$ μm) always being unlabelled. The grains seemed evenly distributed over the nucleus, cytoplasm and neuronal processes. The cell bodies were of various shapes and the labelled axons emanating from them could often be traced over long distances in the cultures, in some cases running together with unlabelled axons in thick axon bundles, but in others lying singly within the explants or in the outgrowth zones around them.

The heavy labelling was totally absent if 10^{-3} M *cis*-1,3-aminocyclohexane carboxylic acid (ACHC), an inhibitor of neuronal GABA uptake[8], was included in the incubation medium, thus confirming the morphological identification of the labelled cells as neurones. If the cultures were incubated without β-alanine but in the presence of 10^{-3} M ACHC a few cells within the explant were moderately labelled. This labelling was blocked by 10^{-3} M β-alanine and probably occurred over glial cells. Explant cultures of rat thoracic sympathetic ganglia showed no neuronal autoradiographic labelling in any of the above conditions.

These findings were extended by electron microscopic autoradiography of the myenteric plexus *in situ*. Taenia coli containing the myenteric plexus were dissected from 1-day to 3-month old guinea pigs and incubated with ^{3}H-GABA as

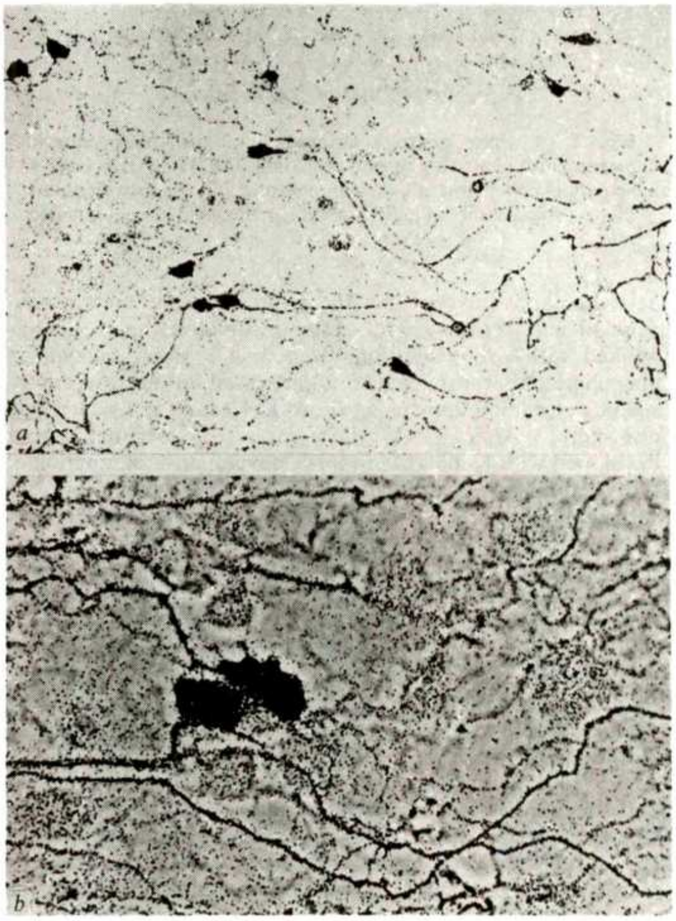

Fig. 1 Autoradiograph of myenteric plexus cultured for 10 d before incubation with ^{3}H-GABA. *a*, Bright field photograph showing the border between the explant (left hand side) and the outgrowth zone (right hand side). Radioactivity is concentrated over 10 neuronal cell bodies, most of which lie within the explant, and processes which are mainly seen in the outgrowth zone. The light background labelling, which is most noticeable within the explant, is over non-neuronal cells (×540). *b*, Phase contrast photograph of two heavily labelled neurones and their processes lying in the outgrowth zone. Note other labelled processes as well as light labelling concentrated over the nuclear areas of non-neuronal cells which form a continuous sheet underlying the neuronal elements of the outgrowth zone. The camera was focused on the autoradiographic grains (×720).

0028-0836/79/360071–04$01.00

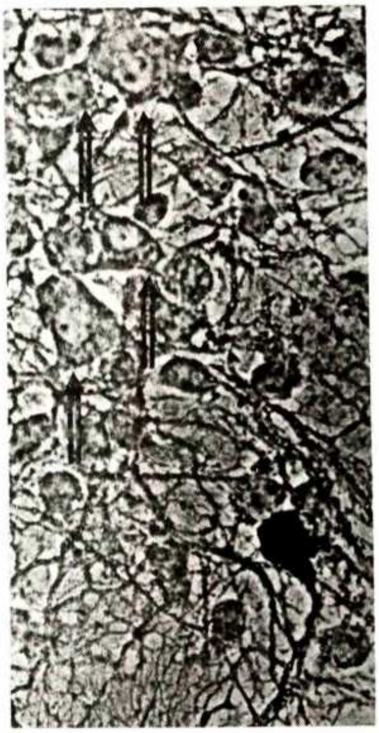

Fig. 2 A phase contrast autoradiograph of the myenteric plexus cultured for 12 d before incubation with ^{3}H-GABA. Radioactivity is concentrated over one neurone and the proximal part of its process; the other neurones in the field are unlabelled (arrows) (×630).

described above except that the incubation solution was oxygenated and kept at 37 °C. After incubation the tissue was washed with Krebs solution, fixed in 4% glutaraldehyde in phosphate buffer, osmicated and processed for electron microscopic autoradiography using Ilford L-4 emulsion as described elsewhere[9]. After 21–28 days exposure, specimens were developed with Kodak Microdol-X developer. Examination of thin sections through individual ganglia of the plexus and the surrounding smooth muscle showed three degrees of labelling (Fig. 3): heavy labelling over approximately 5% of the neurones in the ganglia and over some axons in nerve bundles running through the smooth muscle coat, light labelling over the glial cells of the ganglia and almost total absence of label over the smooth muscle and fibroblasts outside the ganglia and most of the neurones within the ganglia. The labelled neurones were small to medium sized, as far as could be judged by the examination of single thin sections, and were often elongated and found at the surface of the ganglia as illustrated in Fig. 3. The cytoplasm was fairly dark, being packed with free ribosomes and rough endoplasmic reticulum and the mitochondria were small and electron dense. They most closely resembled neuronal type 1 in the ultrastructural classification of myenteric neurones proposed by Cook and G.B.[10], the main discrepancy being the absence of accompanying satellite cells around the labelled neurones. The neuronal labelling, especially inside the ganglia, was greatly reduced if 10^{-3} M ACHC was present in the incubation medium. Thus, there is good agreement between the results obtained from the *in situ* and *in vitro* experiments both with respect to the distribution of label and the effects of uptake inhibitors.

Current evidence indicates that the only vertebrate neurones to possess a high-affinity uptake mechanism for GABA are GABAergic neurones, although it is uncertain whether all GABAergic neurones share this property[11,12]. This has recently received support from studies on ^{3}H-GABA uptake into spinal cord neurones in culture, where it was shown that no identifiable cholinergic neurones showed high-affinity GABA uptake[13]. The results above therefore raised the question as to whether there are GABAergic neurones in the myenteric plexus. If there are, the plexus should contain GAD and be able to accumulate newly synthesised GABA. Furthermore, it should contain endogenous GABA, and pharmacological actions of GABA in the gut ought to be detectable.

We measured the specific activity of GAD by formation of labelled GABA from labelled glutamic acid as described by others[14], in three separate experiments. The plexus from the taenia coli of 1–8-day-old guinea pigs, dissected completely free of smooth muscle as described previously[6], was homogenised in ice-cold distilled water and incubated at 37 °C for 15, 30 and 60 min in a solution containing the following components (final concentrations): potassium phosphate, *p*H 6.5, 0.1 M; dithiothreitol, 0.5 mM; pyridoxal phosphate, 0.5 mM; sodium L-glutamate, 25 mM; L-[*G*-^{3}H]glutamic acid, 500 μCi ml^{-1}, electrophoretically purified (specific activity 31 Ci mmol^{-1}, Radiochemical Centre). The total amount of protein in each experiment was 30–50 μg. This was divided into six samples and the levels of ^{3}H-GABA obtained were 1.5 to 5 times higher than the assay blanks. Significant levels of GAD were detectable, the specific activity being 2.18 ± 1.2 μmol per h per 0.1 g protein.

Neurones can not only synthesise but also accumulate in high concentrations the transmitter they use. We therefore investigated whether accumulation of GABA in intact cells of the myenteric plexus could be detected following incubation of the tissue with radiolabelled glutamic acid[15]. For comparison, we also studied slices of rat cerebellar cortex, which contains GABAergic neurones[4,5], and rat superior cervical ganglion,

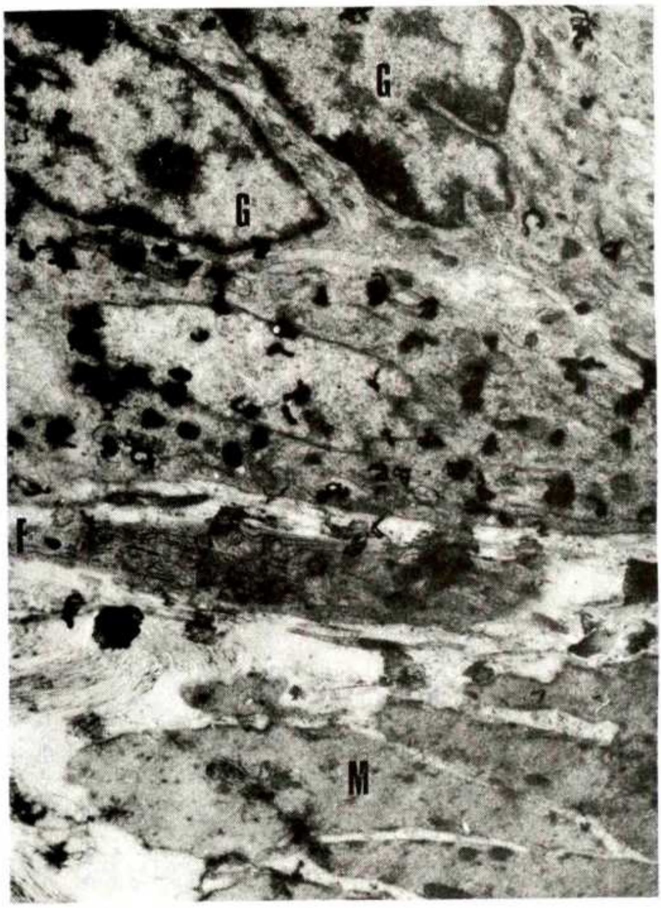

Fig. 3 Electron microscopic autoradiograph of the myenteric plexus incubated *in situ* with ^{3}H-GABA. The micrograph shows the edge of a ganglion with two slightly labelled glial cells (G), identifiable by the morphology of the nucleus[31], a heavily labelled neurone, a fibroblast (F) in the interstitial space between the ganglion and the surrounding muscle, and a part of the muscle layer (M), all of which are virtually unlabelled (×13,000).

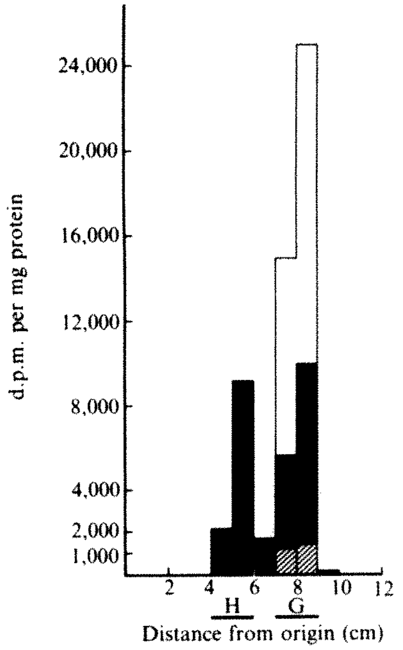

Fig. 4 Paper chromatography of ^{3}H-GABA and ^{3}H-homocarnosine synthesised from ^{3}H-glutamic acid in myenteric plexus (solid columns), cerebellum (open columns) and superior cervical ganglion (cross-hatched columns). The figure shows the distribution of radioactivity expressed as d.p.m. per mg protein based on results from three representative experiments, one for each tissue. The bars mark the position of non-radioactive homocarnosine (H) and GABA (G) on the chromatogram. The tissues were incubated in two changes of Eagle's minimum essential medium containing 6 g l^{-1} glucose and 10% fetal calf serum, for 40 min. The tissues were then placed in the same medium containing 4×10^{-6} M ^{3}H-glutamic acid, 100 μCi $mmol^{-1}$ (23 Ci $mmol^{-1}$; Radiochemical Centre) for 17 h at 37 °C. In one experiment electrophoretically purified ^{3}H-glutamic acid was used. After the incubation the samples were washed in two changes of phosphate-buffered saline, containing 150 mg l^{-1} non-radioactive glutamic acid, for 40 min and homogenised in 20 μl of ice-cold distilled water. A 5-μl sample of homogenate was withdrawn for protein estimation[32] and 20 μl of 0.47 M formic acid, 1.4 M acetic acid containing 1 mg ml^{-1} of glutamic acid, GABA and in some cases homocarnosine was added to the remainder of the sample, which was frozen and thawed three times before being subjected to high-voltage paper electrophoresis[33]. The paper was dried and ascending chromatography in *n*-butanol/acetic acid/water (60:15:25)[17] was carried out at right angles to the direction of electrophoresis. The figure shows the distribution of radioactivity resulting from chromatography of that section of the paper to which non-radioactive GABA ran in the electrophoresis. In other experiments not shown here, *t*-butyl alcohol/methyl ethyl ketone/water/formic acid (8:6:5:1)[21] was used as the solvent system. The amino compounds were visualised with ninhydrin spray, the paper cut into strips 1 cm long and 3.2 cm wide, the radioactivity eluted with 0.1 M HCl, followed by 4.5 ml of Aquasol (NEN) and counted in a scintillation counter.

where there is no evidence of GABAergic neurones[16,17]. Isolated myenteric plexus, 400-μm thick slices of cerebellar cortex and desheathed superior cervical ganglia from 4–6-week-old rats were incubated with ^{3}H-glutamic acid for 17 h at 37 °C. They were then homogenised and analysed for the presence of radioactive products of ^{3}H-glutamic acid by electrophoresis, chromatography in two different systems and subsequent scintillation counting. The results are shown in Fig. 4. The myenteric plexus, cerebellum and superior cervical ganglion all converted ^{3}H-glutamic acid to ^{3}H-GABA. The myenteric plexus contained 20,100±3,000 d.p.m. or 4.0×10^{-13} mol of ^{3}H-GABA per mg protein, the cerebellum contained 41,500±11,000 d.p.m. or 8.0×10^{-13} mol of ^{3}H-GABA per mg protein and the superior cervical ganglion contained 4,800±1,300 d.p.m. or 9.6×10^{-14} mol per mg protein. Each value is an average of four experiments, all using the *n*-butanol/acetic acid/water chromatography system as described in Fig. 4 legend. In medium incubated without tissue no conversion was detectable. Thus, in these incubation conditions both the myenteric plexus and cerebellum contained significantly greater quantities of ^{3}H-GABA than the superior cervical ganglion, where synthesis and accumulation of ^{3}H-GABA apparently takes place in glial cells only[16–19].

In the case of myenteric plexus about 40% of the radioactivity running with non-radioactive GABA in the high-voltage electrophoresis separated from it in subsequent chromatography, forming a second peak of radioactivity. We found that homocarnosine (γ-aminobutyryl-L-histidine), a dipeptide which can be formed from GABA and histidine[20], also ran in the same position as GABA on the high-voltage electrophoresis and separated from it in two separate chromatography systems to run in an identical position to the second radioactive peak. We therefore conclude that this peak, which amounted to 13,400±2,200 d.p.m., is homocarnosine. The absence of ^{3}H-homocarnosine from the rat cerebellar cortex and superior cervical ganglion is not merely due to a species difference in GABA metabolism, as no ^{3}H-homocarnosine was detected in similar experiments with guinea pig superior cervical ganglia and cerebellar cortex, where similar levels of ^{3}H-GABA to those in the rat tissues were accumulated. We know of no other report on the synthesis or occurrence of homocarnosine in tissues other than brain. There it is present in low amounts but with heterogeneous distribution which, contrary to earlier beliefs, does not parallel that of GABA[21]. Homocarnosine is a potent anti-seizure agent[22,23], causes hyper-excitability and shortens barbiturate sleeping time[24] when injected into cerebral ventricles, and has been postulated to be a central neurotransmitter[25]. Considerable evidence has also accumulated that carnosine, a related dipeptide (β-alanyl-L-histidine), may be a neurotransmitter in the olfactory bulb[26].

When measuring endogenous GABA levels, the rapid and significant accumulation of GABA which takes place after the death of the animal, must be taken into account[27]. Thus, GABA levels in the myenteric plexus would probably increase substantially during the time it takes to dissect it from the gut wall. To assess whether the plexus contained GABA we therefore compared GABA levels in strips of taenias containing the plexus to those in muscle (gastrocnemius) which does not contain the plexus, both tissues being removed from living anaesthetised guinea pigs and frozen immediately in liquid N_2. The samples were then extracted twice with 80% ethanol, freeze dried and analysed for the presence of GABA with an automated amino acid analyser with a fluorimeter attached[27]. Three experiments gave a value of 17.5±3.1 nmol GABA per g wet weight of tissue for taenia coli compared with 5.7±0.1 nmol GABA per g wet weight of tissue for muscle. The difference between the two tissues can probably be attributed to the myenteric plexus, in which case, if it were possible to measure endogenous GABA levels in the myenteric plexus alone, the values would be considerably higher than those reported here, as in the taenia the plexus is embedded in a large mass of muscle.

Few studies have been carried out on the action of GABA in the gastrointestinal tract. However, Hobbiger reported that 10^{-5} M GABA blocked the peristaltic reflex of the guinea pig ileum although it did not seem to act directly on smooth muscle. A variety of other effects of GABA on gut preparations have led to the suggestion that it may serve as a neurotransmitter[28–30].

Thus, we have shown that a small population of neurones in the myenteric plexus possesses a high-affinity uptake mechanism for GABA. These neurones are small to medium sized and share several common ultrastructural characteristics. Furthermore, the myenteric plexus contains GAD and endogenous GABA and can synthesise and accumulate ^{3}H-GABA and ^{3}H-homocarnosine from ^{3}H-glutamic acid. The complexities of GABA metabolism and compartmentation are such that these results should be interpreted with caution. However, in conjunction with the pharmacological evidence that GABA affects intestinal peristalsis, the results suggest that it may have a role in neuronal transmission in the gut.

The ACHC was a gift from Dr M. Neal. We thank Dr R. Purves for critical comments on the manuscript and Janet Winter, George Barrett and Stuart Waterman for technical and photographic assistance. Mr A. Hunt of the MRC Developmental Neurobiology Unit performed the amino acid analyses. R.M. is supported by Action Research for the Crippled Child. This work was supported by the MRC.

Expression of a liver-specific function by mouse fibroblast nuclei transplanted into rat hepatoma cytoplasts

Leah Ann Lipsich, Joseph R. Kates & Joseph J. Lucas

Department of Microbiology, Health Sciences Center, State University of New York at Stony Brook, Stony Brook, New York 11794

Data from many somatic cell fusion experiments support the notion that the cytoplasm of eukaryotic cells contains elements which can alter gene expression and replication[1]. More definitive evidence is perhaps lacking because the cell hybrids studied were complex cells comprising mixed genomes, frequently undergoing chromosomal losses and other aberrations, within mixed cytoplasms. Such problems have been alleviated by the development of the techniques of cybridisation, red cell-mediated microinjection and nuclear transplantation[2]. Using this last technique, we showed that up to 40% of a monolayer culture of cytoplasts could be renucleated to form whole viable cells[3,4]. Because of the high efficiency of fusion and the purity of cytoplast and karyoplast cultures used, large quantities of true cytoplasmic–nuclear hybrid cells suitable for immediate morphological and biochemical analysis could be formed. Here we describe the application of the technique to an investigation of the effects of rat liver cytoplasm on gene expression by mouse fibroblast nuclei. We show that the synthesis of mouse tryosine amino transferase (TAT)—a liver-specific enzyme never detected in the fibroblast cell line was induced in hybrids constructed by transplantation of mouse (A9) fibroblast nuclei into rat liver (HTC) cytoplasts. Furthermore, as occurs in the rat cell line, its activity was modulated by addition of the synthetic corticosteroid, dexamethasone. Clearly, this hybrid cell system will be useful in the further characterisation and eventual isolation of the newly identified regulatory substance.

First, hybrid cells were formed and identified using our previously described techniques[3]. Briefly, cytoplasts were prepared from the HTC rat hepatoma cell line, which can be routinely enucleated with a >99% efficiency. Monolayer cultures of cytoplasts were treated with inactivated Sendai virus, after which excess unabsorbed virus was removed and replaced by a suspension of karyoplasts prepared from the A9 mouse fibroblast cell line. After fusion, the dishes were washed vigorously to remove virus and excess unfused karyoplasts. Freshly prepared karyoplasts cannot adhere to a surface; only those fused to the cytoplast monolayer will remain associated with the dish. Approximately 20% of the HTC cytoplasts were routinely renucleated, with the value ranging from 10 to 30% in over 30 separate experiments. In cultures in which karyoplasts were layered over cytoplasts in the absence of virus, fewer than 1% of bodies contained nuclei, these cells being that small fraction of HTC cells not originally encleated during centrifugation in medium containing cytochalasin B (see ref. 3 and below). Figure 1*a* shows an A9 nucleus–HTC cytoplast hybrid cell culture 18 h after fusion. By this time most cytoplasts not receiving nuclei have died and disintegrated. On the second day after fusion, medium containing 8-azaguanine was placed on the cells. The A9 nucleus does not code for the enzyme hypoxathine–guanine phosphoribosyl transferase (HGPRT); thus, hybrids should also be resistant to the toxic analogue. As shown in Fig. 1*b*, the culture continued to grow (in fact, these cells were subcultured several times during the 2 weeks of growth), whereas a culture of whole HTC cells died within this time (Fig. 1*c*). The addition of azaguanine was delayed for 2 days to permit degradation of HGPRT contributed to the hybrids by the HTC cytoplasm[3].

It was established, therefore, that the A9–HTC hybrids were viable and that they retained a genetic marker of the mouse nuclear donor cell. Furthermore, use of azaguanine permitted elimination of the small background of whole HTC cells originally contaminating the cytoplast cultures. As further proof that the cells contained mouse nuclei, karyotyping[5] was carried out. Distinction between the two nuclei is possible as HTC cells contain several matacentric marker chromosomes[6] whereas the mouse cells contain primarily telocentric chromosomes. Metaphase chromosome spreads were prepared from A9, HTC and hybrid cells (grown for 2 weeks) and scored for the presence of metacentric chromosomes. 100% of spreads from HTC cells contained metacentric chromosomes whereas 8% of spreads from A9 cells contained chromosomes that were scored as metacentric. Of all spreads examined from hybrid cells, only 4% contained chromosomes appearing metacentric. Thus, these results suggested that the constructed cells contained mouse, not rat, nuclei. Note also that hybrids could be formed, using similar techniques, by fusion of A9 cytoplasts and HTC karyoplasts. As expected, such hybrids were killed by 8-azaguanine.

With techniques for the routine preparation of hybrids now available, we assayed the cells for liver-specific functions. First,

24 h	+	+
48 h	+	+
72 h	+	+
96 h	+	+

Hybrids were constructed as described in Fig. 1. All cells (hybrids, A9s and HTCs) were treated for 24 h with 10^{-5} M dexamethasone before assay. The standard assay was a modification of the procedure described by Thompson and Tomkins[7]. Briefly, monolayers of cells were washed three times with buffer (1 M potassium phosphate, *p*H 7.6, 0.2 mM pyridoxal phosphate, 0.5 mM α-ketoglutarate) and allowed to air dry for 1 h at room temperature. The enzyme was then assayed as described[7]. For heat treatment, the monolayers were first heated to 75°C for 10 min and then assayed as above. The reaction product was visualised using a Zeiss research microscope. − Indicates that no reaction product could be seen in the cells; they appeared clear; + + indicates an intense purple reaction product in the cells; + indicates a reaction which is less intense than the HTC cultures but still distinctly purple.

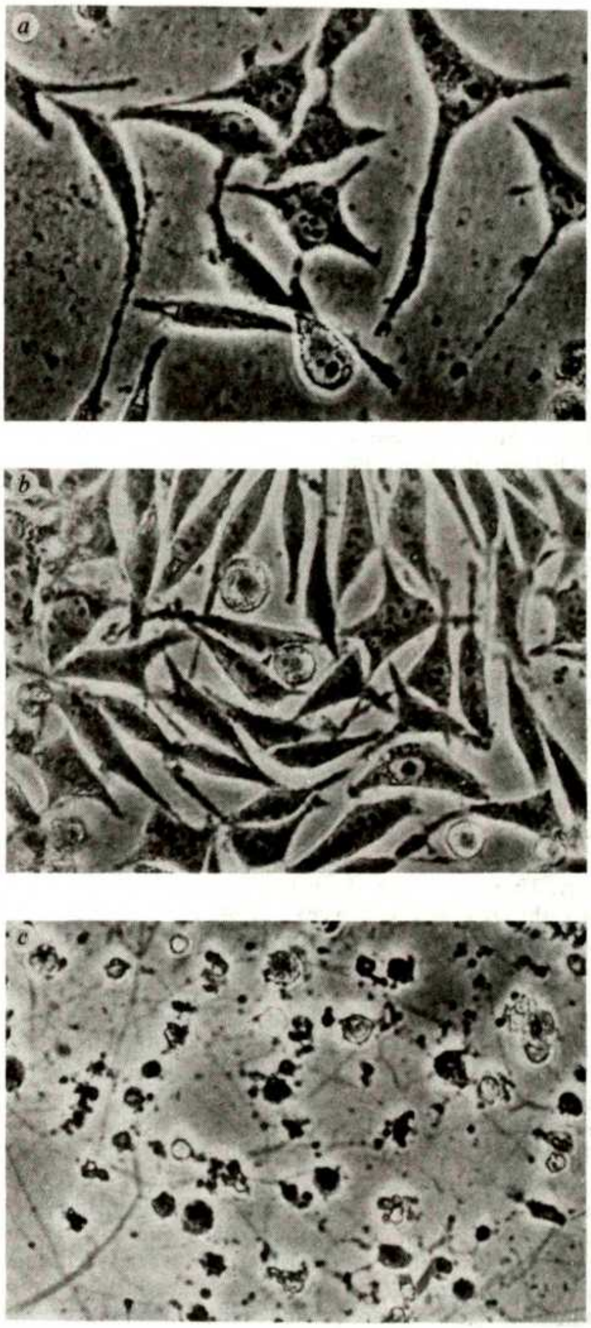

Fig. 1 Hybrid cells constructed by transplantation of mouse fibroblast A9 nuclei into rat hepatoma HTC cytoplasts. *a*, A culture at 18 h after formation; *b*, the same culture after 2 weeks of growth in azaguanine (after several subcultivations); *c*, HTC cells after 1 week in azaguanine (without subcultivation). Magnification, ×150. The A9 parent cell line was maintained in monolayers in Dulbecco's modified Eagle's medium supplemented with 10% calf serum; the HTC parent line was grown in Waymouth's MAB 87/3 supplemented with 10% fetal calf serum. Previously described techniques were adapted for cytochalasin B-induced enucleation of the A9 and HTC cell lines. Cytoplasts and karyoplasts were then fused by Sendai virus-mediated fusion as described elsewhere[3,12].

monolayer cultures were formed by transplantation of mouse fibroblast nuclei into rat hepatoma cytoplasts. At 0, 24, 48 and 72 h after fusion, a culture was incubated in dexamethasone for a further 24 h and then assayed histochemically[7] for TAT activity. Cultures of whole A9 and HTC cells were similarly treated. As noted in Table 1, HTC cells exhibited a deep purple pigmentation but A9 cells were entirely clear. Hybrid cells, at all times measured, showed an intermediate level of staining. To determine whether the reaction product seen in the hybrids was due to the mouse liver form of the enzyme, and was not merely residual rat enzyme or a non-inducible mouse pseudoenzyme, heat inactivation experiments were carried out. Both the rat TAT and mouse pseudoenzymes are considerably more thermolabile than the corresponding mouse liver enzyme. If the former enzymes are heated carefully to 75 °C for 10 min, activity is markedly reduced; mouse liver TAT, however, retains much of its activity[8]. Therefore, monolayer cultures of hybrids, A9 and HTC cells were first heated to 75 °C for 10 min and then assayed histochemically. As shown in Table 1, the appearance of reaction product in HTC cells was completely eliminated by heating. The intermediate level of response exhibited by hybrid cells was apparently unaffected. These results were obtained six times using hybrid cells constructed in separate experiments. In all the experiments presented in Table 1, cultures were treated with dexamethasone to maximise the intensity of the stain. However, in control cultures not treated with the steroid, A9 cells again exhibited no reaction product, HTC cells showed a distinctly purple but much less intense colour than induced cells, and the hybrids exhibited a barely detectable stain. It therefore seemed that the mouse enzyme produced was not only heat stable but also inducible. The magnitude of the induction was quantitated in later cultures as described below.

The observations were confirmed and quantitated using an *in vitro* biochemical assay for enzyme activity[9,10]. In these experiments, carried out on 10 separate occasions, cells were assayed at various times during the second and sixth week after fusion. As summarised in Table 2, the hybrids formed by transplantation of A9 nuclei into HTC cytoplasts exhibited levels of enzyme activity greater than 25% of that shown by induced HTC cells. Note that (1) the hybrids could be grown in the presence of azaguanine, and that (2) TAT-producing cultures were confirmed as mouse cells by karyotyping, as described above. Furthermore, the indication that the enzyme made was indeed the steroid-inducible liver form of the enzyme was confirmed by experiments showing that the enzyme produced by hybrid cells was precipitable by antiserum against purified rat liver TAT. As shown previously[8], such antiserum effectively precipitates both rat and mouse liver TATs, but not non-inducible mouse pseudoenzyme.

All the results in Table 2 were obtained from cultures between the second and sixth weeks after fusion. At earlier times it was difficult to obtain the number of hybrids needed for this biochemical assay. However, we considered it essential to assay

Table 2 Enzymatic assay of tyrosine amino transferase

Cells	Milliunits enzyme activity per 5×10^6 cells −Dexamethasone	+Dexamethasone
Mouse fibroblast A9*	1.30	1.24
Rat hepatoma HTC*	6.80	38.69
A9 nucleus–HTC cytoplasm hybrids†	3.77	10.65
HTC nucleus–A9 cytoplasm hybrids‡	Not done	45.08

Hybrids were constructed as described in Fig. 1. Assays were carried out with and without a 24-h treatment with dexamethasone (10^{-5} M). Cytoplasmic extracts prepared from cells were assayed for TAT by a modification of the Diamondstone assay[9], as described by Granner and Tomkins[10]. Assays were carried out on hybrids at various times during the second and sixth weeks after fusion.

* Data represent means of 10 separate assays.

† Data represent means obtained from 10 separate fusion experiments.

‡ Datum represents mean obtained from three separate fusion experiments.

early hybrids by the more accurate, quantitative *in vitro* assay. Therefore, 15 separate cultures of HTC cytoplasts were fused to A9 karyoplasts and pooled at 24 h after preparation. (Because of the ratio of karyoplasts to cytoplasts required to obtain maximum fusion, it was necessary to prepare A9 karyoplasts by enucleation of 128 cultures.) The steroid-induced level of activity in HTC cells was 28.4 mU per 5×10^6 cells, whereas the activity in 24-h hybrid cells was 7.6 mU per 5×10^6 cells. Three-week-old hybrids assayed at the same time yielded 6.4 mU of activity. Thus, the levels of enzyme produced were apparently similar throughout the 6 weeks of study. Furthermore, the enzyme present in these early hybrids was shown to be the heat-stable mouse liver form of the enzyme: after heat treatment which reduced the rat HTC enzyme activity to background levels (<1 mU per 5×10^6 cells), the hybrid cell enzyme retained, as predicted, 30% of its activity (see ref. 8). Also noted in Table 2 are observations that hybrids constructed by transplantation of HTC nuclei into A9 cytoplasts produced enzyme at levels comparable to those of the parent rat liver cell.

The data presented here were obtained from cells assayed up to 6 weeks after fusion. In all 10 experiments in which A9 nuclei were transplanted into HTC cytoplasts, however, the hybrids abruptly ceased making TAT between 6 and 8 weeks after fusion. The loss of activity was correlated with a transient change in morphology and death of many cells, after which the cultures continued to grow, apparently indefinitely, without detectable TAT activity. The period during which TAT was expressed represented some 75–100 cell generations. This would be sufficient to result in a greater than 10^{20}-fold dilution of cytoplasmic elements originally present in the hepatoma cytoplast donor cell.

This system, exhibiting the induction and modulation of an activity not normally expressed by the nuclear parent, is ideal for further analysis of the cytoplasmic elements capable of altering gene expression. Moreover, the induced programme of expression is apparently specific. Thus, the hybrids did not synthesise albumin, a liver-specific function not retained by HTC cells grown in culture (data not shown). We are now attempting to induce the synthesis of TAT in A9 cells by microinjection of components prepared from the cytoplasm of liver cells, using techniques we previously used to microinject cytoplasmic elements capable of inducing DNA synthesis in dormant nuclei[11]. If successful, such experiments would provide the basis for an assay system useful for the purification of the inducing substance.

We thank Maureen McLeod and John Bruno for assistance. TAT antiserum was provided by Dr Robert Ivarie. This research was supported by PHS training grant CA-09176 from the NCI, grant AI-11839 awarded to J.R.K. by the National Institute of Allergy and Infectious Diseases, and grant CA-22302 to J.J.L. by the NCI, DHEW.

Isolation by sucrose-density fractionation and cultivation *in vitro* of actinomycetes from nitrogen-fixing root nodules

Dwight Baker & John G. Torrey

Cabot Foundation for Botanical Research, Harvard University,
Petersham, Massachusetts 01366

George H. Kidd*

The Biological Laboratories, Harvard University, 16 Divinity Avenue,
Cambridge, Massachusetts 02138

The fixation of atmospheric nitrogen by actinomycete-nodulated, woody dicotyledonous plants represents a substantial contribution to the global nitrogen cycle[1], contributing especially to forested areas, wetlands, fields and disturbed sites of temperate and tropical regions[2]. The study of these nitrogen-fixing symbioses has been hampered by difficulties in isolating and culturing the microsymbionts *in vitro*. Recently, root nodule actinomycetes have been isolated by microdissection techniques and cultured *in vitro*[3,4]. We report here the isolation and culture for the first time of the actinomycetes associated with root nodules of *Elaeagnus umbellata* (Elaeagnaceae) and *Alnus viridis* ssp. *crispa* (Betulaceae) (shown in Fig. 1*a* and *b*, respectively), using a technique radically different from those used previously. For separating actinomycetes from root nodules, we have used the simple fractionation technique of sucrose-density sedimentation.

Root nodules (0.25 g fresh weight) from plants of *E. umbellata* Thunb., growing in nitrogen-free one-quarter-strength Hoagland's water culture solution[5], were surface-sterilised for 15 min in 50 ml of a 30% (v/v) solution of Clorox (5.25% NaOCl) to which one drop of Tween 20 had been added as a surfactant. The nodules were washed twice in sterile distilled water and then crushed in a sterile mortar and pestle with a small amount of sterile distilled water. The resultant slurry was filtered serially through Miracloth (Chicopee Mills) and glass wool and diluted to 10 ml with sterile distilled water.

Cellulose-nitrate centrifuge tubes were sterilised with 95% ethanol and permitted to air dry. Using heat-sterilised sucrose solutions, discontinuous density gradients were constructed of a 3-ml cushion of 60% (w/v) sucrose, a 3-ml layer of 45% (w/v) sucrose and a 6-ml layer of 30% (w/v) sucrose. Two ml of the filtered nodule suspension were layered onto each gradient, and the gradients centrifuged at 100,000*g* for 3 h at 4 °C in a Beckman L2-65B ultracentrifuge equipped with a SW-40 rotor. The gradients were fractionated by aseptically piercing the bottoms of the tubes with a 25-gauge needle and collecting eight

1-ml fractions. The sucrose-density fractions were used to inoculate agar plates of nutrient medium containing yeast extract 0.5%, dextrose 1.0%, casamino acids 0.5%, H_3BO_3 1.5 mg l^{-1}, $ZnSO_4 \cdot 7H_2O$ 1.5 mg l^{-1}, $MnSO_4 \cdot 2H_2O$ 4.5 mg l^{-1}, $NaMoO_4 \cdot 2H_2O$ 0.25 mg l^{-1}, $CuSO_4 \cdot 5H_2O$ 0.04 mg l^{-1}, vitamin B_{12} 1.6 mg l^{-1} and Difco agar 0.8%. The plates were sealed with Parafilm and incubated at 28 °C.

Colonies of a finely filamentous actinomycete appeared on the inoculation plates after approximately 3–5 weeks. The frequency of this organism in the sucrose-density fractions as demonstrated by its growth on the isolation plates was greatest in fraction 4, corresponding to the interface between the 60% and 45% sucrose layers. At 8 weeks this '*Elaeagnus* isolate' was subcultured to agar and liquid media for further observation and characterisation. The isolate grows in dense colonies composed of branching septate filaments which have diameters of approximately 0.3 μm (Fig. 1*a*). Sporangia, attached by a thickened sporangiophore, are produced terminally on the submerged filaments. Spores within the sporangia are roughly 1 μm in diameter and spherical to oblong. The *Elaeagnus* isolate will grow on the surface of agar, but true aerial mycelia or aerial sporangia are not formed. Colonies produce variable amounts of blood-red pigment that diffuses into the culture medium. We have designated the isolate *Frankia* sp. EuI1 until the uncertainty of specific epithets[6] can be resolved.

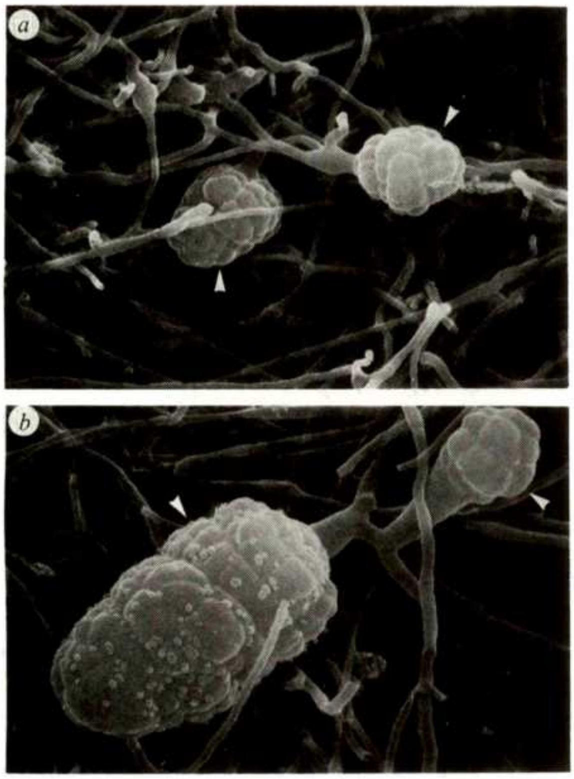

Fig. 1 Scanning electron micrographs of *in vitro* cultured actinomycete microsymbionts, ×3,550 (specimens fixed in glutaraldehyde, dehydrated in ethanol, critical-point dried with liquid CO_2 and sputter-coated with gold–palladium). *a*, Actinomycete isolated from root nodules of *E. umbellata*. Sporangia (arrows) contain many small spores. *b*, Actinomycete isolated from root nodules of *A. viridis* ssp. *crispa*. Arrows indicate sporangia.

Infectivity tests were carried out to confirm that the *Elaeagnus* isolate was in fact a symbiotic endophyte. *Elaeagnus* seedlings, germinated and grown in moist sand for 4 weeks, were transplanted into 400 ml standing water cultures supplied with Hoagland's nitrogen-free solution. The plants were grown in a controlled-environment chamber under a light–dark cycle for 16 h and 8 h, respectively, and a day–night temperature cycle of 27 °C and 21 °C, respectively. After 1 week in the nitrogen-free solution, the plants were inoculated with a small amount of washed, homogenised *Elaeagnus* isolate from 4–6-week old broth cultures. Control plants were either uninoculated or inoculated with a crushed nodule inoculum (0.3 g ground *Elaeagnus* nodules in 5 ml water).

After 4 weeks, young developing nodules were evident on many inoculated plants. Uninoculated control plants bore no nodules. At 8 weeks, plants inoculated with a crushed-nodule inoculum were beginning to recover from nitrogen starvation whereas those inoculated with the *Elaeagnus* isolate showed no signs of recovery. At this time the number of nodules per plant was counted and routine acetylene reduction tests[7] were carried out on the observed nodules to determine nitrogenase activity (Table 1). Nodules initiated by the crushed nodule inoculum exhibited acetylene reduction rates comparable to previous reduction values for other actinomycete-nodulated plant species[8]. Nodules initiated by the *Elaeagnus* isolate showed no measurable acetylene-reduction activity and were clearly ineffective.

Figure 2*a* shows the endophyte within host cells of a plant inoculated with a crushed nodule suspension. Figure 2*b* shows the endophyte within nodule cells of a plant inoculated with *Frankia* sp. EuI1. Typical vesicles seen in the nodules initiated by a crushed nodule inoculum (Fig. 2*a*) were absent in the nodules initiated by the *Elaeagnus* isolate (Fig. 2*b*).

In view of the above successful isolation, described sucrose-density fractionation procedure was repeated step-by-step using 0.5 g (fresh weight) of nodules from *Alnus viridis* ssp. *crispa* (Aiton) Turrill collected near Atikokan, Ontario, Canada. After 3 weeks of incubation, a finely filamentous actinomycete was observed growing on the agar plates inoculated with sucrose-gradient fraction 4.

Like the *Elaeagnus* isolate, the '*Alnus* isolate' grows in radial colonies composed of branching septate filaments bearing sporangia, attached by a thickened sporangiophore (Fig. 1*b*). However, unlike species EuI1, the *Alnus* isolate grows more diffusely, will not grow on the surface of agar and does not produce any pigments. Filament diameter of the *Alnus* isolate is approximately 1 μm but sporangia are much larger (20–60 μm, Fig. 1*b*) than those of the previously isolated nodule actinomycetes. Spores are slightly smaller than 1 μm. We have designated this isolate *Frankia* sp. AvcI1.

Infectivity tests were carried out using the *Alnus* isolate or a crushed nodule suspension (0.7 g ground *Alnus* nodules in 5 ml distilled water). After 10 d young developing nodules were evident on inoculated plants. Uninoculated control plants bore no nodules. At 4 weeks the number of nodules per plant was counted and acetylene reduction assays were carried out on the observed nodules (Table 1). Acetylene-reduction values of the isolate-inoculated plants were greater than those of plants inoculated with nodule suspensions. When endophyte morphology was observed by scanning electron microscopy, the

Table 1 Nodulation and acetylene reduction values for seedlings of *Elaeagnus* and *Alnus*

Treatment	No. of test plants	Plants nodulated (%)	Nodules per plant*	Acetylene reduction†
Elaeagnus, uninoculated	6	0	0	—
Elaeagnus, nodule suspension	15	87	9.9	4.7–5.0
Elaeagnus, *Frankia* sp. EuI1	30	33	6.2	0
Alnus, uninoculated	6	0	0	—
Alnus, nodule suspension	15	20	1.3	Negligible
Alnus, *Frankia* sp. AvcI1	30	100	22.7	0.46–2.68

* Values are expressed as an average computed from those plants bearing root nodules and do not include unnodulated plants.

† Values are expresed as μM ethylene per g freshweight per h; uninoculated control plants were no measured for reductin activities.

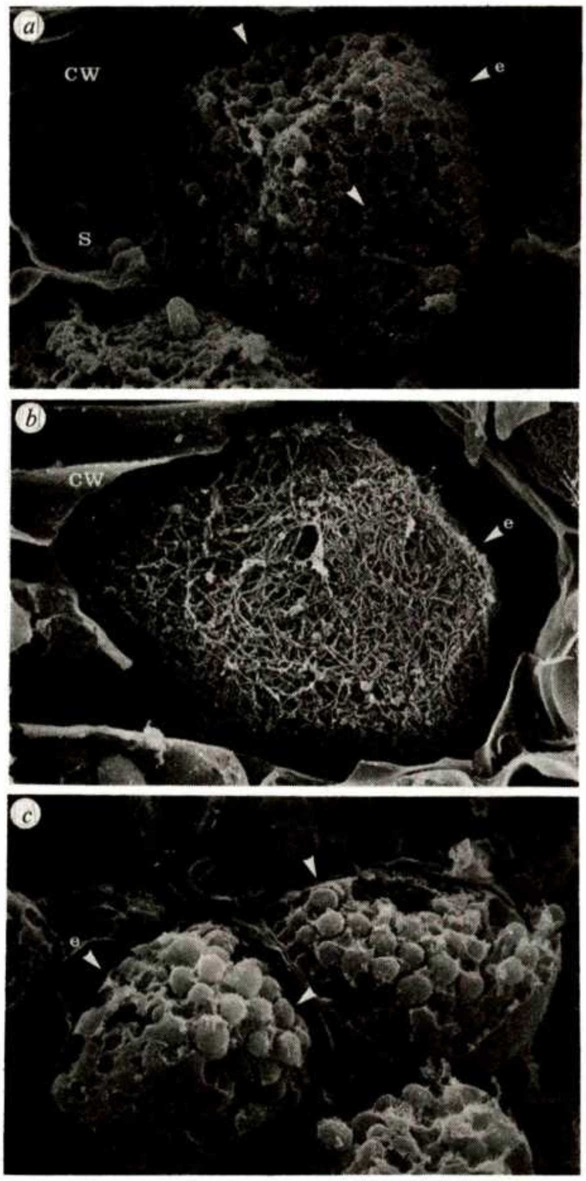

Fig. 2 Scanning electron micrographs of infected cells of host plant root nodules, ×1,100 (samples prepared as in Fig. 1); e, endophyte cluster; cw, host cell wall; s, starch grain. *a*, Actinomycete endophyte within cells of *Elaeagnus* inoculated with a crushed nodule suspension. Vesicles (small arrows) are borne terminally on mycelial branches. *b*, Actinomycete endophyte within cells of *Elaeagnus* inoculated with *Frankia* sp. EuI1. Note lack of endophytic vesicles. *c*, Actinomycete within cells of *Alnus* inoculated with *Frankia* sp. AvcI1. Vesicles (small arrows) are shown embedded in coagulated host cell cytoplasm.

nodules initiated by the *Alnus* isolate contained the vesicular endophyte typical of the *Alnus* symbiosis (Fig. 2*c*). These results suggest that the ineffective nature of the *Elaeagnus* isolate is peculiar to that organism and is not a result of the isolation procedure.

The technique described here is a relatively simple procedure for the isolation of actinomycete endophytes. The use of sucrose-density fractionation has also been applied to rhizobial–legume symbioses[9,10] and we are attempting isolations from other actinomycete-nodulated plants using this technique. Density sedimentation has proved superior to a previously used fractionation technique[11] for endophyte isolation.

The actinomycetes that we have isolated and cultured *in vitro* show a striking morphological similarity to the *Elaeagnus* and *Alnus* endophytes found in nodules of field-collected plants and each is able to reinfect the corresponding seedlings grown in water culture.

The fact that the *Elaeagnus* isolate does not form vesicles and does not reduce dinitrogen is particularly interesting in view of the postulated role of the vesicles in nitrogenase activity. Vesicles have been implicated as the site of nitrogen fixation[12] and previous research has shown that ineffective, non-vesiculate strains may exist[13]. The fact that this infective actinomycete fails to form vesicles and is incapable of fixing atmospheric nitrogen strengthens the hypothesis that the vesicle is the site of the nitrogenase enzyme.

This research was supported in part by NSF grant DEB 77-02249 and by the Maria Moors Cabot Foundation for Botanical Research, Harvard University. G.H.K. was supported by NIH multibiological sciences training grant T01-GM-00036. We thank E. Seling for assistance with scanning electron microscopy and Professor L. Bogorad for the use of his laboratory facilities.

Dual origin of recent Dutch elm disease outbreaks in Europe

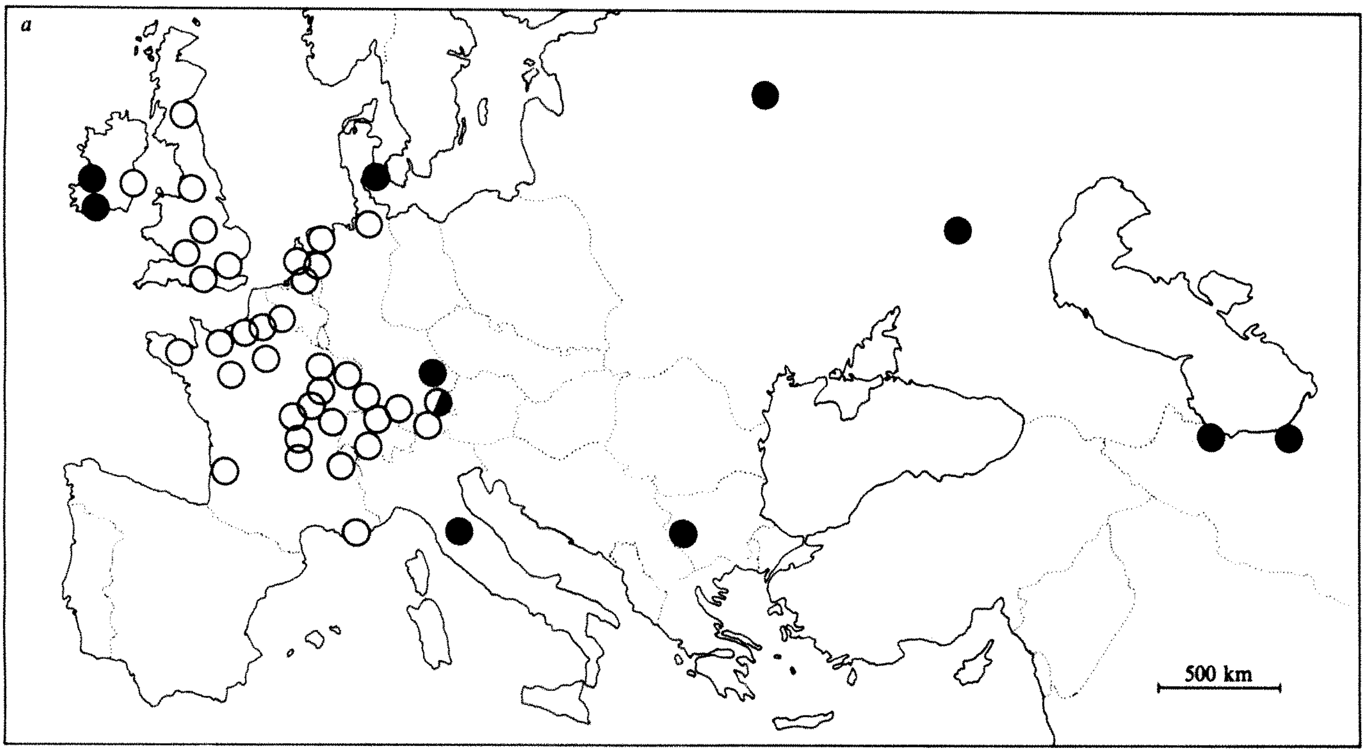
C. M. Brasier

Forest Research Station, Alice Holt Lodge, Wrecclesham, Farnham, Surrey, UK

Dutch elm disease was first recorded in 1918 in Western Europe and quickly spread to the US. The origin of the causal fungus, *Ceratocystis ulmi*, is unknown. A serious new epidemic began in the UK around 1970 and led to the discovery that there were two strains of the fungus: a highly pathogenic 'aggressive strain' responsible for the epidemic and thought to have been imported from North America[1,2], and a less pathogenic 'non-aggressive strain' believed to be endemic to the UK and adjacent parts of Europe since the 1920s (refs 1, 2). Recent disease outbreaks associated with the appearance of the aggressive strain in Holland[3] (1972), France[4,5] and Germany[6,7] (1973) were assumed to be secondary foci of the UK epidemic. A similar outbreak in Italy[7] (1973), however, seemed to be of longer standing (L. Mittemberger and O. Rackham, personal communications) and this, together with the discovery of the aggressive strain in Iran in 1975 (ref. 8), suggested that there was more than one source of the aggressive strain. I show here that there are two distinct races of the aggressive strain and that they have probably entered Europe independently.

When the colony morphologies of aggressive isolates were examined, those from the US, Canada, Holland, France and Germany were found to resemble closely UK isolates, being regular and striate, whereas those from Italy were uneven and less striate. Moreover, isolates obtained from Iran in 1975 were of the same morphological type as the Italian isolates, and a survey in 1977 confirmed the widespread occurrence of the Italian type in Iran[8].

0028–0836/79/360078—03$01.00



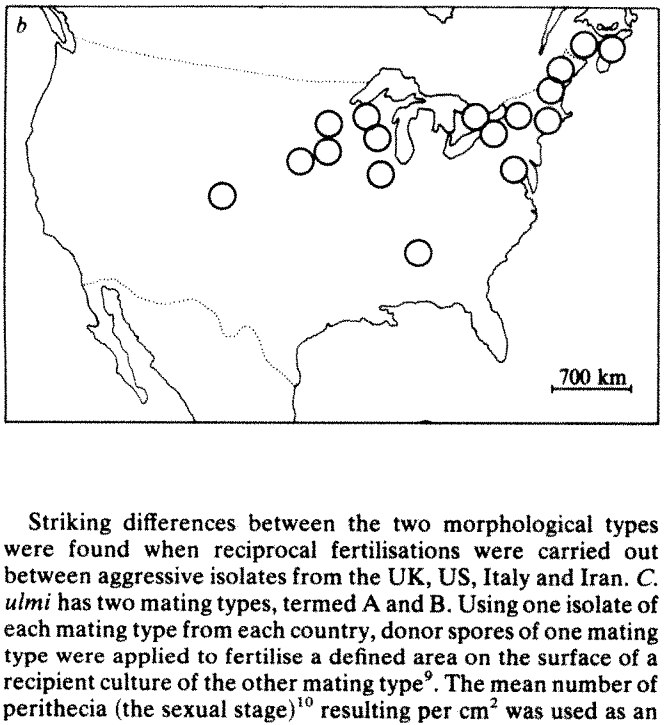


Fig. 1 Known distribution of the NAN (○) and EAN (●) races of the aggressive strain of *C. ulmi* in Europe and Asia (*a*) and North America (*b*) at the end of 1978.

Striking differences between the two morphological types were found when reciprocal fertilisations were carried out between aggressive isolates from the UK, US, Italy and Iran. *C. ulmi* has two mating types, termed A and B. Using one isolate of each mating type from each country, donor spores of one mating type were applied to fertilise a defined area on the surface of a recipient culture of the other mating type[9]. The mean number of perithecia (the sexual stage)[10] resulting per cm^2 was used as an index of the relative fertility of a given combination. The UK and US isolates were highly fertile with all donor isolates, whereas Italian and Iranian isolates showed low fertility with the UK and US isolates and high fertility with each other, the latter combinations being on average 18 times more fertile (Table 1). This indicated that the two morphological types were separate genetic entities, and they were provisionally termed the North American (NAN) and Eurasian (EAN) races of the aggressive strain.

Further samples of the aggressive strain were obtained from sites throughout North America and Europe. They included isolates from new outbreaks associated with the appearance of the aggressive strain in Ireland[11] (1977) and Denmark (1978) and isolates from the USSR and Bulgaria. Of 201 isolates examined morphologically, 127 were classified as NAN and 74 as EAN (Table 2).

To investigate the relationship between morphological type and fertility, a sample of 54 EAN and 55 NAN isolates from various countries were mated against NAN test isolates from the UK and US, and EAN test isolates from Italy and Iran. The NAN isolates again showed very low fertility against the EAN testers. All other combinations were uniformly highly fertile. The EAN × EAN (tester) combinations were on average 14 times more fertile than the NAN × EAN (tester) combinations (Table 2). Evidently, a reproductive barrier is operated unidirectionally by the EAN against the NAN isolates, a classic form of genetic isolation. The clear correlation between morphological type and relative fertility confirmed the NAN and EAN as separate genetic entities.

The NAN is the morphological type originally described in 1973 (ref. 1). The EAN differs from the NAN in having a less distinctive striate–petalloid pattern, the colonies often being lobed and uneven. In growth rate tests at 20 °C EAN isolates grow marginally more slowly than NAN isolates. Fresh EAN isolates often sector to a 'uniform powdery' (*up*) mutant, thought to be cytoplasmic in origin and the cause of their unevenness and slower growth.

That the NAN and EAN should be considered separate races within the aggressive strain rather than separate strains of *C. ulmi* is demonstrated by their similarities. In a preliminary pathogenicity test both types were highly pathogenic to *Ulmus procera*. In each, the B-mating type predominates and the rarer A-type characteristically produces protoperithecia on malt agar[8–10]. Both exhibit the unusual phenomenon of pseudoselfing[10]; both show extensive genetic isolation from the non-aggressive strain (refs 9 and 12 and C.M.B., unpublished); both have an optimum temperature for growth of ~20–22 °C compared with ~30 °C for the non-aggressive strain (J. Lea and C.M.B., unpublished).

As Fig. 1 shows, US, Canadian, UK, French, Dutch, Austrian and Swiss isolates are exclusively of the NAN race whereas Italian, Danish, Bulgarian, USSR and Iranian isolates are

Table 1 Frequency of perithecia (mean per cm^2) in inter-fertility tests of aggressive isolates of *C. ulmi* from the UK, US, Italy and Iran

		B-type donor isolates				*t*-tests for differences between means of UK and US against Italy and Iran
		UK	US	Italy	Iran	
A-type recipent isolates	UK	451	387	381	423	NS

	Italy	*3*	*0*	56	41	†
	Iran	*75*	*29*	246	305	*
		A-type donor isolates				
		UK	US	Italy	Iran	
B-type recipeient isolates	UK	198	281	239	284	NS
	US	43	24	30	32	NS
	Italy	*115*	*55*	357	368	*
	Iran	*32*	*5*	309	251	†

The experiment was carried out on elm sapwood agar. Each figure is the mean of four replicates. Student *t*-tests were carried out on replicate data transformed to square roots; significance levels: NS, not significant; * $P = <0.01$; † $P = <0.001$.

exclusively EAN. With the exception of Ireland, therefore, NAN shows a distinctly westerly and EAN a distinctly easterly distribution, both races occurring at Rosenheim in south-east Germany (5 EAN and 5 NAN in a sample of 10 isolates in August 1978).

On this evidence I suggest that the recent outbreaks of Dutch elm disease in Western Europe are of dual origin: through the importation of the NAN race of the aggressive strain from North America into the UK in the late 1960s (ref. 2), and into France, Holland and Germany, probably via Britain, in the early 1970s; and through migration of the EAN race from Italy, from central Europe or from farther east.

The Irish outbreak of 1977 is particularly interesting. The NAN isolates came from the Dublin area, whereas the EAN isolates all came from the Limerick–Cork area in the south-west. The Dublin and Limerick outbreaks were thought by Walsh and Mangan[11] to have originated independently, and the geographical distribution of the two races seems to confirm this. It would be intriguing to know the origins of these outbreaks. The Danish outbreak of 1978 is so far confined to Odense on the island of Funen, and because it is caused by the EAN race is probably due to importation of diseased material from the south or east. These events indicate that had the aggressive strain not reached the UK in the form of the NAN race from North America, it would probably have eventually arrived in the form of the EAN race from south or central Europe.

Table 2 Separation of aggressive isolates of *C. ulmi* into the NAN and EAN morphological types, and results of fertility tests against a recipent EAN isolate

	Morphological type			Fertility tests against EAN isolate* Mean perithecia per cm^2	
Country	No. of isolates examined	No. of NAN	No. of EAN	NAN isolates (no. of isolates tested)	EAN isolates
Austria	2	2	—	3.5(2)	—

UK	(>4,000)	(>4,000)	—	4.0(8)	—
			Mean	3.6(55)	50.6(54)

* Isolates were from twig samples from individual diseased trees with the exception of two from the USSR which were bark isolates. Over 4,000 twig and bark isolates have been examined in the UK since 1972.

† The recipient EAN isolate used as a standard was Iranian isolate AST 20 ('A' mating type). All isolates tested against it were 'B' mating type. The data are from five separate experiments carried out on elm sapwood agar.

Further surveys of the fungus are now required in Europe and Asia, in particular Siberia, the Himalayas and China. These are the main sources of resistant elm material and somewhere in this region may be the centre of origin of *C. ulmi*. The full extent of variation in the fungus needs to be determined as soon as possible for the purposes of breeding resistant elms. Promising elm material should now be screened with both races of the aggressive strain.

I thank Maxine Rawlings for technical assistance, and many colleagues abroad for sending samples of *C. ulmi*.

Energy dependence and reversibility of membrane alterations induced by polyene macrolide antibiotics in *Chlorella vulgaris*

Barbara Malewicz & Edward Borowski

Department of Pharmaceutical Technology and Biochemistry, Technical University, Gdańsk and Institute of Oceanology, Polish Academy of Science, Poland

The requirement of metabolic energy for the interaction of polyene macrolide antibiotics with eukaryotic organisms remains a controversial subject (for review see ref. 1). It has been claimed that the lethal binding of these antibiotics to the sterol target component of the hydrophobic core of the membrane, in accordance with the model of de Kruijff and Demel[2], is an energy-dependent process. When energy production is reduced by removal of all metabolisable substrates or by adding metabolic inhibitors, polyene binding and antifungal effects are also reduced. Metabolic energy may be required to maintain binding site accessibility or to move antibiotic molecules to the active site. The interaction is also restricted at low temperatures, possibly because of the reduced thermal mobilities of the groups concerned with antibiotic uptake. However, it should be emphasised that the interaction of polyene macrolides with artificial lipid membranes is a purely physicochemical process, although the type of permeability pathways induced are similar to those observed in natural membranes[1]. Using *Chlorella vulgaris* as a model organism, we demonstrate here that the interaction of polyene macrolides with sensitive cells and the induction of lethal membrane permeability changes are energy-dependent processes or purely physicochemical phenomena, depending on the structure of the antibiotic used.

As *C. vulgaris* is an autotrophic aerobic organism, energy production can be controlled naturally by changing the availability of light and oxygen, thus eliminating the need to use

0028-0836/79/360080—03$01.00

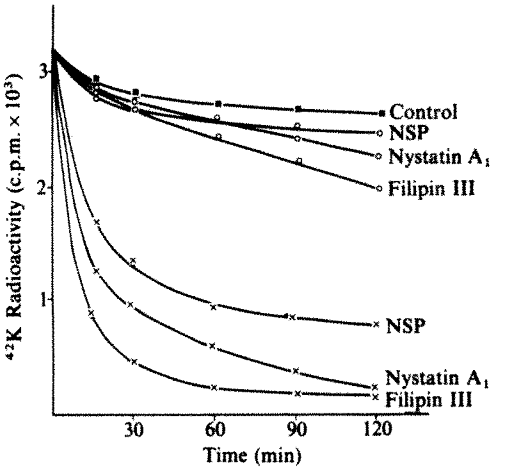

Fig. 1 The influence of temperature on the leakage of potassium from *C. vulgaris* on treatment with filipin III (30 μg ml^{-1}), nystatin A$_1$ (10 μg ml^{-1}) and *N*-succinylperimysin (NSP) (25 μg ml^{-1}). ^{42}K-labelled *C. vulgaris* cells (3 mg ml^{-1}) were suspended in Tris-HCl buffer, *p*H 7.2, at 0 °C (○) or 30 °C (×), and 0.1-ml samples of antibiotic solution in dimethyl sulphoxide (DMSO) added. The suspensions were aerated by shaking and illuminated. Aliquots were taken, cells filtered and washed with ice water and their radioactivity recorded.

chemical inhibitors which are not usually very specific. In anaerobic conditions and in the absence of light, ATP production in *Chlorella* spp. is completely inhibited[3]. The presence of ergosterol in the cytoplasmic membrane[4] makes this organism sensitive to the action of polyene macrolides[5,6].

In this study we have used compounds which represent possible different types of interaction with *C. vulgaris*, based on the reversibility of the lethal action of polyene macrolides on this organism. Following our observation on the reversibility of fungicidal action of a polyene macrolide[7], we have demonstrated that the ability of *C. vulgaris* cells to repair antibiotic-induced damage[6] depends on the structure of these antibiotics. Small macrolide ring polyenes (for example, filipin III) act irreversibly, whereas the action of those with a large macrolide ring but with low unsaturation in the chromophore (for example, nystatin A$_1$) can be reversed after brief contact with cells but not after prolonged exposure. Compounds with a large macrolide ring and a heptaenic chromophore (for example, *N*-succinylperimycin) induce repairable membrane alterations, and their lethal action can be fully reversed after removal of the antibiotic from the medium, regardless of the time of exposure.

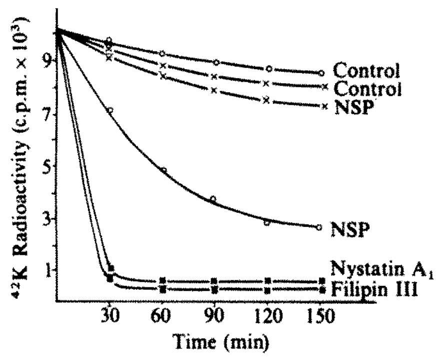

Fig. 2 The influence of the metabolic inhibitor, CCCP, on the potassium leakage from *C. vulgaris* treated with filipin III (50 μg ml^{-1}), nystatin A$_1$ (20 μg ml^{-1}) and *N*-succinylperimycin (NSP) (25 μg ml^{-1}). ^{42}K-labelled *C. vulgaris* cells (3 mg ml^{-1}) were suspended in Tris-HCl buffer *p*H 7.2, at 30 °C and preincubated with (×) and without (○) 5×10^{-5} M CCCP for 30 min with shaking and illumination, followed by the addition of antibiotics in 0.1 ml DMSO. Aliquots were taken, cells filtered and washed with ice water and their radioactivity recorded.

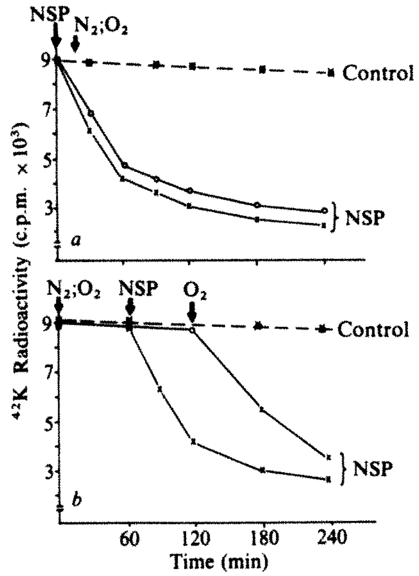

Fig. 3 The influence of light and oxygen on potassium leakage from *C. vulgaris* on treatment with *N*-succinylperimycin (NSP) (25 μg ml^{-1}). ^{42}K-labelled *C. vulgaris* cells (3 mg ml^{-1}) were suspended in Tris-HCl buffer, *p*H 7.2, at 30 °C. *a*, The suspension was aerated by shaking and illuminated, then a 0.1-ml solution of NSP in DMSO added. After 15 min, nitrogen was passed through the suspension in the dark (○) or the culture was kept in the light and aerated (×). Aliquots were taken, the cells filtered, washed with ice water and dried, and their radioactivity recorded. *b*, The suspension was kept in nitrogen in the dark, with shaking, or aerated under illumination. After 1 h NSP, 25 μg ml^{-1}, in 0.1 ml DMSO was added to both suspensions. After another hour, air was introduced to the anaerobic suspension and the suspension was shaken and illuminated. Aliquots were taken from both suspensions, the cells filtered, washed with ice water and dried, and their radioactivity recorded. ○, N$_2$; ×, O$_2$.

The interaction between the compounds examined and *C. vulgaris* was followed by measuring the leakage of potassium ions. The discharge of the gradient of this marker ion may be regarded as one of the first indications of membrane damage[8]. Filipin III[9], nystatin A$_1$ (ref. 10) and *N*-succinylperimycin[11,12] induce potassium leakage only at elevated temperatures (Fig. 1). In these conditions the use of the metabolic inhibitor carbonyl cyanide *m*-cholorophenylhydrazone (CCCP) does not prevent the interaction of filipin III and nystatin A$_1$ with *C. vulgaris*, but strongly inhibits the activity of *N*-succinylperimycin (Fig. 2). The leakage of potassium from cells treated with filipin III and nystatin A$_1$, in the presence of CCCP, indicates that the interaction of these antibiotics with the plasma membrane of *C. vulgaris* is a physicochemical phenomenon, not an energy-dependent process. The energy dependence of the interaction of *N*-succinylperimycin with the membrane was further confirmed by changing the availability of light and oxygen (Fig. 3). Whether the cells were treated with *N*-succinylperimycin in aerobic conditions and after 20 min nitrogen passed through the suspension in the dark, or whether the culture was aerated in the light, the potassium efflux was practically identical (Fig. 3*a*). This indicates that once *N*-succinylperimycin has reacted it induces a permeability pathway for potassium, effective in the presence or absence of metabolic energy. On the other hand, when the suspension was well washed with nitrogen and kept in the dark before the addition of

N-succinylperimycin, no potassium leakage occurred even after a 1-h exposure to the antibiotic. The subsequent introduction of oxygen and illumination caused rapid discharge of the potassium gradient, similar to that seen when the antibiotic was added in aerobic conditions (Fig. 3*b*). This experiment clearly shows the requirement of metabolic energy for the induction by *N*-succinylperimycin of a potassium permeability pathway in *C. vulgaris*.

We conclude that the polyenes examined which induce irreversible membrane permeability changes in *C. vulgaris* (filipin III and nystatin A_1) interact with the membrane in a physicochemical manner. On the other hand, the compound whose lethal action can be reversed and the induced membrane damage repaired (*N*-succinylperimycin) requires metabolic energy for its interaction with the plasma membrane.

Our findings indicate that the formation of various types of membrane structures can be induced by polyene macrolides, depending on the structure of the antibiotic. Although very little is known about the structures created in biological membranes by polyene macrolides, hypothetical molecular models have suggested that bulky polyene–sterol complexes, half pores, or conductance channels can be formed on interaction of various polyene macrolides with sterol-containing lipid bilayers[2]. It is reasonable to assume that only the formation of a highly specific membrane structure, namely, the ion-selective conductance channel, requires metabolic energy. The formation of ion-specific channels by *N*-succinylperimycin is indicated by the complete reversal of its killing action in a medium containing an isotonic concentration of potassium salts, added to prevent death through lack of potassium[6,7].

Ionophore A23187 disrupts membrane structure by modifying protein–lipid interactions

Richard D. Klausner, Mark C. Fishman & Morris J. Karnovsky

Departments of Medicine and Pathology, Harvard Medical School,
Boston, Massachusetts 02115

The physiological function of membrane-bound protein clearly depends on the nature of its neighbouring lipid[1]. However, the question of how critical the protein is to the structure and function of membrane lipid has received much less attention. There is some evidence that lipid surrounding membrane protein, 'boundary lipid', may be more ordered than continuum lipid[2]. Protein can also alter the enthalpy and temperature of pure lipid-phase transitions[3]. However, controversy surrounds the question of whether membrane proteins determine long-range aspects of lipid structure or merely perturb their local environments[4,5]. Here, we demonstrate that a lipophilic substance, the calcium ionophore, A23187 (Lilly), dramatically disorders the lipid structure of the membrane and that this phenomenon depends on the presence of proteins.

We used the polyene fluorescent probe, 1,6-diphenyl-1-3-5-hexatriene (DPH), to measure membrane lipid order[6]. Steady-state fluorescence polarisation was measured with an SLM model 4800 fluorescent phase modulation lifetime machine[7]. All measurements were corrected for scatter. Lifetime measurements were made with the same machine. Fluorescence spectra were obtained with a Perkin-Elmer model MPF-2a spectrophotometer. The probe was incorporated into cells (fresh splenic mouse lymphocytes, BHK or 3T3 cells grown in culture) and multilamellar lipid vesicles as previously described[8]. Vesicles were prepared from lipid extracts of cell membranes[9] or with purified phospholipids (Sigma). Purified (Na^+ + K^+)ATPase (Sigma) was reconstituted into lipid vesicles by solubilising both lipid and protein at a 10:1 (w/w) ratio in 10 mM Tris, 120 mM NaCl and 5% Na deoxycholate (DOC). The DOC was removed by dialysis for 72 h. Spectral analysis revealed that about 25% of the original protein could be incorporated into the resulting vesicles. Freeze-fracture electron microscopy of the reconstituted vesicles showed many intramembranous particles.

Figure 1 shows the dramatic DPH polarisation changes in lymphocytes as a function of the concentration of A23187. They suggest marked alterations in lipid packing due to the ionophore. The *P* value change occurred within 30 s and was not affected by the addition of EGTA or alteration of the concentrations of Ca^{2+} or Mg^{2+}. It was not inhibited by 10 $\mu g\ ml^{-1}$ of cytochalasin B, 10^{-6} M colchicine or 10^{-3} M NaN_3. The effect persisted despite washing and resuspending the treated cells, and was not abolished by heating the cells to 65°C for 15 min. This dose-dependent lowering of the *P* value was seen with all cell types tested. However, these polarisation changes were not found in pure lipid systems (even at 10^{-4} M A23187). Thus, as shown in Table 1, A23187 did not affect the *P* value of DPH-labelled liposomes. Reconstituted vesicles, on the other hand, containing protein and lipid, exhibited a diminution in DPH polarisation comparable to that of whole cell membranes.

Spectral analysis showed that there was no alteration in DPH excitation or emission spectra produced by the ionophore. Fluorescence lifetimes of DPH in cell membranes were measured. These were unaltered in the presence of the ionophore, indicating that the steady-state polarisation changes reflect true alterations in the rotational correlation times of the probe.

It surprised us that this lipophilic drug required protein to exert its 'fluidising' effect on membrane lipids. It is possible that the drug binds to proteins, decreasing the overall probe polarisation by displacing 'rigid' boundary lipid. However, extraction of membrane proteins and hence of boundary lipid results in only a 20% dimunition in DPH polarisation (Table I). This is

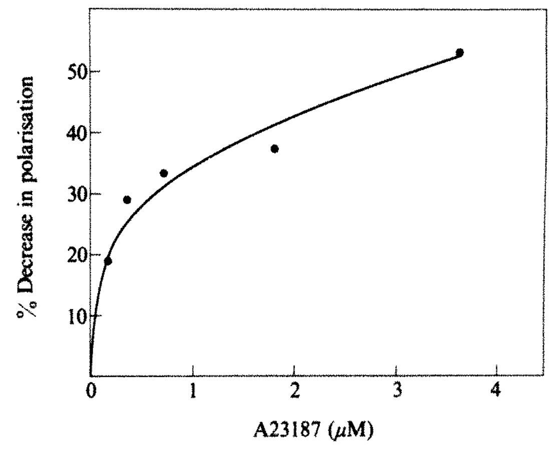

Fig. 1 Percentage decrease in polarisation of DPH as a function of the concentration of A23187 added to lymphocyte membranes. Baseline polarisation is 0.268 ± 0.012 (s.e.m.)

0028-0836/79/360082—02$01.00

Table 1 The effect of A23187 on DPH polarisation

Lipid	*P* Value	
	Control	+A23187
Phosphatidylcholine dimyristoyl		
4°C	0.440 ± 0.006	0.438 ± 0.005 (1 μM)
23°C	0.254 ± 0.014	0.250 ± 0.011 (1μM)
30°C	0.160 ± 0.008	0.160 ± 0.006 (1 μM)
Liposomes from:		
Lymphocytes	0.252 ± 0.012	0.250 ± 0.008 (1 μM)
BHK cells	0.268 ± 0.010	0.276 ± 0.006 (1 μM)
Liposomes reconstituted with ($Na^+ + K^+$)ATPase		
Lymphocytes	0.304 ± 0.018	0.220 ± 0.028 (0.72 μM) 0.178 ± 0.040 (1.44 μM)
BHK cells	0.280 ± 0.022	0.245 ± 0.020 (0.72 μM) 0.220 ± 0.019 (1.44 μM)

Polarisation of DPH in pure phosphatidyl choline vesicles above, at and below the phase transition is not altered by the addition of A23187. Liposomes made from lipid extracts of lymphocytes or BHK cells and tested at 23°C also seem to be unperturbed by the ionophore. Vesicles reconstituted with ($Na^+ + K^+$)ATPase show dose-dependent alterations in DPH polarisation with A23187. Values given as mean and s.e.m.

much smaller than the change induced by A23187. Thus, we consider this explanation unlikely. It is more likely that the ionophore can exert its disordering influence only when the lipids are in specific configurations. Thus, perhaps pure lipids cannot assume such structure, but the insertion of proteins reorganises the lipids into appropriate configurations. Analogies exist: for example, chlorpromazine alters lipid structure, but only in the presence of appropriate cholesterol content[10].

The nature of this special lipid configuration is unclear. However, it is unlikely to be simply the gel or liquid crystalline phases, because no effect is seen in pure phosphatidylcholine dimyristoyl vesicles either above or below the endothermic phase transition. Where does the ionophore act? One possibility is, at the lipid protein boundary. A23187 binds to both lipids and proteins[11] and may well have particular affinity for the lipid–protein interface. At the lipid–protein boundary it would not act to displace boundary lipid but to alter the nature of the lipid ordering effects exerted by the membrane protein. The magnitude of our results suggests that the effect of protein on the lipid, at least by means of a perturbing molecule, can be large.

This research was supported by grants AI-10677, HL-09125 and CA-14723 from the NIH, USPHS.

An incipient 3_{10} helix in Piv-Pro-Pro-Ala-NHMe as a model for peptide folding

Y. V. Venkatachalapathi & P. Balaram

Molecular Biophysics Unit, Indian Institute of Science,
Bangalore 560 012, India

The molecular mechanism of helix nucleation in peptides and proteins is not yet understood and the question of whether sharp turns in the polypeptide backbone serve as nuclei for protein folding has evoked controversy[1,2]. A recent study of the conformation of a tetrapeptide containing the stereochemically constrained residue α-aminoisobutyric acid, both in solution and the solid state, yielded a structure consisting of two consecutive β-turns, leading to an incipient 3_{10} helical conformation[3,4]. This led us to speculate that specific tri- and tetrapeptide sequences may indeed provide a helical twist to the amino-terminal segment of helical regions in proteins and provide a nucleation site for further propagation. The transformation from a 3_{10} helical structure to an α-helix should be facile and requires only small changes in the φ and ψ conformational angles and a rearrangement of the hydrogen bonding pattern[5]. If such a mechanism is involved then it should be possible to isolate an incipient 3_{10} helical conformation in a tripeptide amide or tetrapeptide sequence, based purely on the driving force derived from short-range interactions. We have synthesised and studied the model peptide pivaloyl-Pro-Pro-Ala-NHMe (compound I) and provide here spectroscopic evidence for a 3_{10} helical conformation in compound I.

The choice of the pivaloyl blocking group at the amino-terminal was dictated by the necessity of maintaining the first amide bond in a *trans* configuration. While X-Pro bonds can exist in both *cis* and *trans* configurations in solution[6], the bulky tertiary butyl group locks the piv–Pro bond into the *trans* structure[7]. ^{13}C NMR studies, of a number of pivaloyl-Pro containing peptides, show no evidence for the presence of the *cis* isomer (unpublished observations). The Pro-Pro-Ala sequence was chosen because of the strong tendency of Pro-X sequences to form β-turns[8], a consequence of the restriction of the φ angle in the pyrrolidine ring to ~ −60°. The carboxyl terminal was converted to the methylamide to provide the NH group necessary for stabilising the second β-turn by formation of an intramolecular 4 ← 1 hydrogen bond.

Figure 1*a* and *b* shows the 270 MHz ^1H and 67.89 MHz ^{13}C NMR spectra of I in $CDCl_3$. It is clear from both spectra that of the four possible isomers about the pivaloyl-Pro and Pro-Pro bonds (*trans–trans, trans–cis, cis–trans* and *cis–cis*) only one is present in solution. The chemical shifts of the C^β and C^γ resonances of both Pro residues (Table 1) fall within the range expected for *trans* X-Pro bonds[9], suggesting that both the pivaloyl-Pro and Pro-Pro bonds are exclusively *trans*. The effect of changing temperature and solvent on the chemical shifts of the Ala and methylamide NH groups, are summarised in Table 1. Both amide hydrogens show a very small temperature coefficient in $(CD_3)_2SO$ and almost no change in chemical shift on going from a poor hydrogen accepting solvent, such as $CDCl_3$, to a good acceptor, such as $(CD_3)_2SO$.

These results provide clear evidence that both NH groups in the molecule are shielded from the solvent[9]. The IR spectrum of I in dilute $CHCl_3$ solution shows the presence of only one N–H stretching band at 3,340 cm^{-1}, demonstrating that the NH groups are involved in the formation of intramolecular hydrogen bonds. The lack of a band at ~3,430 cm^{-1} suggests that conformations with free NH groups are absent. Figure 2 shows a possible conformation of compound I with the Ala and methylamide NH groups involved in 4 ← 1 intramolecular hydrogen bonds. While the available data only provide evidence for the participation of NH groups in hydrogen bonds, we propose the consecutive β-turn structure taking into account the known propensity of Pro residues to initiate β-turns[8]. Indeed the absence of a free NH stretching band at ~3,450 cm^{-1} argues for

an almost exclusive preference for the highly folded incipient 3_{10} helical structure shown in Fig. 2. The observed $J_{NH\text{-}C^\alpha H}$ values of 9.2 Hz and 8.9 Hz in $CDCl_3$ and $(CD_3)_2SO$ for the Ala NH are compatible with a ϕ value of $\sim -80°$ for the Ala residue[10]. The presence of two Pro residues with $\phi_{Pro} \sim -60°$ and the constraints of two intramolecular $4 \leftarrow 1$ hydrogen bonds suggested that ψ_{Pro} values[11] are likely to be restricted to the range $-20°$ to $-40°$. These values are very close to those expected theoretically in a 3_{10} helix ($\phi \sim -60°$, $\psi \sim -30°$).

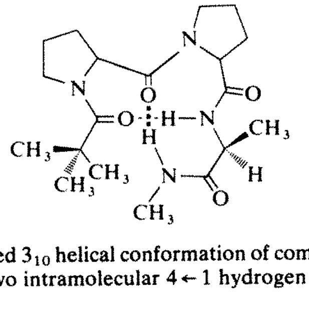

Fig. 2 Proposed 3_{10} helical conformation of compound I showing the two intramolecular $4 \leftarrow 1$ hydrogen bonds.

The importance of the methylamide NH group in stabilising this folded structure is emphasised by the fact that in the related compound pivaloyl-Pro-Pro-Ala-OCH_3, the presence of three conformers in the ratio 37 : 28 : 35 can be detected by 270 MHz ^1H NMR in $CDCl_3$. Further, the Ala $J_{NH\text{-}C^\alpha H}$ values of 7.3, 7.7 and 7.0 Hz in the three species reflect conformational averaging over the Ala N–C^α bond and may be contrasted with the J value obtained for I.

The above results provide direct evidence of a 3_{10} helical structure in a tetrapeptide containing some amino acids that occur frequently in proteins. In view of the frequent observation of 3_{10} helical segments at the ends of α-helical regions in protein crystal structures[12], it seems that consecutive β-turn structures have a definite role in giving the polypeptide chain a helical twist. In particular, peptide sequences containing a cluster of residues with a strong tendency to occur in β-turns, like Pro, Gly, Asn, Asp, Ser and Cys[13], may have an important role in forming 3_{10} helical segments. Experimental tests of this hypothesis are under way.

We thank Ch. Pulla Rao for recording the IR spectrum and the University Grants Commission, India, for financial support.

Corrigendum

In the letter 'Parity nonconservation and stellar collapse' by A. Vilenkin, *Nature* **280,** 569–570 it was argued that the direction dependence of the neutrino mean free time in a magnetic field **B** gives rise to a neutrino energy flux parallel to **B**. However, it can be shown from the Boltzmann equation that scattering reactions ($\mathbf{p}r, \mathbf{q} \rightarrow p'r', q'$) and ($\mathbf{p}'r', \mathbf{q}' \rightarrow \mathbf{p}r, \mathbf{q}$) where **p** and **q** are electron and neutrino momenta and *r* is electron spin, balance in such a way that the net result is zero; that is, there is no neutrino energy flux in a magnetic field. The author thanks Ch. G. Van Weert and L. van den Horn for a discussion which helped to reveal the error.

Macromolecules

Such is the importance of Macromolecules that an entire double issue of **BIO SYSTEMS** has been devoted to this subject. The Special Issue will be published during August under the title of **Macromolecules and the Evolution of Information Processing** and a limited number will be available as single copies.

Because of the highly relevant and interesting papers presented in this Special Issue, **Macromolecules and the Evolution of Information Processing** will form a valuable reference work for all scientists working in this field.

Scientific Models and Man

The Herbert Spencer Lectures, 1976

Edited by Henry Harris

In these lectures, a group of distinguished men from different disciplines describe how current work in their own subject is changing their view of the world. Scientific models have been enormously influential in transforming the way in which we look at ourselves and the universe in which we live. While the transformations produced by Newton, Harvey, Darwin, and Einstein are now familiar, contemporary intellectual revolutions are less easy to appreciate, since they take time to make their full influence felt. This book gives some indication of the way the world is going to look tomorrow. Illustrated £5.95

Electronic Processes in Non-Crystalline Materials

Sir Nevill Mott and E. A. Davis

Since the first edition of this book there has been great development both in the experimental and theoretical studies of the electrical properties of non-crystalline solids, so that it has been necessary to rewrite almost the whole of the book. The aims of the new edition, however, remain the same: to set out the theoretical concepts, to test them by comparison with experiment for a wide variety of phenomena, and to apply them to non-crystalline materials. Sir Nevill Mott shared the 1977 Nobel Prize for Physics, awarded for his research in this field. Second edition £29 *International Series of Monographs on Physics*

Auditory Investigations

The Scientific and Technological Basis

Edited by H. A. Beagley

Interest in the science of hearing is growing steadily and audiological medicine is now a recognized medical speciality. This book is intended for the wide and increasing body of professionals who are concerned with otology, audiological medicine, and audiological science: audiologists; physiologists specializing in the auditory system; otological surgeons; audiological physicians; and medical physicists, especially those reading for a Master's degree in audiology. Subjects covered include the inner ear mechanism, the sound transducer and frequency analyser action of the cochlea, the mechanoneural transduction which occurs in the cochlea, and the mechanism of the neural pathways involved in audition. Illustrated £35 *Oxford Medical Engineering Series*

reviews

Science policy in the developing world

Ziauddin Sardar

Science, Technology and Development: Essays in Honour of A. Rahman. Edited by K.D. Sharma and M.A. Qureshi. Pp. 478. (Sterling Publishers: New Delhi, 1978.) Rs 120.

THIS anthology of papers on the themes of science policy, science and society, technology assessment, technology and underdevelopment, research management and science in India is a fitting tribute to Professor A. Rahman, "whose pioneering work", in the words of J. J. Soloman, "in science policy studies related to the problems of development has been outstanding". The idea of honouring a Third World scientist who has made a varied and sustained contribution to knowledge is indeed appropriate and thee must certainly be others who would have liked to be associated with it.

Science, Technology and Development opens with a brief biographical sketch of A. Rahman. Rahman was educated at the Aligorh Muslim University and in England where he studied biochemistry under the Noble Laureate H.A. Cripps and came in contact with such scholars of the left as J.D. Bernal, Joseph Needham, J.B.S. Haldane and H. Levy. Their influence has obviously left its mark on his thinking and is responsible for his switch from biochemistry to the history and social philosophy of science. Rahman's distinguished career in the Council of Scientific and Industrial Research (CSIR) began at Regional Research Laboratory in Hyderabad immediately after his return from England. Since then he has served in many CSIR laboratories, moving, in 1963, to CSIR Headquarters in New Delhi to organise an information centre and to develop a systems approach to planning and resource allocation for the various laboratories of CSIR. Currently, he is Chief of Planning at CSIR and leads the Centre for the Study of Science, Technology and Development.

There are 26 papers in this presentation volume, inevitably of uneven quality. Some of the essays (for example, J. J. Soloman on "Science Policy and Social Objectives", E. B. Skolnikoff on "The Governability of Complexity", A. H. Rubenstein, T. W. Schlie and A. D. Jedlicka on "Some Current Field of Research on "Appropriate Technologies for the Less Developed Countries" and S. R. Mikulinsky on "The Present State and Problems of the History of Natural Science") seem to be positively dated, some others (for example, Y. de Hemptine on "Integrated versus Sectoral Policies for Science and Technology", Jozef Bognar on "Culture, Science and Economy" and D. de Solla Price on "India as a Small Highly Developed Scientific Nation") are in the nature of fragments only; but, on the whole, there is enough thought provoking material here for the volume to be valuable to both the students and researchers of the social relations of science and technology.

The volume is at its strongest when dealing with science and technological policy in India. In a commanding analysis, A. K. N. Reddkly argues for the generation of environmentally sound and appropriate technolgies for rural development. His strategy is based on two components: forging strong links between the educational, scientific and technological institutions and the needs of the rural poor and their traditional technologies, on the one hand, and drastically weakening the reliance of these institutions on elitist demands and on institutions in the developed world. A strategy after my own heart, and one that C. Subramaniam shows so convincingly is bound to be fruitful.

Subramaniam describes a rural strategy developed for Karimnager, "a backward district of Andhra Pradesh". The work in Karimnager began with an assessment of soil, geohydrological and forest resources, an assessment of human potential, identification of new irrigation wells and a determination of fertilizer doses, and proceed to the planning of feeder roads and housing colonies based on techniques that emphasise maximum use of local material and skills. A windmill was designed and built for lifting water from the only source of drinking water in the village, carried out with the help of the National Aeronautical Laboratory, "which till then used to interest itself in nothing less lowly than designing and testing aeronautical systems for jet aircrafts". Other projects developed for Karimnager included the collections of all waste material — human, animal and agricultural — to be processed in an inexpensive biogas plant to produce domestic fuel and fertiliser, the substitution of rubber-roller type of shellers for the more conventional energy: sheller in rice processing equipment, and improvement of various techniques from bee-keeping, making palm-candy to tanning and securing a better extraction of fibre from banana and sisal. Karimnager, K. Subramaniam argues forcefully, is a shining example of what can be achieved when scientists turn their attention to the needs of the rural poor.

India is saturated with Karimnagers and it is reasonable to assume that this success story will be repeated elsewhere. Indeed, as K. D. Sharma and M. A. Qureshi argue in their contribution, "A Framework for Alternative Technology", India needs to develop a mix of "traditional small and big technologies to achieve composite development so as to strike a balance between the internal socio-economic situation and external plolitical stability". Although "national prestige" and "national security" figure large in their thinking, Sharma and Qureshi are really arguing for an upgrading of traditional technologies and a little more scrutiny of high technology projects. There is little doubt that India cannot tolerate, as Ward Morehouse shows in his richly detailed study of "Scuttling the Coal Gasification Project at Hyderabad: The Perils of Public Patronage in Bridging the Development Gap", a situation where its science is unwittingly pushed forward in large, prestigous undertakings. Scientists like Rahman, who turn their attention from the glare of prestige science and high technology to the plight of the rural poor and the real issues of development, deserve commendation from all who put people before glory. ☐

Ziauddin Sardar is an Information Consultant to the Hajj Research Centre, King Abdul Aziz University, Jeddah, Saudi Arabia.

Chemistry at the University of Edinburgh

The Playfair Collection and the Teaching of Chemistry at the University of Edinburgh, 1713-1858. By R. G. W. Anderson. Pp.175. (The Royal Scottish Museum: Edinburgh, 1978.). Paperback £4.50.

SHORTLY after Lyon Playfair's appointment in 1858 to the Edinburgh Chair of Chemistry he presented to what is now the Royal Scottish Museum 75 diverse pieces of scientific apparatus from the University Chemical Laboratory which he believed to be of historical significance. Sixty-four of these items, thought to be associated with Black, Hope and Gregory, are extant and comprise the Playfair Collection. It is an important collection, as few pre-nineteenth century chemical artefacts of known provenance survive.

Dr Anderson devotes about half of his book to dicussing the provenance of the Playfair Collection as a whole and to describing fully each item, the first detailed discussion of its kind to be published. To provide a context for this catalogue the first half of the book describes the teaching of chemistry at Edinburgh from 1713 to 1858; during most of this period the University of Edinburgh was pre-eminent in Britain in the teaching of Chemistry, thus making Anderson's book of interest to both students of early scientific apparatus and historians of science.

In the catalogue section, the entry for each item consists of physical description, illustration, brief history of the development of the class of apparatus and, for some items, evidence for associating it with a particular Professor. The illustrations, both photographs and diagrams, are excellent and the brief histories are scholarly and well-referenced. The very difficult task of substantiating the association of a particular item with a particular Professor is capably done but, as is probably inevitable, the evidence is sometimes less than convincing.

The first half of the book, the author states, is not intended to be a history of the teaching of chemistry at Edinburgh or of those who taught it. This section deals primarily with their laboratories, their acquisition of apparatus and, to a certain extent, what and how they taught. In his principal aims the author succeeds admirably while supplying sufficient biographical material to make a continuous and readable account; it is particularly valuable to have hitherto unpublished information on the first holder of the Chair, Crawford, and extensive new information on his successor, Plummer, both of whom, other than in Underwood's *Boerhaave's Men*, have received little scholarly attention in contrast to their successors, Cullen, Black, Hope and Gregory. Anderson's account is well-referenced, mainly to primary sources, and is very lucid. The locations of the various laboratories are identified with very extensive evidence. Perhaps of wider general interest are the types of apparatus acquired, the costs thereof and the sources of supply; here again the author is to be congratulated on the range and depth of his research. Less well done is the account of the teaching which, though adequate as to the method of teaching, gives little information on the content of the courses. There are a few minor errors: for example, Crawford was allotted money not "to put up his stalls" (p4) but his "stells", Old Scots for "stills"; again, Lyon Playfair was a candidate for the Edinburgh chair in 1844 (p55) as the Town Council Minutes relating to that appointment show.

One matter of opinion on which I must express disagreement with the author is his view that *Opera Chemica* is a student notebook of Plummer's lectures. I believe it to be a set of instructions for the pharmaceutical preparations carried out in Plummer's laboratory; it is difficult to believe from Plummer's two published chemical papers that his chemical lectures were so narrow as to consist merely of pharmaceutical processes. These minor criticisms do not detract from my view that this is a splendid book which will interest not only the specialist but also the general reader and which at £4.50 is remarkable value.

W. P. Doyle

W. P. Doyle is Senior Lecturer in Chemistry at the University of Edinburgh, UK.

Origins uncertain

The Origin of the Solar System. Edited by S. F. Dermott. Pp. 668. (Wiley: Chichester, UK, and New York, 1978.) £28.50.

WE know and understand less about the Earth's interior than the Sun's. We know less about the origin of the planets than we do about the formation of stars and even (one may feel) of the Universe. This will be apparent to anyone who reads *The Origin of the Solar System,* the proceedings of a NATO Advanced Study Institute held at the University of Newcastle in 1976, and capably edited by S. F. Dermott.

The reason for this state of affairs is clear enough: we have only one example of a planetary system with closely measured physical properties, whereas we can observe a large number of stellar systems (and it is difficult to falsify statistically predictions about the Universe). Nevertheless, it leaves one uneasy to see a field of science so dominated by speculation, with so little hard observational foundation. For that reason one cannot escape a sense of unreality when reading this volume, which could not have been readily remedied in 1976. The discovery since then of strong candidates for pre-planetary discs around a handful of nearby stars by the Steward Observatory's infrared observing group gives some grounds for hoping that we may be able eventually to test hypotheses against planetary systems observed now to be in the process of forming. Certainly we are learning much about the Sun's birth processes — a subject not given much prominence in the present book — from recent observations of currently forming stars.

Within the book one does find various contributions which are well written and which may serve as excellent introductory reviews of specialised topics. The article by Kirsten on the use of radioactive decay for chronology using samples from the Earth, the moon and meteorites starts with an admirable discussion of principles and their application, and contains exact descriptions of a variety of experiments. One does not need to agree with the minutae in his final cosmochronology to be impressed with the precision, and the well understood limits to that precision, of estimates such as 4.5 to 4.6 x 10^9 yr for the epoch of Solar System formation. A complementary paper by Larimer on meteorites in an essentially similar style is also thorough and readable. In a very different type of article Stevenson sets out clearly how global physical observations of the outer planets — their mean densities, gravitational moments and their recently measured internally generated luminosities — set constraints on their physical and chemical structures. One is then left with the problem of how the resulting abundance ratios of hydrogen to helium and to heavier elements came to deviate from their cosmic and especially their solar values. Neglecting such cosmogonic considerations we have models for the interior of Jupiter more reliable and more able to describe observable phenomena (principally its huge magnetosphere) than comparable models for the Earth.

It is on the theoretical side where credibility wears thin. Reeves acknowledges this in his introduction, where he outlines four types of theories for planetary formation, two of which were postulated in their original forms in the eighteenth century, but all of which have their contemporary protagonists.

These are the single nebula hypotheses of Kant (1755) and Laplace (1796), the accretion theory of Berkeland (1912), the exploding binary component model originally proposed by Gunn (1932) and the two-star tidal filament picture first proposed by Buffon (1745). Each has been fully articulated by modern physicists (Hoyle, for example, has contributed to all of them), who have introduced much inventive detail. The earlier chapters of this book, written by authorities such as Cameron, McCrea, Woolfson and Prentice provide well-written accounts of particular modern variants of these theories. Each is able to account, more or less, for the principal features of the Solar System: the co-planarity of planetary orbits, the contrary imbalances of mass and angular momentum between Sun and planets, the Titius-Bode orbit relationship, and planetary chemical compositions. Each such chapter is well-reasoned and persuasive, with the exception of an irritatingly dogmatic essay by Alfvén, ostensibly critical of myth in science, but guilty of more unsupported assumption that any of the theories criticised.

Considered as a snapshot of the way the subject looked in 1976, and as a wide-ranging introduction to various aspects of the subject for students with a physics background, the book has much to recommend it. It is also a valuable case-study of the Popperian dictum that a necessary criterion for judging a scientific theory is its experimental or observational falsifiability. Although much of the theoretical work presented yields predictions which are falsifiable in principle, the authors must be aware that they are safe in practice, at any rate for the next few years. Only time and improved instrumentation will reveal the extent of their self-indulgence.

J. E. Beckman is in the Department of Physics at Queen Mary College, University of London, UK.

Cancer for the layman

The Wayward Cell. Cancer: Its Origins, Nature, and Treatment. Second edition. By V. Richards. Pp. 407. (University of California Press: Berkeley, Los Angeles and London, 1978). £8.75.

The Wayward Cell is a most interesting and unique treatise on various aspects of oncological diseases, their origins, nature and clinical care. It aims to provide facts and figures about cancer which are easily understandable to the intelligent layman as well as those involved with paramedical disciplines. However, I believe that this book will also interest and stimulate clinical oncologists, both those who are established and those in training.

The idea for the book almost certainly was born from the frustrations which clinicians not infrequently experience both with respect to their own failure to cure some tumours and with the need to provide clear concise explanations of the protean manifestations of cancer often sought by their patients.

This volume is divided into four main sections dealing with the biology, clinical aspects and treatment of cancer and some of the social problems it causes. The biology part is concerned with aspects of cell growth and differentiation together with modern views of the importance of molecular biology in enabling us to understand how cells work.

The clinical section is perhaps the best part of the book with a fascinating and informative account of the history of cancer. The importance of exposure to environmental carcinogens in causing the numerous cancers of this day and age is dealt with logically and clearly together with a simple account of the ways in which such carcinogens might influence cell growth and function. It is perhaps a pity that this section contains no simple pathological classification of the various types of tumours to illustrate their diversity of structure and histogenesis.

The section on treatment will be of particular value to the non-medical person giving, albeit with perhaps undue emphasis on breast cancer, the background to the various therapeutic modalities in current use.

The final part of the book is called "Cancer — 1977" and is an attempt to present the current state of our knowledge, its deficiencies and the prospects for the future. This section is disappointing, being too detailed and scientific for the lay reader. Elements would have been better integrated with the other sections.

Overall, this is a good book, well written and excellently illustrated with clinical case reports to reveal the patient problems which tumours create. Very few books of this nature are available with such a wealth of information. It should interest the range of readers for which it is intended.

A. Munro Neville

A Munro Neville is at the Ludwig Institute for Cancer Research, Royal Marsden Hospital, Sutton, UK.

Selected immunological methods

Immunological Methods. Edited by I. Lefkovits and B. Pemis. Pp.488. (Academic, New York and London, 1979.) $36; £23.40.

Immunological Methods is a misleading title for this volume of techniques. A non-immunologist hoping to find recipes for standard immunolgical methods, such as immunodiffusion in agar and immunoelectrophoresis, will be disappointed. A better title would be: *Experimental Techniques used by Scientists at the Basle Institute for Immunology.* This title, although slightly long for the spine of the book, would justify the inclusion of the chapters on nanomole peptide mapping (B.A. Moss, chapter 3), the production of sendai virus (R. Tees, chapter 30), the running of an isotope laboratory (H.M. Pohlit *et al.*, chapter 33) and the excellent introduction to polyacrylamide slab gel electrophoresis (B. Takacs, chapter 4), all of which can hardly be described as immunological methods.

The editors have pursued a policy of allowing individual contributors freedom of style and content. This approach has resulted in a variation in depth of treatment afforded different topics and an emphasis on murine cellular immunology. For example, serological typing of human histocompatibility antigens is briefly treated in 10 pages (J.W. Stocker and D. Bernoco, chapter 14). An assay for specific alloantigen binding T cells activated in the murine mixed lymphocyte reaction is treated in detail and clarity in 17 pages (Elliott *et al.*, chapter 21).

Another problem resulting from the lack of editorial direction is the repetition of several techniques in different chapters, the most exteme example of which is the description of suspension cloning techniques for lymphoid cells in three chapters (M. Shulman, chapter 20; N.N. Iscove and M.H. Schreier, chapter 29; G. Köhler, chapter 32).

Among the better chapters in the volume is a delightfully written account of antibody binding characteristics (S. Fazekas de of Groth, chapter 1). Another bonus is the presence of techniques for making monoclonal antibodies (G. Köhler, chapter 31), although this latter chapter would have been more valuable if it had been updated to include PEG fusion techniques and extended to include different screening techniques.

This book can be commended to specialist immunologists, particularly cellular immunologists, but does not serve as an introduction to immunological techniques for the non-specialist.

Peter Goodfellow

Peter Goodfellow is a staff scientist at the Imperial Cancer Research Fund's Laboratories, London, UK.

Arthropod phylogeny

Arthropod Phylogeny: With Special Reference to Insects. By H.B. Boudreaux. Pp. 320. (Wiley: New York and Chichester, UK, 1979.) £15.

THE past fifteen years have seen the publication of major works on arthropod phylogeny by Sharov, Hennig, Anderson and, notably, by Manton. Professor Boudreaux has now added to them a book distinguished by two guiding principles. Firstly, he believes that the Arthropoda form a single monophyletic taxon and therefore sets himself firmly against the recent tendency to regard them as three or more lineages, each independently evolved from primitive lobopod ancestors. Secondly, as an advocate of Hennig's methods of phylogenetic reconstruction, he proceeds by defining monophyletic sister-groups strictly through their common specialisations and abandoning, without much hesitation, the paraphyletic and polyphyletic taxa of the past.

After treating the Onychophora as a phylum separate from but related to the Arthropoda, Boudreaux devotes almost a third of his book to the affinities of the arthropod classes and the remaining two-thirds to the mutual relationships of the insect orders. The great diversity of the phylum, the volume of factual material, and the closely reasoned interpretations defy a brief summary, but the book has the great merit of presenting explicitly the foundations (mainly more or less familiar morphological data from living forms) on which the inevitably somewhat speculative inferences are based. Essentially the author recognises two main branches in arthropod evolution: a Cheliceromorph line, with the Pycnogonids, Xiphosurids, Eurypterids and Arachnids as its major subdivisions, and a more varied Gnathomorph line. The latter includes the Trilobites and the Mandibulata which (*pace* Manton) comprises the Crustacea, Myriapoda and the monophyletic Insecta.

To express his phylogenetic views in taxonomic terms, Boudreaux does not flinch from introducing, between the class Insecta and its constituent orders, no fewer than thirteen different taxonomic categories and the appropriate taxa, each duly named and defined. Within this rather cumbersome framework the evolutionary affinities of the orders are discussed in ways that are sometimes widely acceptable, sometimes more controversial. The Apterygota, Palaeoptera and Exopterygota are regarded as paraphyletic and discarded, although the Entognathan apterygotes are treated as a natural group. The order Mallophaga is restricted to the Amblycera, while a sister-group, the Anoplura, is redefined to accommodate the Ischnocera, Rhynchophthirina and Siphunculata. The Plecoptera, Dermaptera and Embioptera, all with notoriously obscure affinities, are hardly more convincingly placed than in alternative classifications, and similar doubts might also apply to the Thysanoptera, Strepsiptera and Siphonaptera. The Sialoidea, Raphidioidea and Plannipennian Neuroptera all receive separate ordinal status, but the Boreidae and Micropterigidae are denied it.

In many respects the resulting scheme for the insects is not unlike those proposed by Hennig or Kristensen. What must strike a more sceptical reader, however, is the tantalising scarcity of really crucial evidence and fully convincing arguments. Despite his confident style the author does, in fact, admit the tentative nature of many phylogenetic hypotheses. Their importance lies less, perhaps, in the permanent value of the conclusions reached than in their immediate heuristic value. In this sense the views and arguments of Boudreaux and those he represents should be welcomed: they will, along with the theories of their opponents, promote the study of Arthropod morphology, development and classification, and so, one hopes, make possible one day a more widely agreed phylogeny of the Arthropoda.

R.G. Davies

R.G. Davies is Reader in Entomology at Imperial College, University of London, UK.

Semiconductor devices

Semiconductors and Electronic Devices. By A. Barl-Lev. Pp. 381. (Prentice-Hall International: London and Englewood Cliffs, New Jersey, 1979.) Hardback £11.95, $22.95; paperback £8.95, $18.95.

THIS medium-sized book written by an electrical engineer for electrical engineers embarks on the ambitious task of introducing the reader to the physical principles of semiconductor materials and leading him on to a more detailed discussion of various aspects of junction and, to a lesser extent applications of semiconductor devices. In a sense, the title is slightly misleading, implying that devices other than semiconductor ones are being treated while, in fact, the discussion of vacuum devices is minimal.

The discussion of the physical and technological principles relating to semiconductor materials covers 114 pages in 8 chapters and is necessarily sketchy, as the author admits in the preface. However, I accept that the treatment is adequate for an electrical engineering student wishing to concentrate on the practical aspects of device performance.

The next three chapters are devoted to a discussion of various aspects of junction diodes, beginning with their static characteristics and including a description of varactor diodes. The optoelectronic devices mentioned include the PIN detectors, solar cells, light emitting diodes, optic couplers and even injection lasers — the treatment here is possibly at its most sketchy in view of the different physical background required for full understanding. A more thorough chapter on the dynamic response gives a discussion of diode switching.

The treatment of transistors begins interestingly and unconventionally with a discussion of field effect transistors both of the junction and of the insulated gate types, with a brief reference to integrated circuit design. This is followed by a chapter on the amplifying stage, transistor model and the equivalent circuit which is based on the characteristics of the MOS transistor but includes mention of vacuum device and bipolar transistor characteristics, neither of which had yet been introduced. The discussion of bipolar transistors starts with the large signal model and maximum ratings and only then proceeds to small-signal low- and high-frequency models. This is a sensible arrangement and these two chapters show a rather deeper level of treatment than most of the others. One chapter deals with an introduction to integrated circuits, both bipolar and MOS, to charge-coupled devices and integrated injection logic.

The chapter on microwave devices describes very briefly the relevant contructions of the bipolar and junction FETs, gives a very cursory discussion of varactor, step-recovery and IMPATT diodes, and finishes with the transferred electron devices. The main body of the text is completed with a chapter on silicon-controlled rectifiers and triacs. There are three appendices on two-port representations, thermionic emission and vacuum tubes — the last two somewhat incongruous in the present context.

On the whole, as an introductory text for electrical engineers this is a good and interesting book. It mentions, if only briefly, most of the recent developments in semiconductor devices that the student is likely to come across. There are useful Problems at the end of each chapter. My general criticism of this strongly device-oriented text is the relative paucity of actual device characteristics — the student would have benefitted a great deal from being able to see more performance data. Also, the list of 22 references for further reading is not adequate to guide a reader who wishes to follow up specialised topics.

ALBERT
EINSTEIN
1879–1979
Relativity, Quanta,
and Cosmology
in the Development of
the Scientific Thought
of Albert Einstein
Edited by
Francesco de Finis
October 1979 1024 pages 2 volumes

On March 14, 1979, the world celebrated the 100th birthday of Albert Einstein. To honor the memory of this seminal thinker, Johnson Reprint Corporation, in association with the Giunti Publishing Group of Florence, is proud to announce the publication in October 1979 of ALBERT EINSTEIN, a collection of outstanding essays on current developments in Einsteinian physics, all published for the first time in English.

Of the many great physicists of the twentieth century, none has produced a body of work as far-reaching and as crucial to our conception of the universe as Einstein. His papers on the theory of relativity, statistical mechanics, and the photoelectric effect were not only ingenious, but partook of that philosophical elegance which marked all of Einstein's work. In effect, he brought the science of physics into a new era.

Though many books on Einstein will be published this year, most of them will be addressed to laymen. In contrast, this collection, written entirely by prominent physicists, explores matters of concern to the professional scientist. Topics range from the development of mathematical physics and the search for gravitational waves to the philosophical component of the General Theory of Relativity and the cultural influences of Einstein's thought. Members of the international scientific community will find this two-volume set a comprehensive summation of recent research as well as an affirmation of Einstein's place in the history of ideas.

Contents:

Introduction
A. Carrelli

newly on the market

Pulsed source/detector systems. Oriel have further increased the range of accessories available for use with their pulsed light source and detector systems. The source has increased colour temperature for higher output, multikilowatt instantaneous intensity and a cool, compact package. When the source is used as part of a system incorporating the pulsed photometer, its range of applications is extended to include high sensitivity spectrofluorescence and reflection measurements. A new range of fibre optic accessories and a multipurpose sample compartment, together with the extensive catalogue of associated equipment previously available, now allow creation of total systems for a wide range of uses.

Digital function generator. ECO. The Model 567 digital function generator from ECO offers a unique combination of programming capabilities for electrochemical and corrosion research. A completely new kind of waveform programming based on pulse duration modulation provides waveforms completely free of spikes and steps with infinite voltage stability. A programming range over 7 orders of magnitude is available — from $1 \mu V s^{-1}$ to $10 V s^{-1}$, with resolution of 0.01%. The new circuit has extremely slow ramp rates, and digital controls allowing 20,000 individual settings of both ramp rate and amplitude. In addition, the digital circuitry affords optional BCD inputs for control of ramp rate, delay, level and trigger for remote programming by computer. Waveforms available include ramp, triangle, trapezoid and staircase.

Standardised radioactive solutions. Radiochemical Centre. Standardised solutions of the following radionuclides are now available from the Radiochemical Centre: calcium-45, iodine-125, phosphorus-32, mixed radionuclide standard, barium-140, cerium-141, strontium-89, sulphur-35, phosphorus-32, selenium-75 and yttrium-90. Pre-dispensed combustible standards of carbon-14 and tritium for checking sample oxidisers are available in packs of 50 standards. The amount of carbon-14 or tritium in any standard in a pack is guaranteed to be within ± 1% of the average amount in each standard in the pack. Each standard contains approximately 100 mg of combustible material but the total combustible mass should be adjusted by adding compressed filter paper or other material to simulate the mass of the samples normally burnt. Carbon-14 is also supplied as sodium carbonate solution and as a solution of glucose in water.

Animal drinking monitor with printer. Columbus Instruments. For measuring the trend of drinking activity of laboratory animals, the miniature drinking monitor from Columbus Instruments is equipped with periodic timer and printer. The total size including printer is 4×11×3 in. Rechargeable battery operation allows its use in any remote area. It can also be line operated. The drinking monitor (Drink-Print-1) totals the number of licks of the animal on the water dispenser and prints the totals in selected time intervals. Internal timer is crystal controlled and has four selectable intervals of 1, 2, 5 and 10 min. Printing is on ordinary office machine paper tape.

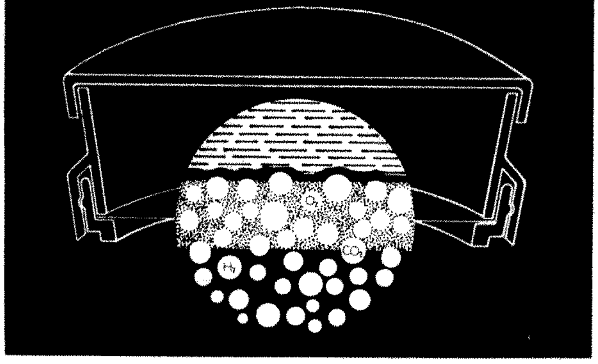
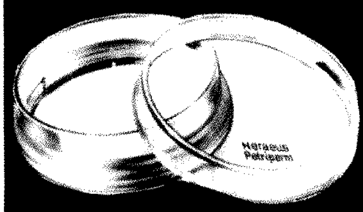
A new approach in tissue culture





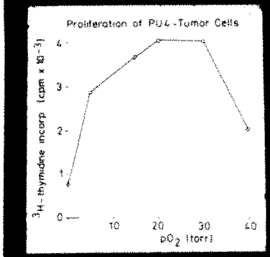
PETRIPERM

a novel culture dish with gas permeable membrane as cellular support.

Additional advantages of the PETRIPERM membrane are:

- UV permeable 200 nm
- Suitable for high power light and fluorescence microscopy
- The membrane can be cut for cell cloning, electron microscopy, staining and documentation
- Chemically resistant to acids, bases and organic solvents

PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.



In the intact animal, the pH, and the partial pressure of both oxygen and CO_2 of the cell environment are under total biochemical and physiological control. This state is not even approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. PETRIPERM is the prerequisite for the precise control of pO_2, pCO_2 and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable 25 μm thick membrane.

Practical Electron Microscopy in Materials Science

Transmission electron microscopy has progressed from being a specialist technique to become the most important of many techniques available in the study of a wide range of problems in metallurgy and materials science.
It is often necessary therefore for non-specialist research workers and students to have a sound appreciation of how to interpret quantitatively the various details of both images and diffraction patterns without having to study complex theoretical background material.
This large-format series of five monographs presents in a concise and easily assimilable form, the conclusions of electron diffraction theory in such a manner as to simplify the interpretation of experimental results. Only a limited amount of theory is included, the emphasis being on the use of the conclusions both to operate the microscope efficiently and to interpret the results accurately.

Specific endopeptidase for sequence analysis. Pierce. Submaxillaris protease, an arginyl-specific endopeptidase, is now available from Pierce. Isolated from the submaxillary glands of mice, it is reported to demonstrate greater specificity than Clostripain towards the arginyl peptide bond. Use of submaxillaris protease promises to be a most effective approach to obtaining arginyl terminating peptides for sequence analysis. No modification of lysine side chains is necessary to direct cleavage to arginyl loci in peptide chains. The protease is supplied lyophilised and salt-free in 100-unit packages.
Circle No. 95 on Reader Enquiry Card.

Freeze-drying station. FTS Systems. Dynamic testing of heat-sensitive biologicals is performed in twin 14-freeze-dryers which are coupled to a programmable, recording console. Either unit may operate independently or simultaneously for comparison-testing the effects of vacuum and heat input to products while all variables are recorded on the control console. Special features include; low mass, fully flooded, stainless steel product-shelves with a product-freezing and heating facility. Product trays are locked down to make firm contact with the temperature-controlled shelves; materials with high acid resistance are used in the ice condensing system. Gas sterilisation, full micrometer control over vacuum and sterile air inlets, and special accessories to match individual product-drying requirements.

Vacuum/compressor pump. The Edwards D.1 diaphragm pump achieves vacuum better than 200 mbar and delivery pressure of 4.2 kgf per sq cm, and is completely oil-free in operation. The pump weighs only 7.7 kg and its noise level is only 50 dB(A). Complete with carrying handle, the D.1 is very reliable and simple to maintain. The main shaft is of constant diameter, eliminating potential failure points, and simple disposable filters can be rapidly changed. The pump design makes subsequent incorrect assembly impossible. Inlet and exhaust ports are both in the head, which can be rotated through 180° to reverse their positions.
Circle No. 97 on Reader Enquiry Card.

Micromanipulator. Singer. The purpose of the Singer Microforge is to make easily from glass, micropipettes, needles both straight and curved, loops etc. The glass and heating element are viewed through a binocular eyepiece microscope with fine focusing. The glass and platinum heating element are held in fully adjustable and rotatable holders and the special feature of the instrument is that these holders are manipulated by two joysticks that move the work in the focal plane. This design advance makes possible, with little practice, the performance of intricate and complicated movements. The microscope and joysticks and other controls are conveniently mounted on a single rigid chassis within the instrument case. The heating element is thyristor controlled, and the element temperature is smoothly and finely adjusted by a large, conveniently placed knob.
Circle No. 88 on Reader Enquiry Card.

Nick translation system (^{32}P). New England Nuclear announce the availability of their new nick translation system dCTP, $[\alpha\text{-}^{32}P]$—for performing nick translation of DNA. The resulting labelled DNA product is suitable for use in kinetic studies (as a substrate for restriction enzyme digestion) or probe hybridisation methodology. The eight-vial system includes all necessary components for approximately 20 reactions.
Circle No. 98 on Reader Enquiry Card.

Portable data logging systems. Microdata. The M1600L from Microdata is a multi-channel data logger recording on a computer-compatible magnetic tape cartridge. It is capable of interfacing with any types of analogue or digital transducer by the use of a separate plug-in signal conditioning module for each channel. The basic instrument can accommodate up to 20 modules in its own case (making a 20-channel capacity), with provision for expansion to 100 channels by the use of add-on units. An important feature in the load monitoring application is the M1600L's self-contained portability. It requires no external power supply, and is capable of operating for long periods without attention from its internal rechargeable battery.

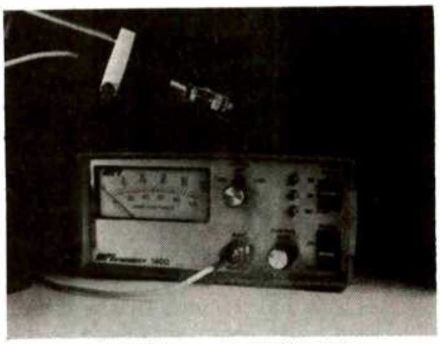
ANALTECH

Circle No. 20 on Reader Enquiry Card.



The W-P Instruments nanolitre pump

Programmable computerised image analysers. The new Quantimet System 23 from Cambridge Instrument Company, is a fully programmable, computerised image analyser that does not need a programmer. The new System 23 enables the operator to write comprehensive application-specific programs for his specimens without knowledge of programming languages or computer skills. A unique interactive image analysis keyboard, together with a powerful and versatile software operating system makes it all possible. Once a program is written, it can be stored on a high-speed magnetic disk enabling immediate use whenever required. The System 23 provides an additional capability for those operators who can program in FORTRAN and BASIC.

Circle No.100 on Reader Enquiry Card.

Nanolitre pump. W-P Instruments. A small, light-weight instrument from W-P Instruments for micro-perfusion, chemical titration, and bioassay use can be brought directly to the site at which fluids will be delivered or removed at rates from below 5 nl $\min^{-1}$ to 100 nl $\min^{-1}$. Fluid delivery is effected by a glass micropipette drawn to a tip diameter in the 3–10-μm range. The pump body contains a precision d.c. miniature motor. Motor speed is kept constant by electronic feedback control. Electrolytes, drugs, dyes and other fluids may be displaced into or out of the pump in extremely small volumes and with variable rates. It is designed to be mounted in any standard micromanipulator.

Circle No.101 on Reader Enquiry Card.

Micro-computer. IN/US Service Corporation. A new four-page brochure published by IN/US Service Corporation describes the Model 5000 Micro-Computer, which can turn a terminal into a computer. The Model 5000 may be used for many applications in bio-medical laboratories and the brochure gives particular emphasis on liquid scintillation and gamma counting. Simplicity of programming is a feature of the Model 5000. Although the Model 5000 has been designed to be user-programmed, it is delivered with turn-key programs for a variety of counting and statistical applications.

Circle No.102 on Reader Enquiry Card.

HPLC peak collector. Gilson. A new peak selective fractionator collecting only peaks has been announced by Gilson Medical Electronics. The peak collector connects to UV, visible or fluorescence detectors to perform high flow preparative collection or repeat sample injection for HPLC. Peaks are identified by the threshold level and by increasing or decreasing concentration. Peak identification circuitry controls the mobile indexing head, collecting one peak per tube and up to 15 peaks per sample injection.

Circle No.103 on Reader Enquiry Card.

Monitoring thermometer. The TM-10 thermometer from Bailey Instruments was designed for monitoring during hyperthermia therapy and other situations where accuracy of reading is vital. Temperature range is 0–140°C with 0.1°C resolution. Display is digital with ½ in liquid crystal numerals. A built-in reference oven, entirely independent of the thermometer circuit, has ±0.02°C stability and allows instant calibration check. There are five pushbutton-selected probe inputs for type T thermocouples and two implantable microprobes (Bailey type IT-18) are included. The panel-mounted digital clock shows either time-of-day or elapsed time for convenience in maintaining treatment records.

Computer Science and Technology

New titles

Planning for Data Communications

J. E. Bingham and G. W. P. Davies

Presents practical guidelines for those concerned with information systems development who are not themselves data communications specialists. The authors give a step-by-step description of the progressive implementation of an overall strategy, followed by an analysis of the main factors upon which its success depends.

1977, £10.00/£4.95

Fundamentals of Data Base Systems

S. M. Deen

Explains the basic principles of a Data Base System, and shows how these are tackled in the major models and packages, discussing implementation and user problems and assessing likely future developments.

1977, £8.95/£4.85

Programming and Problem Solving in Algol 68

Andrew Colin

An introduction to the art of programming and a grounding in the specific language of Algol 68. The author provides much background information about the environment in which computers operate, introduces algorithms such as sorting and searching, and gives many examples throughout.

1977, £4.50.

Analysis and Design of Sequential Digital Systems

L. F. Lind and J. C. C. Nelson

Begins by introducing logic design and several concepts to be used later in the work, and goes on to examine combinational-logic design (developing and using the Karnaugh map) and sequential design, both synchronous and asynchronous. Topics covered include stable and unstable states, excitation and flow maps, input and output maps, static, dynamic and essential hazards, and merging and state assignment.

1977, £8.95/£4.50

Established titles

Microprogramming

Guy Boulaye

Edited by P. A. Beaven

A concise introduction to microprogramming for students of computer sciences, computer technology and (digital) electronic engineering.

1975, £3.95 paperback.

Experiments with Operational Amplifiers: Learning by Doing

G. B. Clayton

Covers a range of practical operational amplifier applications. The author contends that the quickest way for the non-specialist to learn about amplifiers is to use them in working circuits, and aims to give a practical understanding of the principles behind each application.

1975, £2.95 paperback.

Automata

D. R. Hopkin and Barbara Moss

Macmillan Computer Science series

A self-contained account of the theory of finite and infinite automata, with special reference to those machines which model aspects of computation. The text assumes no previous knowledge of logic or formal arithmetic, and develops the theory through a wide variety of worked examples.

1976, £8.95/£3.95

Fundamentals of Operating Systems

A. M. Lister

Macmillan Computer Science series

An introduction to the fundamentals of computer operating systems, emphasising the structural aspects of system design, suitable for those who already have some grounding in computer science.

1975, £7.95/£2.95

Forthcoming titles

A Handbook of Systems Analysis

Second edition

John Bingham and Garth Davies

A practical guide to the design and use of systems for data collection and processing in the business situation, updated to take account of recent developments and current trends.

1978, about £5.95

The ICL 2900 Series

John Buckle

Macmillan Computer Science series

An explanatory guide for readers who are familiar with general computer concepts and wish to gain a broad understanding of the 2900 series.

1978, about £3.95 paperback

Fortran, PL/1 and the Algols

Brian Meek

1978, about £6.00

If you would like to see an inspection copy of any of these books, please write to Miss Kim Mitchell, Dept P3(N), The Macmillan Press Ltd, Little Essex Street, London WC2R 3LF.

APPOINTMENTS VACANT

UNIVERSITY OF BIRMINGHAM

THE DENTAL SCHOOL

LECTURESHIP (non-medical)

in the DEPARTMENT of ORAL PATHOLOGY

Applications are invited for the post of

LECTURER in BIOCHEMISTRY

in the above department. The department is responsible for teaching Oral Biology and Oral Pathology to dental students. The person appointed will be expected to have a particular interest in the biochemistry of the mouth and jaws, and will teach these aspects of the course. In addition, it is anticipated that the successful applicant will take part in the teaching programme of the Department of Biochemistry. Opportunities for research are excellent and it is hoped that the occupant will participate in the varied collaborative research programmes currently going on in the department, in addition to his own research.

Salary on the scale £4,333 to £8,992 (from 1.10.1979).

Further particulars available from the Assistant Registrar, The Dental School, St. Chad's Queensway, Birmingham, B4 6NN, with whom applications, including a full *curriculum vitae* and the names of three referees, should be lodged by *28th September 1979.* 3087(A)

THE UNIVERSITY OF LEEDS

DEPARTMENT OF PLANT SCIENCES

Applications are invited for two posts of Postdoctoral

RESEARCH FELLOW

in plant physiology and biochemistry, available in the above Department. Candidates should have a good Honours Degree in Botany, Biology or Biochemistry and a PhD in Plant Physiology or Biochemistry. The posts are available in a group working on the regulation of C_3, intermediate and C_4 metabolism in the photosynthesis of crop plants with particular reference to temperature. The work is concerned with analysis of metabolite fluxes and the enzymology of rate-limiting steps in photosynthetic assimilation of CO_2. The research group is directed by Professor H W Woolhouse and is financed by the ARC. The posts are tenable for up to 5 years from October 1979.

Salary on the IA scale for Research and Analogous Staff (£4,333 to £7,521) (under review).

Further information may be obtained from Professor H W Woolhouse, Department of Plant Sciences (Baines Wing), University of Leeds, Leeds LS2 9JT.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 53/12. Closing date for applications 30 September 1979. 3090(A)

LEICESTERSHIRE AREA PATHOLOGY SERVICE
DEPARTMENT OF CHEMICAL PATHOLOGY

Applications are invited for the post of

BASIC GRADE BIOCHEMIST

from suitably qualified graduates. The Area laboratory at The Leicester Royal Infirmary offers wide experience of automated and non-automated techniques. New laboratory accommodation is due to be opened shortly.

Further details may be obtained from:
Dr T.J. Davies, Consultant Chemical Pathologist, telephone Leicester (0533) 541414 ext. 5574 or 331 who can arrange visits to the laboratory.

Applications, with curriculum vitae and names of two referees should be sent to the Hospital Administrator, The Leicester Royal Infirmary, Infirmary Square, Leicester.

Closing date for receipt of applications: 17th September, 1979.

Leicestershire Health Service 3140(A)

LEICESTERSHIRE AREA HEALTH AUTHORITY (TEACHING)

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

South Kensington,
London S.W.7.

POST-DOCTORAL RESEARCH AT Imperial College into

ENHANCED OIL RECOVERY RESEARCH

The Department of Mineral Resources Engineering invites applications for two post-doctoral research posts (SRC sponsored) tenable for up to three years for the study of:

1. The behaviour of emulsions in reservoir rocks.
2. Capillary effects in the enhanced recovery of oil from reservoir rocks.

The work is of fundamental importance to oil recovery processes and requires an appreciation of fluid-surface interfacial phenomena and porous media.

Starting salary in the 1A range £4,762 to £7,647 (under review) with U.S.S. Initial placing dependent on age, qualifications and experience.

Enquiries and applications (giving curriculum vitae and the names of two referees) to the professor of Petroleum Engineering, Department of Mineral Resources Engineering, Imperial College of Science and Technology, London SW7 2BP, or for further details telephone Dr R.A. Dawe on 01-589 5111 ext 1555 or ext 1531.

A number of studentships for study to PhD are also available. 3095(A)

STANFORD UNIVERSITY

GEOCHEMIST —PETROLOGIST

The Department of Geology in the School of Earth Sciences invites applications for a faculty position beginning September, 1980. Areas of interest include (but are not limited to) geochemical processes in the crust and mantle of the earth including isotope geochemistry, thermodynamics, kinetics, element distribution and phase equilibria studies. Teaching responsibilities might include graduate and undergraduate courses in geochemistry and igneous petrology. Level of appointment is open, but we are particularly interested in a creative young person, with a well-established record in research.

Applications should include (1) a resume of education, professional experience, and published research; (2) a brief statement of plans for future research, and (3) the names of 4 referees. Send to: Prof. J.G. Liou, Department of Geology, Stanford University, Stanford, CA 94305, by December 1st, 1979. Stanford University is an equal-opportunity/affirmative-action employer. W329(A)

SIMON FRASER UNIVERISITY

Burnaby, British Columbia, Canada.

DEPARTMENT OF BIOLOGICAL SCIENCES

DIRECTOR OF MASTER OF PEST MANAGEMENT PROGRAM

Applications are invited for the vacant position of Director of the Master of Pest Management (MPM) program and related activities at Simon Fraser University.

The appointment will be at the rank of Associate Professor or Professor, with level and salary commensurate with training and experience. The successful candidate should have an established professional and academic reputation in pest management and a current research program in at least one aspect of pestology. Responsibilities will include the development and organisation of the MPM program as well as research and teaching in the individual's area of expertise. The position is available as of 1 September, 1979, subject to budgetary approval. The current salary range for the Associate Professor and Professor rank is, respectively, $25,636 to $41,018 and $31,552 to $55,216 per annum.

Applications, including an up-to-date curriculum vitae, copies of representative recent publications and the names of at least three referees, should be sent to: Dr M Mackauer, Chairman, Department of Biological Sciences, Simon Fraser University, Burnaby, BC, Canada, V5A 1S6 from whom further information may be obtained. Applications will be received until 31 October, 1979 or until the position is filled. W341(A)

UNIVERSITY OF NEWCASTLE UPON TYNE

CHAIR OF THEORETICAL PHYSICS

Applications are invited for the Chair of Theoretical Physics in the School of Physics from candidates whose teaching and research interests lie broadly within that field. It will be an advantage if an applicant is a theorist with primary interests related to areas of activity in one of the School of Physics' three departments. The appointment, which is available from the 1st October 1980, carries with it the Headship of the Department of Theoretical Physics for an initial period of five years. Salary will be in the professional range.

Further particulars may be obtained from the Deputy Registrar, University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne, NE1 7RU with whom applications (15 copies) giving the names of three referees, should be lodged not later than 31st October 1979. (Applicants from outside the British Isles may submit one copy only.) 3082(A)

SCHOOL OF PHYSICAL SCIENCES POSTDOCTORAL RESEARCH ASSISTANTS IN CHEMISTRY

Applications are invited for two S.R.C. sponsored research posts, each tenable for two years from 1st October, 1979 (or as soon as possible thereafter).

The first appointment (quote Ref: 79/63) will involve research into the photochemistry of intramolecular charge-transfer systems, with Dr D.J. Cowley. Previous experience in luminescence/optical spectroscopy would be an advantage.

The second appointment (quote Ref: 79/64), which will be under the supervision of Dr A.C. Knipe, will involve investigation of 'Organic Reaction Mechanisms', with particular emphasis on novel elimination reactions of sulphonamide derivatives and the reactivity of small-ring systems.

The commencing salary for each post is £4,910 per annum (with FSSU/USS).

Further particulars may be obtained from the Registrar, The New University of Ulster, Coleraine, Northern Ireland, BT52 1SA (quoting appropriate reference number) to whom applications including the names and addresses of three referees should be sent as soon as possible.

3085(A)

POSTDOCTORAL FELLOW or RESEARCH ASSOCIATE to participate in studies of molecular events in RBC differentiation and development, including studies of nucleic acid synthesis, production of globin and non-globin proteins, and iron metabolism. Applicant should have experience with biochemical methods for analysis of nucleic acids *or* protein synthesis. Salary range $11,500 to $14,000 depending upon experience. Send curriculum vitae, including 3 references to: Dr Joseph A. Grasso, Department of Anatomy, University of Connecticut Health Center, Farmington, Connecticut 06032

W348(A)

THE UNIVERSITY OF LEEDS

DEPARTMENT OF PLANT SCIENCES

Applications are invited for a post of

RESEARCH ASSISTANT

in plant physiology biochemistry, available in the above Department. Candidates should have a good Honours Degree in Botany, Biology or Biochemistry; the opportunity will exist for the holder of the post to register for a higher degree. The post is available in a group working on the regulation of photosynthesis in crop plants with particular reference to effects of temperature. The work is concerned with analysis of metabolite fluxes and the enzymology of rate limiting steps in the photosynthetic assimilation of CO_2. The research group is directed by Professor H W Woolhouse and financed by the ARC. The post is tenable for up to 5 years from October 1979.

Salary on the IB scale for Research and Analogous Staff (£3,775 to £5,488) (under review).

Further information may be obtained from Professor H W Woolhouse, Department of Plant Sciences (Baines Wing), University of Leeds, Leeds LS2 9JT.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 53/13. Closing date for applications 20 September 1979.

3091(A)

CITY OF BIRMINGHAM POLYTECHNIC

Faculty of Engineering and Science

DEPARTMENT OF SCIENCE

LECTURER II/SENIOR LECTURER in BIOMEDICAL SCIENCES (PHYSIOLOGY)

required to contribute to the teaching of courses in Medical Laboratory sciences, Speech Therapy and Biological Science. Candidates should have suitable academic qualifications and have a keen interest in contributing to the development of research activity in the appropriate field of Human Physiology but an ability to contribute to the teaching of Cell Biology and/or Genetics would be an advantage.

Salary Scales:

SENIOR LECTURER: £6,597 to £7,701 (bar) £8,253

LECTURER II: £4,470 to £7,149.

Further details and application forms (to be returned by 21st September 1979) from: The Personnel Officer, City of Birmingham Polytechnic, Perry Barr, Birmingham B42 2SU. (021-356 6911, Ext. 217).

3093(A)

ASSISTANT OR ASSOCIATE Professor of Entomology to conduct systematics research and teach principles of systematics and insect classification. PhD required. Submit curriculum vitae, transcripts, description of research experience and plans, reprints of publications, dissertation summary, summary of teaching capabilities, names of 3 referees to A.A. Grigarick, Chairperson, Search Committee, Department of Entomology, University of California, Davis, CA 95616 by October 1, 1979. An Equal Opportunity /Affirmative Action Employer.

W335(A)

UNIVERSITY COLLEGE OF WALES

Welsh Plant Breeding Station

Applications are invited for the post of

HEAD OF SEED PRODUCTION DEPARTMENT

The Department has responsibility for production and processing of seed stocks for Station and National List trials and for Pre-basic seed stocks of Station-bred varieties. Its research programme is concerned with the development of effective seed production techniques, with emphasis on seed yield and quality. An important aspect of the post is liaison with public and private organisations concerned with seed production, testing and certification.

The candidate should have a good Honours degree in agricultural or biological science, with considerable experience in plant breeding and/or seed production.

The post is in the PSO range at a salary of £7,534 to £9,646 per annum (from 1 January 1980, £8,513 to £11,343). *Non-contributory* superannuation scheme but male employees contribute 1½% towards family benefits.

Further particulars and application forms are obtainable from The Secretary, Welsh Plant Breeding Station, Plas Gogerddan, Nr Aberystwyth, Dyfed, SY23 3EB. Closing date Monday, 1 October 1979. Please quote reference 45.

3136(A)

Physicist/ Physical Chemist

BP has a vacancy for a physicist or physical chemist in its Exploration and Production Division at the BP Research Centre, Sunbury-on-Thames.

The work is within a small but expanding group engaged in research into the physical basis of oil recovery. Applicants should have experience in the measurement of the thermodynamic or transport properties of fluids, preferably to Ph.D. level, together with an interest in the Earth Sciences. You will be expected to make a contribution to the philosophy and direction of the project work and have the ability to translate oil field problems into physical and mathematical models.

Salary will be dependent on qualifications and experience and assistance will be given with relocation expenses where appropriate. You will have the benefit of a non-contributory pension scheme, subsidised lunches and an excellent sports and social club.

If you would like to be considered for this post, please write giving details of your career, qualifications and experience to: Mrs. L. Fuller, Personnel, BP Research Centre, Chertsey Road, Sunbury-on-Thames, Middlesex TW16 7LN. The closing date for application is Monday 17th September 1979.

BP Research Centre
Sunbury on Thames

(3108)A

UNIVERSITY OF NEWCASTLE UPON TYNE

Department of Geology

DEMONSTRATORSHIP IN PETROLOGY

Applications are invited for a full-time demonstratorship for three years from 1st October 1979 or as soon after that as can be arranged. The successful candidate will teach the petrology, geochemistry and mineralogy of igneous and metamorphic rocks, and hydrothermal ore deposits, as well as some basic geology. Postgraduate experience in this general area is a necessary pre-requisite. Opportunities will be available for developing new courses. Research is strongly encouraged.

Salary will be at an appropriate point on the Grade 1B (bar) scale £3,775 to £5,488 per annum according to age, qualifications and experience. Membership of the appropriate University superannuation scheme will be required.

Further information can be obtained from Professor J.R. Cann, Department of Geology, The University, Newcastle upon Tyne NE1 7RU, with whom applications (2 copies), giving the names and addresses of three referees should be lodged as soon as possible and in any case not later than 14th September, 1979.

3123(A)

MEDICAL RESEARCH COUNCIL

DEVELOPMENTAL NEUROBIOLOGY UNIT

INSTITUTE OF NEUROLOGY

Applications are invited from scientists with a few years of postdoctorate experience for a 5 year limited term position. The research primarily concerns the characterisation of neurotransmitter systems of the cerebellum, including studies on isolated cell types and cultured cells from the cerebellum, and also involves collaborative work with morphologists in the Unit. Previous experience in biochemical neuropharmacology, membrane biochemistry and/or cell biology would be an advantage. Salary on MRC Non-clinical Scientific Staff scales depending on age and experience (Grade II, £4,232 to £6,627 or Grade I £6,757 to 8,452 plus £502 London Allowance).

Applications, together with full curriculum vitae and the names of two professional referees should be sent to Dr R. Balazs, MRC Developmental Neurobiology Unit, Institute of Neurology, 33 John's Mews, London WC1 2NS.

3129(A)

Public Health Laboratory Service

PHLS Centre for Applied Microbiology & Research

Diagnostic Reagents Laboratory

Basic Grade Microbiologist

A research biochemist with experience in enzymology and peptide chemistry is required. The position will involve research on the development and characterisation of new proteins/enzymes for use in diagnostic assays; the development of new assay systems for the detection of a wide range of compounds, including human metabolites and the detection and analysis of peptides, in particular those in serum.

Salary will be in the range £3,486 to £5,592 increasing to £3,807 to £6,075 on 1.1.80. NHS terms and conditions of service.

The post may be discussed informally by contacting Dr R. Sherwood or Dr A. Atkinson, Diagnostic Reagents Laboratory. Tel. Idmiston (0980) 610391, exts 435/393.

Applications including curriculum vitae and names and addresses of two academic referees to Mrs M. Bushby, Personnel Officer, CAMR, Porton Down, Salisbury, Wilts SP4 0JG. Tel: 0980-610391, ext 298. Closing date 21 September, 1979.

Special Pathogens Reference Laboratory

Principal Grade Microbiologist

(£7,995 to £10,458 increasing to £9,129 to £12,306 on 1.1.80)

A Principal Grade Microbiologist is required by the Special Pathogens Reference Laboratory to institute and develop a programme of biochemical and immunochemical investigations of viral pathogens of interest to the laboratory. At present these include Lassa, Marburg and Ebola viruses and certain arboviruses. The appointee will be responsible to the Director of the laboratory, and will be expected to share in routine laboratory investigations. He/she will lead a small research team.

Qualifications: A PhD obtained in the field of viral biochemistry together with at least 3 years of post-doctoral research experience preferably with work on human pathogens. It is envisaged that the appointee will already have experience of the procedures required for the growth and purification of viruses together with a knowledge of methods for the separation of viral proteins. Previous experience in the serological and immunochemical analysis of viral protein components would be of advantage.

The Laboratory Director, Dr D. Simpson, would be pleased to discuss the post informally with interested candidates, tel. 0980-610391.

Applications including Curriculum Vitae and names and addresses of two academic referees to be submitted to Mr R.S. Sawyer, PHLS HQ, 61 Colindale Avenue, London NW9 5EQ. Tel 01-200 1295. Closing date 5 October 1979.

LABORATORY MANAGER

Grade 10 (£7,464 – £8,040 + £312 Supplement)

(Salaries under review)

The Welsh Water Authority has five Area Laboratories which provide a complete analytical service (chemical, biological and microbiological) across Wales.

A vacancy exists for the position of Laboratory Manager at the Nash Laboratory situated outside Newport, Gwent. The Laboratory Manager is an outposted member of the Directorate of Scientific Services and will report to the Laboratory Controller. Applicants must be enthusiastic and well qualified Scientists who have had experience in managing a multi-disciplinary laboratory or group of Scientists. Experience in one or more aspects of the water cycle would be a distinct advantage.

The Laboratory has a staff of about 30 and consists of a number of groups covering the various disciplines. A high degree of automated analysis is in use.

The terms and conditions of employment are as laid down by the National Joint Council for Water Service Staffs. Relocation expenses are payable in appropriate cases and a Regular User Car Allowance is attached to this post.

Application forms may be obtained from:

Assistant Personnel Officer (Ref 2L002)
Welsh Water Authority Cambrian Way
Brecon Powys, LD3 7HP
Tel: Brecon (0874) 3181 Extension 373
Closing Date for applications: 24th September 1979

WELSH WATER AUTHORITY
AWDURDOD DWR CYMRU

3141(A)

TECHNICIAN IN PHYSIOLOGICAL PHYCHOLOGY required in the Department of Psychology to assist in teaching and research laboratories. Duties will involve work with animals. Previous experience with histological, biochemical, physiological or pharmacological procedures will be advantageous. Applicants should have HNC Biology or equivalent. Salary Scale £3,222 to £3,708 p.a. Application form from Assistant Secretary, Personnel Office, University of Birmingham, PO Box 363, Birmingham B15 2TT. Ref. 121/c/372. 3112(A)

THE UNIVERSITY OF SHEFFIELD

ACADEMIC DIVISION OF MEDICINE

LECTURESHIP IN PHARMACOLOGY AND THERAPEUTICS

Applications are invited from men and women for the above post in the University Department of Pharmacology and Therapeutics. Duties include teaching experimental pharmacology to students of medicine, dentistry and pure science. In addition to teaching and administrative duties, the undertaking of original research in some aspect of experimental pharmacology is required. Initial salary in range £4,333 to £5,199 a year on scale rising to £8,992 a year. Those interested should in the first place contact Professor H.F. Woods, Department of Therapeutics, the Hallamshire Hospital, Sheffield S10 2JF. Tel. 0742 26484 ext. 2475. Further particulars from the Registrar and Secretary, the University, Sheffield S10 2TN to whom applications (8 copies) should be sent by 1 October 1979.

Quote ref: R 355/G. 3092(A)

TEMPLE UNIVERSITY, Department Biology, Postdoctoral Position. A tw year postdoctoral position in mammalia developmental genetics and reproducti biology is available immediately. Initi salary is $10,500 p.a. plus fringe benefit Applicants should send, as soon possible, a curriculum vitae and names of referees to Dr Nina Hillman, Temp University, Biology Departmen Philadelphia, Pennsylvania 19122.

W340(A)

UNIVERSITY COLLEGE CARDIFF

Applications are invited for an

SRC POST DOCTORAL FELLOWSHIP

available for suitably qualified candidat to work with Dr J.W.T. Wimpenny in t Department of Microbiology, c quantitative aspects of the growth microorganisms in solute gradients. T successful applicant will join a grou investigating the biology of three differe diffusion systems, and will be responsib for generating mathematical mode capable of defining and predicting t growth and interactions of organisms solute gradients. Applicants having suitable mathematical background a anxious to gain some experience in biological discipline are sought.

The appointment is tenable for 2 years a starting salary of £4,333 (under review

Applications (2 copies) includi curriculum vitae and the names a addresses of two referees should forwarded to the Vice-Princip (Administration) and Registrar, Universi College, PO Box 78, Cardiff CF1 1X. Closing date 1st October 1979. Referen 1891. 3111(A)

Southampton THE UNIVERSITY

DEPARTMENT OF BIOLOGY

A research Assistant is required to work with Dr. P. Thorogood on an MRC-funded project concerned with the role of cell and tissue interactions in the differentiation of neural crest cells. Applicants should have a good honours degree in one of the biological sciences, a strong interest in developmental biology and one or two years experience in a research laboratory. Expertise in cell and tissue culture techniques would be an advantage. The post is tenable for three years commencing 1st October, 1979 or as soon as possible after that date, and the initial salary will be up to £4,055 per annum. Registration for a higher degree will be considered. Applications, together with a curriculum vitae and the names of two referees should be sent as soon as possible to Dr. P. Thorogood, Department of Biology, Medical and Biological Sciences Building, Bassett Crescent East, Southampton SO9 3TU. Please quote reference number 1602/R/N.

3121(A)

WELSH NATIONAL SCHOOL OF MEDICINE

(University of Wales)

DEPARTMENT OF HAEMATOLOGY

TECHNICIAN (ELECTRON MICROSCOPY)

A technician experienced in electron microscopy is required to carry out routine processing of blood, bone marrow cells and other tissues. The person appointed will have the opportunity to take part in the department's research programme in erythropoiesis and iron metabolism and to develop an individual interest. The School's electron microscope unit is now adding a Philips 400 STEM to its equipment and this will be operational early in 1980.

Salary for State Registered technicians will be on the scale for medical laboratory technical staff (£3,768 to £5,391 per annum) or that for Senior Medical Laboratory technical staff (£5,016 to £6,585 per annum) as appropriate. The department may be visited by arrangement with Professor A. Jacobs (Cardiff 755944 Ext. 2375).

Application forms available (quoting ref. No.H24/1) from the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff CF4 4XN to whom they should be returned 2 weeks from the date of appearance of this advertisement. 3102(A)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF GEOLOGICAL SCIENCES

LECTURESHIP

Applications are invited for a lectureship with special interest in sedimentology. This is a newly established post and will be tenable from 1st October 1979. Salary will be in the range £4,333 to £8,992 (October Scales) plus superannuation. Starting salary will depend on age, experience and qualifications.

Further particulars are available from the Assistant Registrar, Science and Engineering, University of Birmingham PO Box 363, Birmingham B15 2TT, to whom applications (3 copies) including full curriculum vitae and naming three referees should be sent by Friday 21st September 1979.

Pleae Quote ref: NG5. 3086(A)

Physicists

For Rutherford Laboratory's High Energy Physics Programme

The Rutherford Laboratory is one of the Science Research Council's leading centres. The Laboratory maintains an active experimental programme based principally on Accelerators at the European Organisation for Nuclear Research (CERN) in Geneva and at the Deutsches Electronen-Synchrotron (DESY) in Hamburg.

Their High Energy Physics Division now has two vacancies for young Experimental High Energy Physicists at either Senior Scientific Officer or Higher Scientific Officer level.

Applicants should be post-doctoral physicists with experience in the formation, running and analysis of high energy physics experiments.

A certain amount of time would be spent abroad at CERN or DESY, and candidates will be required to work in collaboration with Physicists, both from British Universities and from abroad.

Depending on qualifications and experience, salaries will be in the range:-

Depending on qualifications and experience, salaries will be in the range: – Senior Scientific Officer: £6,290-£8,415 (£6,780-£9,315 from 1st. Jan. 1980). Higher Scientific Officer: £5,060-£6,650 (£5,455-£7,210 from 1st. Jan. 1980).

There is a contributory pension scheme, generous leave and sick leave allowances.

Application forms are available from Jane Griffiths of the Personnel Group. Telephone her on Abingdon (0235) 21900 Ext. 510, or write, quoting reference VN822 Rutherford Laboratory, Chilton, DIDCOT, Oxon OX11 0QX.

Closing date for applications 21st September 1979.

3097(A)

POST-DOCTORAL POSITION IN ELECTRON DIFFRACTION CRYSTAL STRUCTURE ANALYSIS

A position is available after November 1, 1979 for research on the development and application of electron diffraction techniques for organic crystal structure analysis (small molecules and linear polymers). Quantitative use of transmission e.d. data will include application fo the direct phasing technique used in X-ray crystallography with concomitant evaluation of the deleterious influence of n-beam dynamical interactions and crystal deformations on the success of such structural analysis. The applicant should have a background in diffraction physics and crystallography and should be able to operate an electron microscope.

Appointment initially for one year; probably renewable. Address applications with 3 references to D.L. Dorset, Molecular Biophysics Department, Medical Foundation of Buffalo, Inc., 73 High Street, Buffalo, New York 14203, U.S.A. W334(A)

FLOUR MILLING AND BAKING RESEARCH ASSOCIATION

ORGANIC CHEMIST

The Flour Milling and Baking Research Association carries out a wide range of research and service work for the Milling and Baking Industries and holds a number of research contracts from the Ministry of Agriculture, Fisheries & Food. The laboratories are situated in an attractive semi-rural area on the edge of the Chilterns with ready access to London.

A **GRADUATE ORGANIC CHEMIST** is required to join a small team studying the composition and properties of cereal bran and germ. The successful candidate will initially be involved in the development and application of methods of analysis of complex carbohydrates.

The post is permanent and superannuated, and will be graded Scientific Officer (£3,194 to £4,767) or Higher Scientific Officer (£4,530 to £5,904), according to qualifications and experience.

Further details and an application form may be obtained from Professor Brian Spencer, Flour Milling and Baking Research Association, Chorleywood, Rickmansworth, Herts. WD3 5SH. Tel: Chorleywood (STD 092 78) 4111. 3135(A)

Horticultural Centre Loughgall Higher Scientific Officer

£4,727 – £6,211

(£5,097 – £6,737 from 1st January 1980)

Applications are invited for a pensionable post in the Horticultural Centre of the Department of Agriculture, situated at Loughgall, Co Armagh.

DUTIES

The person appointed will be responsible for chemical and biological services associated with experimental work within horticulture. The duties will also include the direction and development of the recently constructed centralised laboratory unit.

QUALIFICATIONS

Applicants must be under 30 years of age at 31 December 1979 and possess a first or second class Honours Degree in Chemistry, Biochemistry or an appropriate relevant subject and have at least 2 years' appropriate post graduate experience.

A knowledge of commercial horticulture is desirable but not essential.

Exceptionally, applications may be considered from candidates over the age limits who have specialised experience.

The Civil Service Commissioners may decide to interview only those applicants who appear from the information available (including level of academic attainment and experience) to be best qualified.

SALARY

Higher Scientific Officer £4,727 – £6,211.

Starting salary will be related to qualifications and experience.

There are prospects of promotions to Senior Scientific Officer (£5,876 – £7,864) and Principal Scientific Officer (£7,534 – £9,646). The aforementioned salary scales are subject to review from 1st January 1980.

Please write or telephone for an application form quoting job reference SB 267/79/N to the Civil Service Commission, Rosepark House, Upper Newtownards Road, Belfast BT4 3NR (telephone Dundonald 4585 ext 256). Completed forms must be returned to arrive not later than 20th September 1979.

3128(A)

NORTHERN IRELAND CIVIL SERVICE

UNIVERSITY OF OXFORD
in association with
Lady Margaret Hall

UNIVERSITY LECTURESHIP IN INORGANIC CHEMISTRY

Applications are invited for the above post to be filled from 1 October 1980 or earlier if possible. Stipend according to age on the scale £4,232 to £9,000. The successful candidate may be offered a Tutorial Fellowship in Inorganic Chemistry by Lady Margaret Hall associated with a lecturership at Brasenose College, both college appointments being open to men and women.

Details of the University and college appointments may be obtained from Professor J.B. Goodenough, Inorganic Chemistry Laboratory, South Parks Road, Oxford, OX1 3QR, to whom applications (6 copies) should be sent by *1 November 1979.* 3114(A)

THE UNIVERSITY OF MANCHESTER. Research Technician (grade 5) required to work in the Department of Anatomy. Applications are invited for the post of research technician to work in the area of experimental neurology. Applicants must hold HNC or equivalent and have at least 8 years' laboratory experience. Competence in a wide range of modern techniques in histology and microscopy including autoradiography is essential. Previous experience in research work is required and a working knowledge of the use of neuroanatomical, neurophysiological or neuropharmacological research techniques would be a considerable advantage. Salary on the interim scale £3,700 to £4,320 p.a. together with further comparability payments and subject to overall review as from 1st October 1979. Applications giving details of age, qualifications, experience and the names of two referees should be sent to Professor P.F. Harris, Department of Anatomy, Medical School, University of Manchester, Manchester M13 9PT, by 30th September 1979. 3109(A)

ROYAL POSTGRADUATE MEDICAL SCHOOL
DEPARTMENT OF CLINICAL PHARMACOLOGY

SENIOR RESEARCH OFFICER (Postdoctoral)

with experience of cell culture and protein purification is required for two years to join a collaborative project between the Central Toxicology and Coporate Laboratories of ICI Ltd. and the Department of Clinical Pharmacology, Royal Postgraduate Medical School. The successful applicant will join a multidisciplinary team working on the isolation and characterisation of multiple forms of cytochrome P-450 from human and animal tissue.

Salary on range 1A for non clinical research staff.

Application forms and further particulars may be obtained from the Personnel Office, Royal Postgraduate Medical School, 150 Du Cane Road, London W12 0HS quoting reference number 20/ICI/N. 3094(A)

UNIVERSITY OF BRISTOL
BIOMECHANICS

Assistance is required for a project between the University and the S.W. Regional Hospitals to investigate the mechanics of total hip replacement. The experimental approach will initially involve strain gauge instrumentation of the femur and the femoral prosthesis in an animal model in vivo. The appointment will be as

RESEARCH ASSISTANT 1A

Preference will be given to those with a PhD, or other post graduate experience.

Salary from £4,232 p.a. depending on experience. (Scale subject to revision with effect from 1st October, 1979).

Applications, together with a c.v. and the names of two referees to Dr L.E. Lanyon, School of Veterinary Science, Park Row, Bristol BS1 5LS by September 22nd. 3101(A)

DEVELOPMENT BIOLOGIST — an assistant professorship (tenure track) is available starting September 1980. Primary duties include teaching and research in molecular and cellular aspects of development. Applicants should send curriculum vitae, reprints, and three letters of recommendation to: Development Search Committee Chairperson Division of Biological Sciences, University of Michigan, Ann Arbor, Michigan 48109, by November 10, 1979. A non-discriminatory affirmative action employer. W343(A)

UNIVERSITY OF MALAYA

Applications are invited for the following post:

FACULTY OF SCIENCE

Post of Lecturer in the Department of Geology in the field of Structural Geology or Palaeontology.

Qualification: Candidates must possess at least a Master's degree in the required field; or PhD in the required field.

Salary scales (approx. stg. equiv.): Lecturer, £3,602 × 168 — 3,939/4107 × 168—4,443/4780 × 280 — 6,182/Review Point — £6,462 × 336 — 6,799.

Further particulars and application forms are obtainable from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

The closing date for the receipt of applications is 30 September, 1979.

3106(A)

UNIVERSITY OF LONDON KING'S COLLEGE
DEPARTMENT OF GEOLOGY

Applications are invited for the post of

TUTORIAL STUDENT

in the Department of Geology, tenable from 1st October, 1979 until 30th September, 1980 in the first instance but renewable for two further years. Applicants must be, or expect to be, graduates and will be required to read for a higher degree by research.

The award amounts to £2,500 per annum with free tuition in the College, in return for a limited amount of tutorial or demonstration assistance in the Department.

Application forms and conditions of appointment from: The Assistant Registrar, King's College, Strand, London WC2R 2LS, to whom completed applications should be returned as soon as possible. 3107(A)

UNIVERSITY OF MANCHESTER

RESEARCH ASSOCIATE IN MEDICAL BIOCHEMISTRY

Applictions invited from post-doctoral candidates for this post (available for three years) to work on glycoproteins and proteoglycans in collagenous structures of blood vessels. Some experience in the fields of connective tissue glycoconjugates, immunolocalisation or cell culture would be an advantage. Starting salary in the range £4,333 to £4,910 p.a.

Applications with full curriculum vitae and the names of two referees should be sent, as soon as possible, to Professor D.S. Jackson, Department of Medical Biochemistry, University of Manchester Medical School, Manchester, M13 9PT.

3142(A)

POST-DOCTORAL RESEARCH ASSISANT required in Department of Microbioloy to work on a three-year M.R.C. project on latency of human papovaviruses. Suitable for biochemist or virologist with experience in nucleic acid research. Salary not less than £4,262 plus £502 London Allowance for suitably qualified person. For further information telephone Dr McCance (01-407 7600 ext. 3376). Apply in writing, with full curriculum vitae, to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. M.C.5. 3078(A)

UNIVERSITY OF BRISTOL

CHAIR IN PHYSIOLOGY

The University invites applications for appointment to the Chair in Physiology which becomes vacant on the appointment of Professor T.J. Biscoe to the Jodrell Chair of Physiology at University College, London. The appointment will carry with it Headship of the Department for a five year period in the first instance.

A clinical qualification is desirable but not essential. Candidates are invited to submit applications, including the names of three referees, not later than 12th October, 1979, to the Registrar and Secretary of the University, Senate House, Bristol, BS8 1TH, from whom further particulars may be obtained. 3134(A)

LEEDS AREA HEALTH AUTHORITY (TEACHING)
EASTERN DISTRICT

ST JAMES'S UNIVERSITY HOSPITAL

SCIENTIFIC OFFICERS

Applications are invited from graduates with an Honours degree in one of the Biological Sciences for additional posts of Scientific Officer in the Regional Cytogenetic Unit established at this hospital, undertaking investigations required for patients within a wide area in and around Leeds.

Previous experience in cytogenetics is desirable but not essential.

Application forms & job descriptions available from the Personnel Office — General Sector, Gledhow Wing, St James's University Hospital, Beckett Street, Leeds LS9 7TF. Tel. Leeds 33144, ext. 5103. 3117(A)

RESEARCH APPOINTMENT

he European Economic Community is to upport a European programme of esearch on Dutch elm disease. As part of his programme the Forestry Commission s undertaking a wide ranging study of the ariability of the causal fungus *eratocystis ulmi* and requires a Scientific fficer at the Forestry Commission esearch Station at Farnham, Surrey to rovide technical assistance with aboratory studies on isolates of *C. ulmi* rom various parts of Europe and lsewhere.

Conditions: Period appointment for 2 ears with a possible extension to a third ear.

Qualifications: A degree in a biological r botanical subject and preferably xperience or special interest in mycology.

Age: Under 27 years of age on 1 December, 1979.

Salary: Within the range for Scientific fficer (£3,289 to £5,085) depending upon ge and experience.

Closing date for applications: pplication forms and further details may e obtained from Mr A.J. Freeman, ersonnel Branch, Forestry Commission, 31 Corstorphine Road, Edinburgh EH12 AT. Completed application forms should e returned no later than 27th September, 979. 3120(A)

UNIVERSITY OF BRISTOL

Cosmic Ray Research

pplications are invited for three posts of

RESEARCH ASSISTANT

ach of 24 months duration, for work ithin the cosmic ray studies group under rofessor P.H. Fowler, FRS. These posts ill be concerned with experiments to easure the high energy component of the ltra-heavy cosmic rays and the 'anomalous'' component of the low nergy cosmic rays.

Experience with nuclear or spacecraft strumentation, especially the use of drift hambers and microprocessor based data cquisition sytems, would be appropriate.

Salaries will be on the scales for research taff grades 1A (2 posts) £4,333 × £289 and B (1 post) £3,775 × £280. (Scale effective rom 1st October, 1979 and subject to urther review).

Applications, naming two referees and iving details of education and relevant xperience should be made by 20th eptember, 1979 to Dr R.M. Redfern, .H. Wills Physics Laboratory, Tyndall venue, Bristol BS8 1TL. Telephone ristol 24161 ext 110, from whom further nformation can be obtained. 3047(A)

UNIVERSITY OF THE WITWATERSRAND

Johannesburg

DEPARTMENT OF GEOLOGY

Applications are invited for appointment to the following posts:

CHAIR OF MINERAL GEOCHEMISTRY

The successful applicant for the above teaching and research position will be responsible for the co-ordination and advancement of teaching courses in geochemistry in the department, and, in addition to pursuing his/her own research projects, will be encouraged to participate in co-operative research programmes in a wide range of interdisciplinary Earth Science projects, and to collaborate with the substantial group of geochemists in other sections of the University. The Department is well equipped with an experimental geochemical laboratory and XRF, XRD and wet-chemical analytical facilities; a modern ARL-SEMQ electron microprobe has recently been installed, and is operated and maintained by an electron microprobe technical officer.

The starting salary will be determined according to qualifications and experience in the range R15,000 to R18,000 per annum. In addition, the appointment carries a non-pensionable supplementation of R4,000 per annum.

LECTURESHIP IN ENGINEERING GEOLOGY

The principal duties attached to this post include assisting in the teaching of a one-year introductory course in Geology to Engineering students, and participation in more advanced courses in Engineering Geology in the newly-introduced four-year BSc (Eng) degree course in this field.

The starting salary will be determined according to qualifications and experience in the range R8,100 to R13,200 per annum.

The University's policy is not to discriminate in the appointment of staff or the selection of students on the grounds of sex, race, religion or colour. Further particulars relating to this practice and to the above posts are included in an information sheet obtainable from the London Representative, University of the Witwatersrand, Chichester House, 278 High Holborn, London WC1V 7HE, or from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, 2001 South Africa, with whom applications should be lodged by 28th September, 1979. 3110(A)

RESEARCH & DEVELOPMENT VACANCIES

Vacancies exist in the Research & Development department of a large international company for Materials Scientists and Applied Physicists to work in the areas of Physics, Optics and Electro-optics in a small but expanding Research Team. Candidates must possess a BSc in Physics or Applied Physical Sciences, or a higher qualification, and will probably be new or recent graduates with an aptitude for experimental and practical work.

There is also an opening for an Applied Mathematician or Theoretical Physicist with at least two years' experience in mathematical modeling, using both high and low-level programing techniques. Many of the problems are time constrained and there will be a requirement for the development of real-time algorithms in addition to solutions for complex geometrical problems.

This is an unusual opportunity to join a unique organisation offering excellent conditions of employment with opportunities for overseas travel from time to time. These posts will be based initially in Central London although the R&D department will be moving to premises to the West of London in the future.

Please write with Curriculum Vitae to:

M. H. Boorman,
2, Charterhouse Street,
London, EC1N 6RX.

South London College

formerly Norwood Technical College,
founded 1859
Main Building: Knights Hill SE27 0TX
Tower Bridge Branch: Tooley Street SE1 2JR

Department of Physical Sciences

Research Assistantship in Geology

The College has a Research Assistantship in Geology available from 1 October 1979, initially for a period of one year but extendable to a maximum of three (depending on satisfactory progress) to enable a PhD to be obtained if appropriate, to be based in the Geology section of the Department which is located at Knights Hill.

Applicants should have a good Honours degree in Geology or Earth Sciences.

The successful applicant will have the opportunity to research in volcanology, or in the petrology and mineralogy of volcanic rocks, or in the magmagenesis of volcanic rocks.

Salary Scale: £2,613 × £87(2) – £2,787 (under review) plus London Allowance of £474.

Application forms, returnable within 14 days of the appearance of this advertisement, obtainable from the Clerk to the Governors at the main building. Enclose self-addressed envelope, not smaller than 10" × 7" if a Prospectus and any further particulars are required.

ilea INNER LONDON EDUCATION AUTHORITY 3118(A)

LABORATORY SCIENTIFIC OFFICER required in Department of Microbiology to work on a three-year M.R.C. project on latency of human papovaviruses. Experience in biochemical aspects of virology essential. Salary for qualified Laboraory Scientific Officer not less than £3,261 (under revision) plus £354 London Weighting. Apply in writing, stating age and giving details of qualifications and experience, to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. M.C.4. 3077(A)

UNIVERSITY OF OXFORD

in association with
St. Catherine's College

TEMPORARY TEACHING APPOINTMENT

in Inorganic Chemistry or Chemical Crystallography

Applications are invited for the above appointment on the university lecturer scale, £4,232 to £9,000 according to age, for 5 years to cover a temporary secondment from 1 April 1980. The successful candidate may be offered a Teaching Appointment in Inorganic Chemistry by St. Catherine's College for the duration of the university appointment.

Details of the college and university appointments may be obtained from Professor John B. Goodenough, Inorganic Chemistry Laboratory, South Parks Road, Oxford, OX1 3QR, to whom applications (5 copies) should be sent by 1 November, 1979. 3113(A)

X-RAY CRYSTALLOGRAPHER Research Associate to conduct x-ray diffraction studies on liquid crystals in well equipped laboratory. Required PhD or equivalent experience. Salary: $11-15,000 annually, depending on qualifications. Reply to Dr Leonid V Azaroff, Director, Institute of Materials Science, University of Connecticut, Storrs, CT 06268 before October 22, 1979. An Equal Opportunity Employer. XW328(A)

UNIVERSITY OF HONG KONG

CHAIR IN CLINICAL PHARMACOLOGY

Applications are invited for the above-mentioned post in the Department of Medicine. Candidates should have qualifications of M.R.C.P. or equivalent with appropriate experience in patient management and the subject required.

Annaul salary (currently under review) (superannuable) will be within the professiorial range and not less than HK$197,280 (£1 = HK$11.50 approx.).

At current rates, salaries tax will not exceed 15% of gross income. Housing at a rental of 7½% of salary, education allowances, long leave and medical benefits are provided.

Further particulars and application forms may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or the Assistant Secretary (Recruitment), University of Hong Kong, Hong Kong.

Closing date for applications is *1 October 1979.* 3098(A)

The Queen's
University of Belfast

RESEARCH ASSISTANT

Palaeoecology Laboratory

Applications are invited from graduates in physical or biological sciences for this Science Research Council financed post tenable for three years. The successful applicant will be required to carry out tree-ring dating and timber sample preparation for which full training will be given. The job demands an exacting standard of accuracy and will involve a high proportion of microscope work. A driving licence would be an advantage.

Commencing salary in the range £3,777 to £4,335.

Curriculum vitae and the names and addresses of two referees should be sent to the Personnel Officer, The Queen's University of Belfast, BT7 1NN, Northern Ireland. Closing date: 21st September, 1979.

3119(A)

MEDICAL RESEARCH COUNCIL

National Institute for Medical Research

IMMUNOLOGIST

A young postdoctoral immunologist is required by the Laboratory for Leprosy and Mycobacterial Research to investigate immunity of mycobacterial infections. It is proposed that the person appointed will study particularly the immunological control of the growth of mycobacteria in tissue culture and in animals. The appointment will be for up to three years and will be in the salary range £4,940 to £6,627 per annum according to age and qualifications, plus £502 p.a. London allowance. Superannuation provision.

Applications, giving details of qualificaions, experience and the names of two professional referees, should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA before 31st October 1979, quoting reference LM. 3130(A)

ST. HELIER HOSPITAL CARSHALTON, SURREY

SCIENTIFIC ASSISTANT

DERMATOLOGY DEPARTMENT

With post graduate experience in either Biochemistry or Immunology to work on skin diseases including malignancy.

Apply by 28th September to Dr E.L. Rhodes at above address.

SIMON FRASER UNIVERSITY

Burnaby, British Columbia

DEPARTMENT OF CHEMISTRY

APPOINTMENT IN BIOCHEMISTRY

Applications are invited for a tenure track appointment at the assistant professor rank, preferably with specialization in the area of macro-molecular biochemistry, starting September 1, 1980. The appointment is subject to budgetary approval. The successful applicant will be required to teach graduate and undergraduate courses in biochemistry and to establish a vigorous research program.

The current base of the assistant professor rank is $19,720 per annum.

Applications, including curriculum vitae, a concise statement of proposed research and the names of three referees, should be sent by December 31, 1979 to: Dr. C.H.W. Jones, Chairman, Department of Chemistry, Simon Fraser University, Burnaby, BC, Canada V5A 1S6. W319(A)

UNIVERSITY OF DUBLIN
Trinity College

LECTURER IN PHARMACEUTICS

Applications are invited for the post of Lecturer in Pharmaceutics in the School of Pharmacy, Trinity College, Dublin. Preference will be given to pharmacy graduates with suitable experience in Pharmaceutical Technology or Physical Pharmaceutics.

Salary Scale: £5,078 to £10,038 p.a.

Appointment is likely to be made within the range £5,078 to £6,462 p.a. There is a non-contributory pension scheme.

Application forms and further particulars relating to this post may be obtained from:

The Establishment Officer
West Theatre
Trinity College
Dublin 2

to whom completed applications should be sent *not later than 25th September, 1979.*

3104(A)

FERMENTATION MICROBIOLOGIST

We are a large forest products R&D organisation, and are expanding our efforts on the conversion of wood residues to valuable products. Applicant should have a good honours degree, and preferably a PhD, in one of the biological sciences, together with specialised knowledge of fermentation processes, ideally in the area of biochemical engineering.

Duties will be to grow microorganisms on wood-based materials in laboratory fermenters, including continuous culture equipment. He will work closely with chemists on suitable pretreatments of the wood substrate and will be expected to devise techniques for screening, collecting and optimizing the yield of a variety of end products.

Salary open; fringe benefits generous. For further information please write to: Mr I B Flann, Forintek Canada Corp, 800 Montreal Road, Ottawa, Ontario, K1G 3Z5, Canada. W330(A)

UNIVERSITY COLLEGE LONDON

READERSHIP IN PROBABILITY AND STATISTICS

The Senate invites applications for th above Readership in the Department o Statistics and Computer Science particularly from persons with researc interests in data analysis. Salary at a agreed point on the scale £8,698 to £10,77 (from October 1979) plus £502 Londo Allowance.

Applications (10 copies) must b received not later than 19 October 1979 b the Academic Registrar (N), University o London, Senate House, London WC1E 7HU, from whom further particular should first be obtained. 3096(A)

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

A MEDICAL LABORATORY SCIENTIFIC OFFICER

is required to assist for up to 18 months in a WHO-funded programme on *in vitr* culture of human filariae using insect cel lines. Candidates must hold an HNC in a relevant discipline.

Applications, in writing, giving ful career details and naming two referees should be sent to Secretary (A1). 3143(A)

THE UNIVERSITY COLLEGE OF WALES ABERYSTWYTH

Department of Agricultural Botany

Applications are invited for the post of Postgraduate Research Assistant tenable from 1 October, 1979 for a period of three years to work on Nuclear DNA variation in higher plant species. Candidates should have a Degree in Biology with training in Genetics or Biochemistry.

Salary from £3,775 per annum on Range IB of the Research and Analogous Scales.

Application forms can be obtained from The Registrar, (Staffing Office), The University College of Wales, Old College, King Street, Aberystwyth, SY23 2AX (Tel. 0970 3177) to whom completed forms hould be returned no later than Monday, 7th September, 1979. 3127(A)

ASTRONOMER ROYAL FOR SCOTLAND REGIUS CHAIR OF ASTRONOMY UNIVERSITY OF EDINBURGH

he Secretary of State for Scotland invites pplications for the office of Astronomer oyal for Scotland and for the post of egius Professor of Astronomy in the University of Edinburgh. The Science esearch Council will participate in the election of the successful applicant, so hat he/she may be appointed by the ouncil as Director of the Royal bservatory, Edinburgh. It is hoped that he person appointed will assume respon-bilities with effect from 1st October, 980.

Further particulars may be obtained om the Secretary, Scottish Education epartment, 8 George Street, Edinburgh H2 2PF to whom 4 copies of applications, cluding the names of three referees, hould be sent not later than Monday, 8th ctober 1979. 3044(A)

POSTDOCTORAL RESEARCH ASSOCIATE

o work on the organisation and anscription of the genes for mammalian ow molecular weight RNAs, or on the unction of these RNA species. Recent hD with background in molecular biology r biochemistry preferred.

Send C.V. and names of three references o: Dr. George L. Eliceiri, Cell Biology ivision, Department of Pathology, St. ouis University School of Medicine, 1402 Grand, St Louis, Missouri 63104, U.S.A. n Equal Opportunity Employer M/F/H. W331(A)

FRESHWATER IOLOGICAL ASSOCIATION

SENIOR ANALYTICAL CHEMIST

acancy at Windermere Laboratory. uties to include: general co-ordination of alytical programme and development of ose liaison with biological staff; routine alysis; development of new methods; ersight of radiochemical laboratory, cluding training of scientific staff in chniques and safety.

Candidates should hold a first degree or evant industrial qualification and have nsiderable practical experience. The nsionable post is graded HSO/SSO and arting salary would be £5,800 or above pprox. 10% additional pay award is due n January 1980).

Further details and application forms ay be obtained from: The Secretary, eshwater Biological Association, The rry House, Ambleside, Cumbria LA22 P. Closing date 14th September 1979. 2979(A)

UNIVERSITY OF NOTTINGHAM

Applications are invited for the post of

RESEARCH ASSISTANT

from recent graduates in a Biological Science to investigate the pharmacology of cultured mouse neurones. This project is supported by MRC and will be under the direction of Professor P.N.R. Usherwood.

Appointment for one year in the first instance (with a possible extension for two years) from October 1979 or as soon as possible thereafter. Salary on Scale £3,883 to £4,382.

Applications, including full curriculm vitae and names of two academic referees to: Professor P.N.R. Usherwood, Zoology Department, Nottingham University, University Park, Nottingham NG7 2RD. 3081(A)

UNIVERSITY OF OXFORD

TECHNICIAN IN ELECTRON MICROSCOPY

A Grade 4 technician is required to work on a three year ARC funded project concerned with the development of techniques for the preparation of biological specimens for high voltage electron microscopy. It is an unusual project and there is plenty of scope for initiative. Salary scale in the range £3,432 to £3,950, increasing in April, 1980, to £3,641 to £4,191.

Applicants should preferably have some EM experience and hold ONC, C&G, or equivalent qualifications, but inexperienced candidates will be considered. Further particulars may be obtained from The Administrator, Department of Agricultural Science, Parks Road, Oxford, OX1 3PF, to whom applications, including full curriculum vitae and names and addresses of two referees, should be sent as soon as possible. 3138(A)

THE UNIVERSITY OF BRITISH COLUMBIA

DEPARTMENT OF CHEMISTRY

ASSISTANT PROFESSORSHIP

Applications are invited from well qualified candidates for a position at the rank of Assistant Professor which will become vacant as the result of the retirement of a Faculty member on June 30, 1979. Persons with research and teaching interests in any area of chemical science are eligible to apply.

Applications consisting of a curriculum vitae, a list of publications and the names and addresses of three referees should be sent to the undersigned before November 30th, 1979. This position is open to both male and female applicants.

Professor Charles A. McDowell, Department of Chemistry, University of British Columbia, 2075 Wesbrook Mall, Vancouver, British Columbia, Canada, V6T 1W5. W337(A)

THE UNIVERSITY OF LEEDS

Department of Plant Sciences

Applications are invited for a post of

DEMONSTRATOR

in the above Department for a fixed period of one year from 1 October 1979. Applicants should have a good honours degree in a Biological Science.

Salary on the IB scale for Other Related Staff: £3,775 to £6,355 (under review), according to age, qualifications and experience.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 53/14/D. Applications should be submitted as soon as possible and not later than 21 September, 1979. 3125(A)

News Editor

A senior vacancy exists for News Editor of *Nature*, the international and interdisciplinary journal for scientists and science policy-makers. This vacancy has occurred with the move of the present News Editor to the new post of *Nature*'s Chief European Correspondent.

The News Editor will have responsibility under the Editor for about twelve news pages in each week's issue covering policies, events and personalities of concern to, or influenced by, the international scientific community.

He/she will have the full time services of an American and a European staff correspondent as well as help with lay-out and sub-editing.

The successful candidate will have several years experience as a journalist, a strong interest in international affairs and an enthusiasm for planning, co-ordinating and commissioning. Science background not essential but familiarity with the demands of professional/academic readership an advantage.

Write as soon as possible to — The Editor, *Nature*, Macmillan Journals Limited, 4 Little Essex Street, London WC2R 3LF, enclosing a curriculum vitae.

3048(A)

M MACMILLAN

ASSISTANT PROFESSOR OF MICROBIOLOGY. The Department of Microbiology and Immunology, Washington University School of Medicine invites applications from highly qualified individuals for an appointment as Assistant Professor. Applicants should have PhD or MD degrees, 2-5 years of post-doctoral research experience and a commitment to medical and graduate student teaching. Teaching competence should be in pathogenic microbiology; research interests should be in microbiology. Send curriculum vitae, brief description of research plans and names of three referees to Dr Joseph M Davie, Department of Microbiology and Immunology, Washington University School of Medicine, St Louis MO 63110 by November 1, 1979. Equal Opportunity and Affirmative Action Employer M/F/H. W339(A)

THE LONDON HOSPITAL MEDICAL COLLEGE (University of London)

RESEARCH TECHNICIAN

Required in the Medical Unit to assist in M.R.C. supported project on hypertension.

The post is for a maximum of two and half years. Previous laboratory experience is expected and experience in steroid immunoassay and/or catecholamine assay would be an advantage. Candidates should have HNC, MIBol, B.Sc. or equivalent.

Initial salary £3,261 + £354 London Allowance per annum (under review).

Enquiries to Dr H.L.J. Makin (01-247-0644, Ext.71). Applications to the Secretary, The London Hospital Medical College, Turner Street, London E1 2AD, quoting ref. RTMU/9/79. 3084(A)

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

DEPARTMENT OF BIOCHEMISTRY

POST-DOCTORAL RESEARCH ASSISTANT IN MOLECULAR BIOLOGY

Applications are invited for the above position to work on the genome organisation and expression of a plant virus with a circular single-stranded DNA genome. The investigation is a prelude to utilisation of the virus DNA as a transforming vehicle for the genetic modification of plant cells. Experience in some aspect of nucleic acid or protein biochemistry would be desirable. The post, which is supported by the science research council, is available for a maximum of three years, with a starting salary on research grade 1A within the range £4,260 to £4,805 p.a. To be reviewed 1/10/79., plus London allowance of £502 p.a.

Applications including curriculum vitae and names and addresses of two referees should be sent to Dr K.W. Buck, Department of Biochemistry, Imperial College of Science and Technology, London SW7 2AZ. 3027(A)

APPOINTMENTS VACANT

ODENSE UNIVERSITY
Denmark

Applications are invited for a position as lecturer at the Department of Molecular Biologi.

The new lecturer is supposed to participate in the plasmid group at the department. The research program of this group is concentrated on the replication (particularly control of replication) and biological importance of plasmids. Consequently, we are particularly interested in applicants with experience in molecular, biochemical, genetic, and physiological studies of bacteria.

The new member of the department is supposed to teach molecular biology and microbiology at all levels.

Enquires to Dr Kurt Nordström, Department of Molecular Biology, University of Odense, Campusvej 55, DK-5230 Odense M, Denmark. Telephone (09) 158600, extn. 2375. The new lecturer is expected to be able to teach in Danish after a few years. A professional selection committee will discuss the applications and their recommendation will be sent out to all applicants in its complete form.

Conditions of employment as provided by an agreement between the Ministry of Finance and the trade union of the applicant preferred.

Application in 3 copies, marked "position nr. 936" including a curriculum vitae, information of teaching experience, reprints of recent publications, and the names of referees should be sent (in triplicate) to: Odense universitet, journalkontore, Campusvej 55, DK-5230 Odense M, not later than Oktober the 4th, 1979. W346(A)

BIOCHEMIST

BIOCHEMICAL PHARMACOLOGIST

PROTEIN CHEMIST

To work on purification of enzymes that metabolize peptides and on enzyme inhibitors, as postdoctoral fellow or as visiting scientist, immediately.

Please contact Norene Ross, Secretary, Department of Pharmacology, University of Texas Health Science Center, Dallas, Texas 75235. W347(A)

KING'S COLLEGE LONDON
DEPARTMENT OF PHYSICS
LABORATORY TECHNICIAN GRADE 5

Responsibilities include developing, constructing and modifying apparatus for teaching requirements and student projects etc; maintenance, servicing and repairing of equipment and the preparation of graphs, blueprints and engineering drawings. The post also involves the training of juniors and some supervision of other technical staff. Applicants should have suitable qualifications and experience. Salary on scale £4,224 p.a. inclusive rising to £4,844 p.a. (under review). 5 weeks annual holiday. Contributory pension scheme. Interest-free loans for annual rail season tickets.

Apply in writing with full details to The Head Clerk (Ref. 217835/N), King's College London, Strand, WC2R 2LS.

3105(A)

FELLOWSHIPS and STUDENTSHIPS

UNIVERSITY OF ESSEX
DEPARTMENT OF PHYSICS
SRC POSTDOCTORAL RESEARCH FELLOWSHIP
Theory of Surface Excitations on Solids and Liquids

Applications are invited for this three-year fellowship to commence in January 1980 or as soon as possible thereafter. The initial salary will be on one of the first three points of the 1A scale (currently £4,333 to £7,521).

The successful candidate will work with M.G. Cottam, R. Loudon and D.R. Tilley on the theories of various kinds of surface excitation, including magnetic, electronic and vibrational surface waves on solids, and surface ripples on liquids. The main aim of the work is the prediction and interpretation of the experimental light-scattering spectra of surface excitations. The techniques employed in the calculations include standard solid-state theory of spin waves, lattice vibrations and excitons, linear-response theory, light-scattering theory, and fluid mechanics; applicants should have prior research experience in at least one of these areas.

Applications by letter, including a curriculum vitae and the names and addresses of two referees, should be sent to Dr M.G. Cottam, Department of Physics, University of Essex, Colchester CO4 3SQ, from whom further particulars may be obtained, by 20 October 1979. 3088(E)

THE UNIVERSITY OF NEWCASTLE UPON TYNE
DEPARTMENT OF ORGANIC CHEMISTRY

Applications are invited for a

RESEARCH STUDENTSHIP

from persons, who have a good honours degree in Chemistry, to work on the synthesis of novel ß-lactam antibiotics. The value of the award will be at current SRC rates and the student will be expected to register for a higher degree.

Applications, together with the names of two referees, should be sent as soon as possible to Dr R.J. Stoodley, Department of Organic Chemistry, The University, Newcastle upon Tyne, NE1 7RU.

3080(F)

UNIVERSITY OF ST ANDREWS
Department of Biochemistry
ARC Postdoctoral Research Fellowship

Applications are invited for a postdoctoral Research Fellowship to investigate the role of intracellular proteinases in the regulation of enzyme levels in barley under the direction of Dr. J.L. Wray. The project will involve the identification and purification of proteinases and characterisation of their role in the degradation of nitrate reductase and nitrite reductase. Preference will be given to applicants with experience in enzyme purification and/or immunochemical techniques.

Starting salary up to Point 3 (£4,910 on Grade 1A of the national salary scales for research staff (at present under review), plus USS. The appointment will be for three years.

Applications (two copies preferably in typescript) including a curriculum vitae and the names of two referees should be sent by 1st October 1979 to the Establishments Officer, The University, College Gate, St. Andrews, Fife KY16 9AJ from whom further particulars may be obtained. 3116(E)

UCG Coláiste na hOllscoile Gaillimh

Department of Zoology
POST-DOCTORAL FELLOWSHIP QUANTITATIVE GENETICS

Applications are invited from suitably qualified candidates for appointment to the above position. The appointee will join a small team being assembled at Galway to study the application of genetics to the improvement of cultivated fish and shellfish. The Department runs its own shellfish hatchery at Carna, approximately 50 miles from Galway. The appointee will work in conjunction with the staff of the hatchery but he/she will be based at Galway.

Candidates should have a good Honours Degree in an appropriate subject (e.g. zoology, genetics) and PhD Degree or equivalent research experience.

The position offers scope for development of the candidate's own research interest within the overall programme of the genetics team. Previous training and experience in quantitative genetics highly desirable.

Letters of application should be **forwarded before 5th October 1979** to the undersigned from whom further details are available:

Prof. N.P. Wilkins, Ref. Quant. Genet.,
National University of Ireland,
University College,
Galway, Ireland.

Recruitment will commence on or before 2nd November, 1979.

3115(E)

EARTH AND PLANETARY SCIENCES

The Lamont-Doherty Geological Observatory of Columbia University invites scientists interested in any field of the earth and planetary sciences to apply for the following fellowships: two postdoctoral fellowships, each awarded for a period of one year (extendable to two years in special instances) beginning in September 1980 with a stipend of $18,500 per annum. Completed applications are to be returned by January 15, 1980.

Application forms may be obtained by writing to the Director, Lamont-Doherty Geological Observatory, Palisades, New York 10964. Award announcements will be made February 28, 1980 or shortly thereafter. W344(E)

SCIENCE RESEARCH COUNCIL
FELLOWSHIPS
and
OVERSEAS (NATO) FELLOWSHIPS AND STUDENTSHIPS

Applications for SRC Fellowships and Overseas (NATO) Fellowships and Studentships commencing in 1980/81 should be made to the Science Research Council, PO Box 18, Swindon SN2 1ET.

For application forms telephone:

Swindon (0793) 26222, Ext. 2172

Closing dates for applications:

Senior Fellowships	: November 30, 1979
Advanced Fellowships	: September 30, 1979
Postdoctoral Fellowships	: January 31, 1980
Industrial Visiting Fellowships	: Apply at any time
Overseas (NATO) Fellowships	
In Europe	: January 12, 1980 and May 10, 1980
Outside Europe	: January 31, 1980
Overseas (NATO) Studentships	: January 31, 1980

Senior Fellowships candidates, who wish to learn results a year in advance, should also apply by November 30, 1979 for awards commencing in 1981/82. 3099(E)

FELLOWSHIPS continued

THE UNIVERSITY OF BRITISH COLUMBIA
DEPARTMENT OF CHEMISTRY
POSTDOCTORAL RESEARCH POSITIONS

pplications are invited from well ualified candidates for one or two year ppointments as Postdoctoral Research ellows in the following fields: tmospheric photochemistry; Bioinrganic chemistry; Catalysis studies, iffusion and phase separation on rfaces; Catalysis using transition metal omplexes; Marine natural products; evelopment of New Synthetic Methods in rganic Chemistry; Electron impact and hotoelectron Spectroscopy including uger and ESCA studies; Electron paraagnetic, ENDOR, NOR, Mossbauer, icrowave, electronic and LEED ectroscopies; Flash photolysis and inetic Spectroscopy; Fluorocarbon hemistry; Homogeneous and Heteroeneous Catalysis; Immunochemistry or olysaccharides; Inorganic photochemtry and photophysics; Kinetic theory of ases applied to aeronomy and space ience; Lipid synthesis for NMR study of iomembranes; Mechanism of the tercalation of layered Structures; uonium Chemistry at TRIUMF: NMR d laser Raman spectroscopy of nuclear in labelled nucleic acids; Nonlinear ptical effects in organic solids at low mperature; Nuclear magnetic resonance udies of molecular motion; Organic Solid tate Reactions; Organometallic Phoshazene and Thiazyl Chemistry; Oxidion, use of coenzyme models, general id catalysis; Potential antiviral and titumor compound synthesis; Quantum emistry and Molecular Physics; adiation chemistry and solvated electron udies; Synthesis and study of organic etals; Theory of molecular relaxation and ansport properties; X-ray diffraction udies.

The minimum stipend for the first year ill be $11,880. A substantial number of eaching Postdoctoral Fellowships, with a inimum stipend of $14,000, are open to udents who have recently graduated and ave shown superior ability in research and holarship.

Send curriculum vitae, transcripts, and tters from three referees to the undergned, from whom further particulars may obtained. Professor C.A. McDowell, epartment of Chemistry, University of ritish Columbia, Vancouver, BC, V6T W5, Canada. W338(E)

INSTITUTE OF CANCER RESEARCH: A three year Fellowship is offered in the Division of Molecular Biology for a Post-Doctoral Scientist to work on the isolation and characterisation of non-histone chromosomal proteins from plants and lower eukaryotes. Salary in range £4,261 to £4,805 pa plus London Allowance of £502 pa. Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London, SW7 3NU, quoting ref. 300/G/13. 3122(E)

NUFFIELD FOUNDATION
ONE-YEAR SCIENCE RESEARCH FELLOWSHIPS

The Nuffield Foundation is offering to University Lecturers in Science (but not Mathematics) Departments a number of one-year research fellowships to be awarded competitively at the end of 1979 and to be held during the academic year 1980-81. The objective is to enable younger university lecturers to be freed from teaching and administrative duties for one academic year in the first instance; preference will therefore be given to applicants under the age of 40. Awards will cover the cost of replacement teaching and will include an allowance for research expenses.

The closing date is 15 October 1979 and further particulars may be had from the Director, Nuffield Foundation, Nuffield Lodge, Regent's Park, London NW1 4RS 3133(E)

STRANGEWAYS RESEARCH LABORATORY
Cambridge
POST DOCTORAL FELLOWSHIP

available for work on the causation of lung cancer by environmental and industrial metal particulates and the possible interaction of these with systemic agents. The project is based in Cambridge and involves collaboration with the Industrial Toxicology Unit of the Dept of Safety and Hygiene, University of Aston. Funding is provided by a 3 year grant from the Health and Safety Executive starting as soon as practical. MRC conditions of service, starting salary in the range £5,048 to £5,850 depending on age and qualifications. Applications (2 copies) from persons with good previous experience of the techniques of experimental pathology should be forwarded to Administrative Secretary, Strangeways Research Laboratory, Worts Causeway, Cambridge CB1 4RN, together with full c.v. and the names of two referees. 3124(E)

THE ROYAL SOCIETY
ROYAL SOCIETY METEOROLOGICAL OFFICE RESEARCH FELLOWSHIP IN DYNAMICAL METEOROLOGY

Applications are invited by the Council of the Royal Society for a

ROYAL SOCIETY METEOROLOGICAL OFFICE RESEARCH FELLOWSHIP IN DYNAMICAL METEOROLOGY

tenable in the department of atmospheric physics, University of Oxford. Candidates should supply the usual personal details and the names of two referees, together with a full description of the research proposed.

The appointment, which will be subject to the Society's general regulations governing research appointments, will be tenable for five years from a date to be mutually agreed in the academic year starting on 1 October 1979. The commencing salary which will depend on age and experience, will be within the scale £4,863 to £8,019 per annum, with appropriate superannuation benefits.

Applications should be made on forms to be obtained from The Executive Secretary, The Royal Society, 6 Carlton House Terrace, London, SW1Y 5AG, and should be received not later than 30 September 1979. 3083(E)

FELLOWSHIPS continued

ESO FELLOWSHIPS 1980-1981

The European Southern Observatory (ESO) intends to award up to six fellowships tenable in the ESO Scientific-Technical Center which from August 1980 will be located in Garching near München.
The main goals of the Center are as follows:
— to carry out a program of development of auxiliary instrumentation for the La Silla telescopes;
— to make studies in observational and theoretical astrophysics so that the observing facilities may be used in an optimal way;
— to provide data reduction facilities to users of the ESO instruments;
— to provide photographic facilities for atlases of the southern sky;
— to foster co-operation in astronomy and astrophysics in Europe.
Most of the scientists in the Center come from the Member States of ESO, but several are from other countries. At present, the Member States of ESO are: Belgium, Denmark, the Federal Republic of Germany, France, the Netherlands and Sweden. In addition to regular staff members, the Center comprises visiting scientists and post-doctoral fellows.
ESO facilities include the La Silla Observatory in Chile with its six telescopes in the range of 0.9 to 3.6m, as well as a 1m Schmidt and some smaller instruments. In Garching, extensive measuring, image processing and computing facilities will be available.
Applicants normally should have a doctorate. The basic monthly salary will be not less than DM2,991. The fellowships are granted for one year, beginning October 1, 1980, with reasonable possibilities for renewal for a second year. Applications should be submitted to ESO not later than December 31, 1979. Applicants will be notified by the end of February 1980. The ESO Fellowship Application form should be used and be accompanied by a list of publications. In addition, three letters of recommendation should be obtained from persons familiar with the scientific work of the applicant. These letters should reach ESO not later than December 31, 1979.
Enquiries, requests for application forms and applications should be addressed to:

ASSISTANTSHIPS

UNIVERSITY OF LEICESTER

Department of Biochemistry

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a postdoctoral research assistantship supported by the MRC to work with Dr D Critchley on cell surface changes and malignancy. The project is directed toward investigating the possible relevance of loss of complex glycolipids to other aspects of the malignant phenotype, including loss of fibronectin. Experience in cell culture and membrane biochemistry is desirable but not essential.

The appointment will commence as soon as possible; the post is most suited to candidates with at least 1 or 2 years postdoctoral experience, although recently qualified candidates will be considered. The salary will commence in the range of £4,333 to £5,199 depending on the candidate's age and experience.

Applications including curriculum vitae and the names of two referees should be sent to Dr D Critchley, Department of Biochemistry, University of Leicester, Leicester LE1 7RH. 3126(P)

UNIVERSITY OF DURHAM

DEPARTMENT OF ZOOLOGY

POST-DOCTORAL BIOCHEMIST/PHYSIOLOGIST

required for a three year Senior Research Assistantship tenable as soon as possible, to investigate the control of lipogenesis and membrane biogenesis during hormone induced cell differentiation in avian liver. Research experience in biochemistry or a related field is essential and experience of cell culture/enzymology/immunochemistry would be an advantage. Initial salary in the range £4,333 to £4,910 per annum within Range 1A plus superannuation.

Applications (3 copies) naming three referees should be sent by 28 September 1979, to the Registrar and Secretary, Science Laboratories, South Road, Durham, DH1 3LE, from whom further particulars may be obtained. 3064(P)

ANNOUNCEMENTS

HEISER PROGRAM FOR RESEARCH IN LEPROSY

Beginning postdoctoral research fellowships, small research grants, visiting research awards available. Stipends range from $12,000 to $15,000. Applicants should have MD, PhD, or equivalent degree.

Applications by February 1 for awards to be activated June-December, 1980. For information write: Heiser Program for Research in Leprosy, 450 East 63rd Street, New York, NY 10021, USA. W345(G)

COURSES

EUROPEAN MOLECULAR BIOLOGY ORGANISATION

Course on:

TERATOMAS

University of Glasgow,
17-29 March 1980
Organisers: M L Hooper (Glasgow)
C F Graham (Oxford)

Lectures and practical work will cover the following main topics:

Production and properties of mouse teratomas *in vivo*, differentiation of teratomas *in vitro*, embryology and genetics of the mouse, embryo culture, blastocyst injection, somatic cell genetics, cell surface, polyacrylamide gel techniques, histology, immunological techniques, erythroid differentiation. Guest lecturers will include L C Stevens (Bar Harbor), G R Martin (San Francisco), M J Evans (Cambridge), B L M Hogan (London), S Povey (London), P Goodfellow (Oxford), M Osborn (Göttingen).

Participation is open to postdoctoral and final year predoctoral workers from EMBO countries. Course fee £50 including bed and breakfast accommodation. Number of places limited to 20. A small number of EMBO fellowships will be available for applicants who could not otherwise attend.

Further details and application forms from Dr M L Hooper, Institute of Genetics, Church Street, Glasgow G11 5JS, Scotland. *Closing date for applictions: 30 November, 1979.*

CONFERENCES

THE NEW YORK ACADEMY OF SCIENCES

Conference on

GENETIC VARIATION OF VIRUSES

Barbizon-Plaza Hotel,
New York City
November 28-30, 1979

The Conference is co-chaired by Pet Palese (Mount Sinai School of Medicin New York) and Bernard Roizm (University of Chicago). Important topi to be discussed include the genet mechanisms responsible for selectio variability and stability of viruses in natur whether or not all viruses exhibit gene variation, and whether some genes with viruses may vary more than others.

The Conference will also examine t implications of genetic variation different viral systems. Evidence accumulating that specific genes determi the host range, virulence, and grow characteristic of viruses. Equal significant is the fact that genetic variatic may be used in the epidemiologic identification of strains. The Conferen will bring together virologists active engaged in basic research and tho involved in the development of antivir vaccines. For further information write t

Conference Director, The New Yo Academy of Sciences, 2 East 63rd Stree New York, NY 10021. W342(C)

GRANTS and SCHOLARSHIPS

THE ROYAL SOCIETY

SCIENTIFIC PUBLICATIONS GRANT

Applications for grants from the seco allotment of the Scientific Publicatio Grant for 1979 should be made not lat than 22 October 1979 on forms obtaina from the Executive Secretary, The Roy Society, 6 Carlton House Terrac London, SW1Y 5AG. The grant is for t assistance of scientific publications in t United Kingdom, particularly, but n exclusively, those of scientific societies a institutions.

Applications are receivable only fro societies and institutions in the Unit Kingdom and individuals of Briti nationality. 3079(H)

LECTURES

LEUKAEMIA RESEARCH FUND

H-2 Thy-1 Ia IgD Monoclonal Antibodies

FOR

- **FLUORESCENCE STAINING**
- **CELL SEPARATIONS**
- **CYTOTOXIC DEPLETIONS**
- **GENETIC TYPING**

HIGHLY SPECIFIC REAGENTS DETECTING MOUSE CELL-SURFACE ANTIGENS

	H-2	**Ia**		**IgD**		**Thy-1**
Specificity Detected	H-2K^k	Ia^k(17)	Ia^k(2)	Ig5a	Ig5b	Thy-1.2
Monoclonal Heavy Chain Isotype	γ_{2a}	γ_{2b}	γ_{2b}	γ_{2a}	γ_1	γ_{2b}
Clone Designation	11-4*	11-5*	11-3*	10-4*	11-6*	30-H12†
Species Derivation	Mouse	Mouse	Mouse	Mouse	Mouse	Rat
Directly Cytotoxic	Yes	Yes	Yes	Yes	No	Yes

28 DEC 1979

AVAILABILITY
FOR FLUORESCENCE STAINING

- HAPTENATED, PURIFIED MONOCLONAL ANTIBODIES (Arsanilate or Biotin Conjugates)
- FLUORESCEIN AND RHODAMINE-LABELED SECOND-STEP REAGENTS (Avidin, Anti-Arsanilate)

FOR GENERAL RESEARCH USES

- PURIFIED MONOCLONAL ANTIBODIES
- ASCITES FLUID (Anti Thy-1.2)

QUALITY CONTROL

- FACS (FLUORESCENCE ACTIVATED CELL SORTER) ANALYSIS
- 2-D GEL ELECTROPHORESIS
- MICROCYTOTOXICITY

NOT FOR HUMAN DIAGNOSTIC USE.

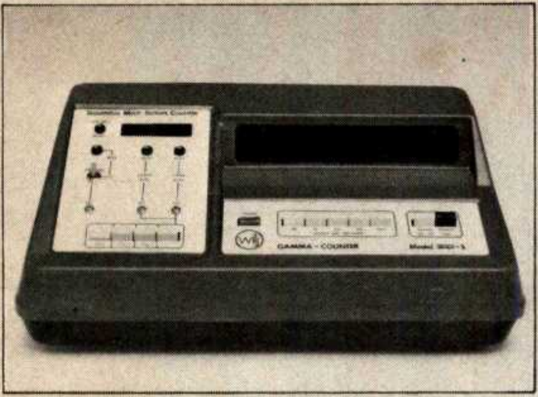
The British family Wilj announce two talented new members



Gamma Counter 2001-S

- 50mm Crystal, 50mm shielding
- Multiple-channel facilities (SMIC)
- Additional user variable window
- Digital display directly in KeV
- Accepts alternative external counting heads
- Incorporates our unique easy to calibrate system

RIA Data-Processor 2701

- Easy to use — it asks you the questions
- Dual-channel
- Choice of curve fits: Polylinear, Logit/log & Spline
- Statistical checks

These two new additions increase Wilj's long lead on other lower-cost RIA equipment. This combination can count and process **double-isotope kits** in one simple operation.
Higher energy isotopes can be counted with the larger crystal and increased shielding.

Data-processing is no problem with Wilj peripheral options. Teletypes, paper tape, data-logger and the Hewlett-Packard 9815A programmable calculator and software can all be accommodated.

Whichever combination you choose, all Wilj products come complete with an unconditional 2 year guarantee. (U.K. Only)

SYSTEM 2001

PROVEN RELIABILITY, VALUE AND PERFORMANCE

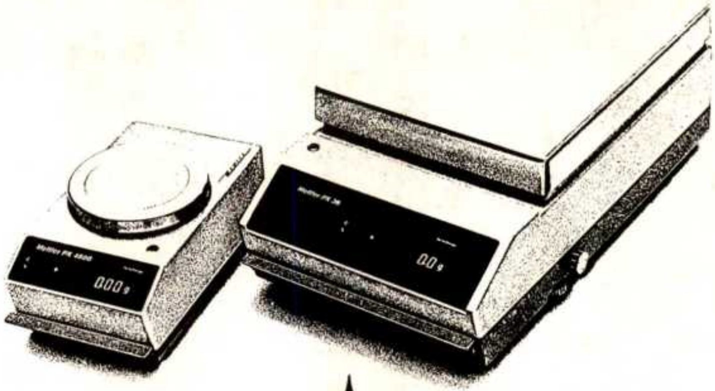
Balances from Mettler:



A more versatile weighing technology

- New high-speed readout
- Dynamic integration time extension
- Self-calibration
- Data output standard
- And, of course, the time-tested single control bar

More versatile weighing

- Can be used under both good and poor conditions
- Quality assurance
- Parts/piece counting
- Animal weighings
- Can be connected to EDP systems

Weighing is now much more versatile.

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258,**1 (1975) and **264,**v, 11 Nov. (1976).

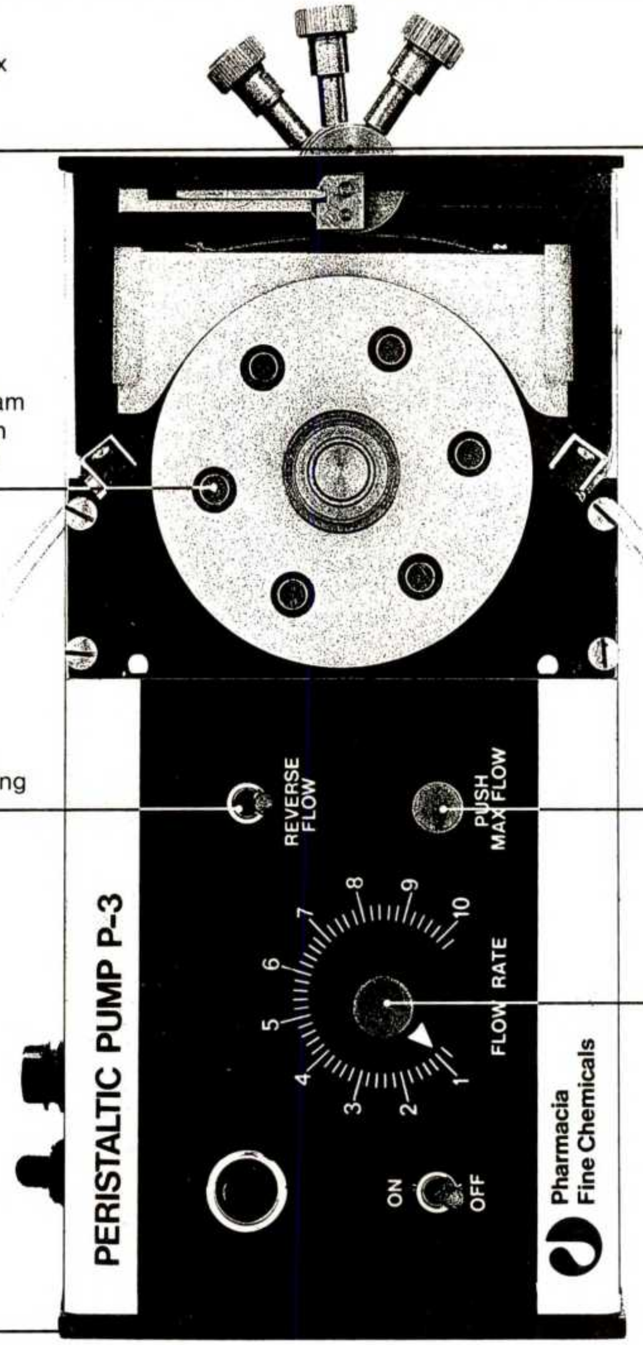
The Pump

Check what it can do for you!



Linear, concave or convex gradient formation by three channels

Different flow rates to three columns by three channels

Undisturbed chromatogram due to minimum pulsation by six gear driven rollers

Flow versatility with three different tube sizes

Can save column repacking

Saves time when clearing bubbles from system by overriding pre-set flow rate

Reliable flow rate (0.6–400 ml/hr) due to electronic load and temperature compensation

Saves bench space. Only 11x11 cm

The Pharmacia Peristaltic Pump P-3 is your ideal general-purpose laboratory pump for column chromatography, density gradient formation and many other biochemical techniques where reliable liquid flows are required.

Its versatility gives you convenience and saves your time and money. Let this pump work for you in your lab. Ask for detailed information today.

Another sort of braindrain

The steady drift of young scientists away from many rural and even urban areas in the UK must be stopped.

One of the easier things for the delegates to UNCSTD, the United Nations Conference on Science and Technology, to decide upon in Vienna recently was that the flow of qualified personnel away from developing countries is one of the most serious obstacles to development. It was equally easy to enjoin developing countries to create the appropriate work environment, and the developed countries to go steady on their recruiting from the Third World. Whether these fine words make an iota of difference to the brain drain is, of course, another matter. And, apparently for political reasons, one type of brain drain — from one developing country to another — was discreetly not mentioned in the Vienna documents, although it is growing in size and could potentially do considerable damage by the syphoning off from one country to another of people with skills of particular relevance to development. Not all the brain drain problems exist in the Third World, however. First World countries can suffer from less publicised but equally disturbing movements of qualified people, and inadequate attention is paid to this problem.

In Britain, as in many other countries, every young person with at least a passing interest in science will certainly be able to study the rudiments of physics, chemistry and biology. In every school with any pretensions to academic quality at all, those who wish to pursue this interest in more detail will be able to concentrate on the sciences, which may additionally include subjects such as geology and psychology, up to the level of university or polytechnic entrance. At this stage, however, for reasons of convenience, the process of concentration starts, and the next three years have to be spent in one of the hundred or so cities in which facilities for higher education exist.

What happens upon graduation? Most but not all of those with scientific qualifications will gravitate towards the academic and teaching world, towards the civil service or towards science-based industry. As far as school-teachers are concerned, opportunities exist, of course, anywhere within the UK. But this is far from true for most other forms of employment. The curious reader might take a list of scientific jobs available outside school-teaching and plot their location on a map. The chances are quite strong that a circle of radius 100 km centred on London will encompass at least 60 per cent of all the vacancies. The chances are equally strong that the number of openings north of the Trent will be less than 20 per cent of the total available.

Scientific jobs in Wales, Scotland and Northern Ireland are particularly rare, as are those in relatively rural parts of the country. But a matter of considerable interest is that jobs in many large cities which achieved their prosperity through industry in the nineteenth century are also relatively uncommon. South-East England is by far the most fertile field for scientific employment in the UK, as it is for many other types of white-collar employment.

Does this matter? In some ways it is a good thing if it ensures a critical mass of scientific expertise capable of sustaining the UK's position in the face of international competition. But whilst there are benefits to be derived from concentration, there are also serious disadvantages. If bright young scientists from large areas of the UK cannot find satisfactory employment in their home area but have to migrate to better-endowed areas, there comes a time when the school-teachers who have been diligently educating these students only to see them all disappear begin to lose heart, and science is listlessly or even badly taught. There comes a time when the scientific awareness of whole regions of the country declines because there are inadequate numbers of scientists around to sustain it. There eventually comes a time when good potential scientists are lost in large numbers.

Centres of excellence are undoubtedly desirable in some academic disciplines, and it would be folly to disperse, say, particle physicists to all corners of the country. But much science-based industry, and many civil-service establishments do not really need to be within close reach of London to be effective; their presence in regions at present less highly populated with scientists might even be of more value than being within an hour or two of the capital city.

There is no obvious time to grasp this problem; the brain drain is slow and makes few headlines. But unless there is careful study of the problem soon, followed by corrective action, the pace of the migration will continue to grow to the detriment of large areas of the country. □

0028-0836/79/370089-01$01.00

US expected to exempt most recombinant DNA experiments from federal regulation

Eighty-five per cent of US recombinant DNA experiments will be exempted from controls, if the recommendations of a national committee are accepted. **David Dickson** reports

A large proportion of current experiments using recombinant DNA techniques is expected to become exempt from federal regulations covering such research, following a recommendation which a national advisory committee agreed last week to make to the director of the National Institutes of Health.

In a split decision, the NIH's recombinant DNA Advisory Committee agreed that all experiments using the 'disabled' K12 strain of the bacterium *Escherichia coli* be exempted from the guidelines, except for those which are known to present a particular type of hazard.

The decision has been taken after pressure from scientists, many of whom have argued that the results of recent research fail to support earlier speculations over the hazards of recombinant DNA research. Critics, however, still argue that such a decision is premature, and that there is inadequate knowledge of the risks involved to justify taking such a significant step at this stage.

In its recommendation, the RAC suggests that the experiments exempted from the guidelines should still be carried out under P1 containment conditions, the lowest of four levels of physical containment established in the guidelines which were first published by the NIH in 1976. It also recommends that the experiments should be notified to local institutional biohazard committees, which all institutions carrying out recombinant DNA research on federal funds are required to set up.

However under the committee's recommendations, which are expected to be accepted with little alteration by Dr Donald Fredrickson, director of NIH, there will be no need to obtain prior approval for the experiments from the local committee. Nor will it be necessary to inform the NIH's own Office of Recombinant DNA Activities (ORDA), as all research workers are required to do at present.

Members of the advisory committee voted by ten votes to four, with one abstention, in favour of the exemptions. In general, the scientific members of the committee, many of whom are actively involved in recombinant DNA research or related fields, voted in favour of the exemptions — while those appointed as 'public interest' representatives on the committee voted against them.

During the debate on the proposal, it was said that about 85% of current recombinant DNA experiments were conducted using the *E. coli* K12 strain. The proposed exemptions would not apply to experiments currently prohibited under the guidelines, such as those involving the transfer of genetic material from known toxins, or to experiments involving more than 10 litres of culture — for which special permission is required.

Some members of the committee argued that no decision should taken before the committee had had time to examine the implications of the risk assessment scheme which has been developed by Dr Sidney Brenner of the Medical Research Council laboratory in Cambridge, England. This approach is now being used as a basis for decision-making by Britain's Genetic Manipulation Advisory Group. However other committee members argued that Dr Brenner's concerns were adequately covered by the NIH guidelines. And it was also decided that it was not necessary to wait until Dr Brenner could appear personally before the committee before recommending exemption for the *E. coli* K12 experiments.

During the committee's two-day meeting in Bethesda, approval was given to a set of procedures which have been drawn up by the director of NIH under which private companies can voluntarily register their experiments with ORDA.

Dr Fredrickson told the committee that he was confident that commercially sensitive information could be adequately protected, a factor that had previously made companies reluctant to divulge details of their proposed experiments. He also said that before leaving the Department of Health, Education and Welfare, ex-secretary Mr Joseph Califano had indicated that he was opposed to new legislation covering the private sector.

In a subsequent closed session, the committee gave its approval to large-scale experiments involving more than ten litres of culture submitted by the pharmaceutical company Eli Lilly and the west coast research company Genentech. The two companies are currently collaborating on efforts to produce sufficient quantities of human insulin to begin clinical trials.

The committee also agreed on a set of procedures, based on proposals of a small working group, on how it should conduct its business. Against the advice of the NIH's legal counsel, Mr Richard Riseberg, the committee decided that members having a 'personal stake' in the outcome of a particular line of research should not necessarily be excluded from discussions realted to that research.

Mr Riseberg informed the committee that it might be contravening federal law if, as an advisory committee, members took part in such discussions. Some committee members, however, pointed to the difficulty of determining what 'personal stake' meant in the context of scientific research — and the committee decided to strike out the provision. ☐

US to harmonise remote sensing

The United States has agreed to initiate efforts to "harmonise and rationalise" international activities in the field of remote sensing — the mapping of natural resources from satellites. Such efforts should, according to the US, have two main goals: ensuring the compatibility between the remote sensing systems now being developed by different industrialised countries, and stimulating the full use of remote sensing data by the developing countries.

The decision to take this initiative was announced during the first week of the United Nations Conference on Science and Technology for Development held in Vienna last month, by Father Theodore Hesburgh, head of the US delegation to UNCSTD. Addressing the plenary session of the conference, Father Hesburgh said that the US proposed bringing together the operators of remote sensing satellites, as well as the users, to develop an international system.

"We believe that satellites should be operated so that all can have easy access to the data and so that information can be collected without unnecessary duplication and for maximum mutual benefit", Father Hesburgh said.

"The objective is to ensure developing countries improve their access to information for the use and management of forests, rangelands, water supplies, soil preservation, and the indentifiction of new mineral and water resources."

The Administration has been under pressure from Congress for some time to decide what steps to take following the experience gained with the series of Landsat experimental satellites. Landsat A was launched in 1972, and operated successfully for five years, and its successor Landsat B was launched in 1976. The last of four satellites, Landsat D, is due to be launched in 1981.

Despite the exceptionally high quality of the Landsat images, analysis of them had had mixed success. In some areas, such as the survey of water or mineral resources,

0028-0836/79/370090-02$01.00

the satellites have produced a large yield of high quality information. In others, initial goals have proved to be over-optimistic. In particular, it has proved far more difficult than predicted to use satellites for assessing agricultural yields — for example because of problems in distinguishing between different types of crops — and more research is now being done in this area.

Enough information has been gained so far, however, to convince the US that remote sensing can provide useful information to developing countries in fields from water resource engineering (such as building dams or irrigation systems) to mineral prospecting. The US Agency for International Development (AID) has already carried out research projects and training in more than 30 countries, demonstrating how Landsat data can be used by local planners and policy-makers.

Speaking in Vienna last week after Father Hesburgh's address, Mr Tom Pickering, director of the State Department's Bureau of Oceans and the Environment, said that in announcing its new initiative, the US had two main goals, both of which were intended to held developing countries make better use of remote sensing data.

The first goal is to bring together the various countries now planning their own satellite systems to ensure the maximum possible complementarity and compatibility. The aim, for example, would be to ensure not only the minimum of overlap and duplication, but also that wherever possible a developing country receiving station could use the same equipment for receiving data from different satellites.

The second goal is to bring together, possibly on a regional basis, those who intended to use satellite data to obtain information about their own resources, and how these might best be managed. "Our hope is that through discussion with users we can define together the sort of data that can be most effective in answering their needs, and in discovering about their own territories the type of things that they would like to discover," Mr Pickering said.

The Administration's decision was welcomed by Senator Adlai Stevenson Jr, chairman of the Senate's Science and Space Subcommittee, who has long been a critic of the current Administration's lack of plans for an operational Earth-monitoring satellite system, advocating this as one of the most important areas in which US technology can help developing countries.

Describing the wide potential applications of remote sensing, Mr Stevenson said that the US "was concerned that these technologies will follow many national courses and that, if some cooperative steps are not taken soon, it may be too late to at least develop complementary technologies. By complementary we mean not only the physical systems, but also in their operation, so that satellites can be used in a way that avoid redundancies and maximises knowledge of the resources of the world."

Backing up the proposal made in Father Hesburgh's speech, AID mounted an exhibition in Vienna demonstrating the type of data that can be derived from Landsat and other satellites, and the way in which it might be used. The exhibition was to have been entitled "remote sensing: an appropriate technology for economic development" — until advocates in AID of a less capital-intensive approach to Third World needs objected, and the word "appropriate" was dropped from the title.

David Dickson

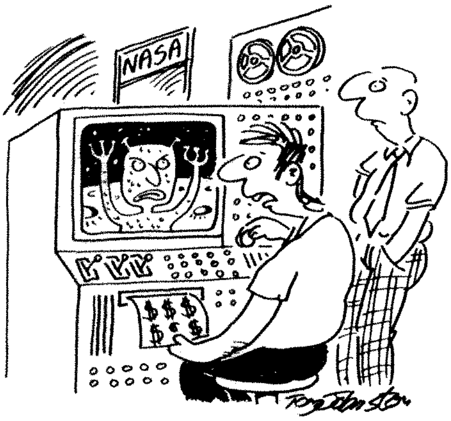
Interference with data from Titan

Vital data on the surface temperature of Saturn's giant moon Titan may have been lost as the result of radio interference during the transmission of the data from the Pioneer 11 spacecraft to the National Aeronautics and Space Administration's Ames Research Center in California last week. In place NASA has a series of dollar signs, printed by the computer receiving the data as an indication that it was unintelligible.

At first it was thought that all the relevant data, which came from readings made by an infrared radiometer aboard the spacecraft and would provide important clues about the planet's atmosphere, had been lost. However subsequent investigation showed that the data had been received — but in a highly garbled form. NASA scientists are now trying to unscramble what they can; they are confident that some of the information can be retrieved, but remain uncertain about its quality.

"The data was ratty, make no mistake about that. But it's there, and it may all be there, all 20 minutes of it, ground up in some scrambled data that was fouled in the communication link between Madrid (one of the three receiving stations for Pioneer transmissions) and California," mission chief scientist Dr John Wolfe said last Thursday.

Late last week, the precise cause of the radio interference was still uncertain. Initially it was stated that the interference had been caused by a Soviet satellite in Earth orbit, Cosmos 1124, which NASA officials had forgotton to ask Soviet scientists to switch off during the period in which the Pioneer data was being transmitted.



"It's the Titans! They say if we want to take pictures we can pay for them!"

On Wednesday, the space agency issued a statement identifying the satellite as the cause of the problem. The statement continued: "NASA officials indicate that they have no doubt that the Soviets would have avoided the conflict on Monday, if they had been asked. However the impact of the potential interference was not recognised in time to make an additional request to the Soviets."

By the next day, however, NASA had changed its mind about the cause of the interference. Rather than the Soviet satellite, they now blamed the combined effect of a solar storm and low quality land transmissions between Spain and California — an explanation which had been put forward at the very beginning, but rejected when the Cosmos satellite's involvement had become known. □

Bulgaria plans to save energy

During the next Five Year Plan (1981-1985), all Bulgarian "energy consuming enterprises" will become subscribers to *Promishlena Energetika* (Industrial Energy), an organisation established this summer and described by Energy Minister Nikola Todoriev as "a scientific production combine". The main purpose of *Promishlena Energetika* is the saving of all forms of energy across the economy; its activities range from the reconstruction and modernisation of existing inatallations to an extensive research and development programme.

What precise form this research would take, the Minister did not specify. He was addressing a symposium on "Fuel and Energy saving and new energy resources" held in conjunction with the annual Plovdiv trade fair. Scientific seminars at the Fair were introduced some ten years ago, and, according to Penko Penkov, Chairman of the Bulgarian Chamber of Commerce, are the response of the organisers to the information explosion.

"Rapid technical progress makes us organise sceintific and technical symposia", said Penkov, "in order to give experts from many countries a chance to keep up with the latest developments". This year, there were no less than twelve day or half-day seminars on subjects ranging from ergonomics, geodesy, and the stimulation of scientific creativity to textile and leather technology and the bacteriology of yoghourt. The three day energy symposium, however, with its massive foreign participation and the full

0028-0836/79/370091-02$01.00

panoply of simultaneous translation, undoubtedly dominated the scientific events.

Foreign participation, indeed, was the major feature of the symposium. Apart from the Minister's speech, there were four Bulgarian contributions (on geothermal and solar power, hydrogen fuel and secondary power sources). Otherwise, with the exception of one Polish contribution, all papers were contributed by Western experts, ranging from nuclear to hydraulic power sources, and from general policy to specific devices.

This willingness to borrow Western achievements is nothing new to Bulgaria. One exhibit at Plovdiv — that of the *Progress* organisation, established last year to help bridge the gap from research and development to large scale implementation- carried as its motto a quotation from Mstyslav Keldysh, late President of the Soviet Academy of Sciences, that it is not the nation which makes the first breakthrough who enjoys the benefits of a discovery but the one which implements it properly.

In 1976, said the Minister, when Bulgarian energy policy was revamped with the establishment of the National Energy Complex, Bulgaria had reached the position of one of the most developed nations in the world "in the energy sector at least" having increased specific consumption per head from 9% below world average in 1953 to twice the world average.

The new policy took a three-fold approach, stressing increased exploitation of local resources (mainly lignite), an expansion of nuclear generating capacity (which will reach 35% of the total generating capacity by 1990, with subsequent introduction of nuclear district heating for Greater Sofia) and a major programme of energy-saving.

In spite of massive efforts at economy by industry and domestic consumers alike, these "passive measures" are not considered to be sufficient. Modernisation of existing plants, training of personnel to get the best use from their apparatus, and even the introduction of automated control systems for energy-intensive processes will all peak by the mid 1980s — leaving further gaps to be filled. These, stressed the Minister, can only be satisfied by new technologies.

Some of these will, of course, be of Bulgarian origin. Todoriev mentioned a new Bulgarian scheme, already in operation at the Maritsa-Istok-3 power station, which allows lignite to be burned without predrying — giving an overall fuel saving of some 5%. Others, including solar energy, the use of the geothermal waters of the Rhodope mountains, and the pressing problem of secondary energy resources, may well, if one judges from the Plovdiv seminar, rely considerably — at least in the early stages, — on foreign know-how.

Vera Rich

Pugwash calls for new efforts to control chemical weapons

The Pugwash Workshop on Chemical Warfare has joined impatient voices calling for progress in negotiations on a chemical weapons (CW) disarmament treaty. At a meeting in Stockholm recently, the Workshop urged that the current situation in the negotiations be re-appraised for the Biological Weapons Convention Review Conference, scheduled for 1980. The Review Conference is charged with assessing progress in CW disarmament as well. Most members of the Pugwash group also advocated the reopening of multilateral negotiations on a CW treaty, for there is a major weakness in the Biological Weapons Convention is that it allows research into new biological agents for 'defence'.

Since 1976, the US and the USSR have been having secret talks about chemical weapons disarmament — a subject earlier discussed at the multilateral Geneva Disarmament Conference. But the superpowers' bilateral talks have made no progress. They have instead taken the wind out of the Geneva negotiations, and many of the delegates to the Disarmament Conference have expressed themselves impatient with the stagnation. For example, the leader of the Swedish delegation, Mrs Inga Thorsson, tried recently to move things along when she suggested that the conference should begin its own CW negotiations in parallel with the superpowers. The Pugwash group urged the reopening of multilateral negotiations irrespective of the state of the bilateral talks.

A CW capability consists of different elements: laboratories for research and development, facilities where the weapons are made, and facilities where they are stockpiled. Any treaty aiming at CW disarmament must deal with all these different elements. The Workshop considered them in turn, asking for each whether it would be better to destroy it or convert it to civilian use, and how such measures could be verified.

Pugwash, a private affiliation of scientists interested in disarmament questions, is not an official government body, but it provides a useful arena for its members from east and west to test ideas and atmospheres. The temperature of the official negotiations can be said to be above freezing simply because the Pugwash group is still functioning. At this meeting, the 30 participants produced nothing dramatic; but some of them (who preferred not to be named) were prepared to point to parts of its report with cautious optimism.

It was, for example, said to be a hopeful sign that the report contains a list — agreed by both sides — of six infrastructural recommendations for the verification of the destruction of declared stockpiles. Perhaps the most interesting of these points are that whatever international body is established to verify the destruction, it should have an independent technical capability, and that continuous presence of monitoring personnel at the destruction site would be necessary. The latter does not mean that the USSR, after years of refusing on-site inspection, has decided to allow them after all; but the report reflects agreement on more details of on-site inspection, and in this sense it may indicate a slight softening of the Soviet attitude.

What did emerge, however, from a visit the group made to the Swedish pharmaceuticals factory KabiVitrum AB, is that that on-site inspection need not jeopardise commercial secrets. In recent years, the Workshop has visited commercial chemical factories in West Germany and the United States, and a US Army chemical/munitions disposal facility.

Next year, the group plans to visit a site in East Germany. The visits have enabled the group to explore verification questions which could arise under a CW convention. Invasion of chemical factories by inspectors has long been opposed on grounds of commercial privacy; but as the Pugwash group visits more facilities in more countries, its experience suggests that opposition to some forms of international control of the chemical industry rests on shaky ground.

It was also reported that the discussion on confidence-building measures (CBM's) provoked more reaction than usual. CBM's are steps the sides can take to increase mutual trust: voluntary exchanges of technical and methodological information on chemical research and development related to CW problems, for example. The more trust there is between the sides, the fewer formal verification procedures are needed. Various CBM's have been discussed by previous meetings of the Workshop, but this one produced an additional concept for increasing mutual trust: 'obligatory CBM's under a CW convention'. The group felt that it could be useful to treat certain sorts of treaty provisions as CBM's: provisions, for example, which might be valuable but difficult to verify under a treaty. The discussion on CBM's was laced with controversy about which measures would be best to adopt; and at least one participant was surprised that both sides agreed to mention them favourably in the report.

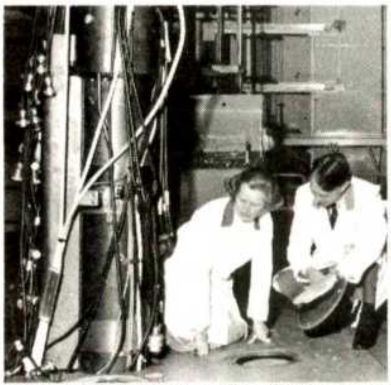
news in brief

Gluons at DESY: Results from the PETRA electron-positron storage rings at DESY, Hamburg, are being taken as confirmation of the existence of the 'gluon'. This massless particle, is according to 'quantum chromodynamics', the mediator of the strong force between quarks: it is the 'glue' which keeps quarks bound into particles such as the proton, neutron, and other hadrons. Quantum chromodynamics (QCD) has been developed in analogy to quantum electrodynamics (QED), the immensely successful relativistic quantum theory of electromagnetism. The gluon in QCD plays the role of the photon in QED. However its discovery may not foretell the 'technological revolution' seen by the *International Herald Tribune* on 30 August: like the quark, it has proved impossible to separate from the hadrons of which it forms a part. The experimental evidence for it, now gathered by several teams at DESY, is a set of events showing the production of particles correlated into three 'jets' or streams — a signature of the decay of a gluon (see *News and Views*, page 104). Early evidence for the gluon was presented by one of the teams at CERN, Geneva, in June; this has been corroborated by data presented at Fermilab, Chicago, by a collaboration headed by Samuel C.C. Ting.



Britain's nuclear future: Britain's Prime Minister, Margaret Thatcher (right), last week reaffirmed her intention to press forward with a nuclear programme for Britain. After starting-up the new fuel reprocessing plant in Dounreay, Northern Scotland, she said that personally she would like to see the go-ahead for a full sized commercial demonstration fast reactor possibly at Dounreay, but there would be a public inquiry first. She expected this decision to be made within two years, and then another eight to ten years to pass before the first commercial station was built.

Britain will also soon have its first pressurised water reactor. The Central Electricity Generating Board has been looking at four PWR designs and is expected to recommend the US Westinghouse design. Sizewell in Suffolk, Dungeness in Kent and Hinkley Point in Somerset are all possible sites currently being investigated by the CEGB.

Meanwhile Friends of the Earth with other anti-nuclear bodies have been discussing ways of improving their effectiveness in the anti-nuclear campaign. According to Czech Conroy from Friends of the Earth, they want a "better coordination of our opposition to nuclear power".

ICRP lung models out: UK National Radiological Protection Board studies published in the Board's latest annual research and development report have shown that industrially produced radioactive dusts do not necessarily behave as predicted by the International Commission on Radiological Protection models. Very small particles of plutonium-239 dioxide, about 0.001 microns in diameter, have been found to be soluble in blood and move rapidly through the body, meaning the radiation dosage to the liver and bone could be up to ten times greater than estimated by the ICRP models. Normally only 0.1% of industrially produced plutonim dust is soluble, but if the plutonium aerosol is produced in conjunction with sodium, for example in fast breeders where sodium is used as a coolant, up to 50% of the aerosol is composed of these small, soluble particles. However, the NRPB studies have also shown that the amount of plutonium entering the blood and deposited in extrapulmonary tissues following inhalation of actinide dusts over 1 micron in diameter, have been overestimated by a factor of ten by the ICRP.

Scientists attack Carter's approval of new missile sytem: The Federation of American Scientists has strongly criticised President Carter's decision, announced at the end of last week, to proceed with the deployment of a new generation of intercontinental ballistic missiles, the MX. After several years of studying alternative proposals for the design of the new system, the President has selected one in which 200 missiles will be deployed in underground shelters, mounted on lorries which can move them between alternative launch sites sufficiently fast to avoid a Soviet missile attack.

The whole deployment programme is expected to cost 32 billion dollars. In its statement, the FAS claimed that the MX "is not just a mistake but a disaster". The federation also voiced fears that the deployment of MX missiles would not only lead to escalation of the arms race, but would also render the Strategic Arms Limitations Treaty untenable, and might result in the abrogation of the anti-ballistic missile treaty. The statement questions the strategic value of the MX — and predicts that it will never be built.

Hungary and UK revise science and technology agreement: Hungary and the United Kingdom have drawn up a new programme for long-term cooperation in applied science and technology. In practical terms, this simply continues existing cooperation projects with one or two additions such as metallurgy and communications engineering. Formally, however, it represents a compromise between the Hungarian and British approaches to such exchanges.

The original UK/Hungarian agreement for cooperation in science and technology was signed in 1967 under the umbrella of the Intergovernmental Joint Commission, which covers all aspects of economic relations between the two countries. In 1977, however, the Hungarians wanted to take scientific cooperation out of the sphere of the Joint Commission, and draw up a special agreement. Exchange agreements between Western and Comecon countries have tended to link trade and scientific exchange probably because scientific cooperation is handled on the British side by the Department of Trade, and on the Hungarian side by a mixed panel representing the relevant ministries. A special agreement could have rationalised this structure, but this very difference made it impracticable to give science and technology an agreement of its own. It does, however, now have its programme formulated in a separate document.

Argentina accused of responsibility for deaths and torture of scientists: The government of Argentina bears "ultimate responsibility" for permitting the disappearances, tortures and deaths of many Argentine scientists, according to a statement issued in Washington last week by the National Academy of Sciences and the American Association for the Advancement of Science. It says that the Argentine government has been "totally unresponsive" to repeated inquiries made into the fates of many scientists, engineers and students who have disappeared since the military government seized power in March 1976.

Such inquiries had been made by both individuals and groups within the scientific community, including the American Physical Society, the American Psychological Association and the Massachusetts Institute of Technology. "The problem is not solved by the government's assertion that it knows nothing of the fate of these 'disappeared' citizens or that they are victims of terrorists," the statement says.

It adds that Argentina cannot have a respected place in the world of international science until the respect for human rights of all citizens permits honest inquiry and freedom of discussion without fear for personal safety.

Why France has had no public nuclear debate

France has not had the public debates on science and technology of other western nations. **Pierre Papon**, of the Ecole Superieure de Physique et Chimie Industrielles, Paris, outlines why.

ALTHOUGH the past five years have seen considerable — and sometimes violent — political debate in many western countries over the objectives and implications of technological and scientific advances, notably nuclear power and genetic manipulation, France has been remarkably free from public discussion or dissent. The French have traditionally left decisions on science policy to the government in power, and nowhere is this more evident than in the nuclear power programme. Despite its wide socio-political implications, the main decisions on nuclear power have been taken solely by the government, along with a governmental agency — the Commisariat à l'Energie Atomique (CEA) — and the public utility, Electricité de France.

Political decisions have been taken on at least three important occasions in the history of the French nuclear programme. First there was General de Gaulle's decision, based on advice from R. Dauty and the physicist F. Joliot, to found the CEA in October 1945. After the scientific and technological infrastructures had been built up, the parliamentary vote in July 1952 for the first five-year plan for the CEA was a new decisive step. This plan included the building of thermal reactors producing plutonium, which were to form the basis of the future military nuclear programme, launched under the initiative of the then Chief Administrator of the CEA, P. Guillaumat. Although it began slowly, the military nuclear programme accelerated after 1958, and the government eventually decided to shift from gas-cooled reactors to pressurised water reactors. This major decision in 1969 was endorsed five years later when the Messmer government embarked on a new nuclear programme.

Under this plan, the EDF was authorised to build and operate a nuclear capacity representing 38GW of installed power, supplying 50% of elelctricity demand in 1985. This will include 900MW PWR nuclear reactors, and more powerful 1300MW reactors built by Framatome under licence from Westinghourse. The programme will be completed by breeders, the first commercial prototype being the 1200MW Superphenix reactor which is being built at Creys-Malville, Isere, by an industrial society in cooperation with Italy and West Germany. The French nuclear programme is thus extremely important, despite delays and high costs.

Scientists' reactions

After the government had decided to launch this large nuclear programme in 1975, a group of some 400 scientists reacted against the magnitude of the programme and the lack of public debate on nuclear problems. As the 'Groupement de Scientifiques pour l'Information sur l'Energic Nucleaire' (GSIEN) these scientists, mainly physicists, publish regular newsletters giving the main scientific and technical data relavant to the nuclear debate and expounding the socio-political implications. Since it has political contacts and an honest audience, this group has performed a useful task in disseminating information. The union of workers of the CEA, affiliated with the CFDT, has regularly warned the authorities of the technical and social risks of the nuclear programme; recently for example, they drew attention to safety problems related to working conditions at the fuel reprocessing plant in La Hague. The action of the physicists in promoting a public debate on nuclear problems, however, has no equivalent in other fields: a group of biologists, among them a few connected with Pasteur Institute, met with little success when they tried to initiate a public debate on recombinant DNA research a few years ago.

The Three Mile Island accident has recently put increased emphasis on the question of nuclear reactor safety. The French Physical Society (Societe Francaise de Physique, SFP) the professional society of physicists, seized this opportunity for opening a debate on the problems of reactor safety at its biennial general meeting in Toulouse in the last week of June. The discussion now conducted by a panel of physicists, which included two members of the CEA (M. Tanguy, Head of the Protection and Nuclear Safety Institute and M. Droulers, Director of the Department of Evaluation of Safety of Reactors) and was chaired by B. Dreyfus, vice-president of the society. The members of the CEA were questioned on the Harrisburg accident and on its implications for the French nuclear programme, especially for the safety of the PWR reactors. The debate focused mainly on technical and scientific problems, such as the behaviour of the primary coolant in biphasic conditions, the crucial problem of instrumentation inside the containment vessel, the reliability of data available to the operators, and the probability of major accidents like those occurring after a thermal shock or a core melting. Questions were also asked about the technical competence of reactor operators and their ability to cope with a major accident.

The participants also tackled the question of whether outside scientists should be involved in planning and executing nuclear safety research programmes. The concensus was in favour, but no precise agreement was reached on how such participation could be achieved. The CEA physicists did display confidence in the PWR reactors, although they admitted that some events which occurred at Three Mile Island had not been taken into account in considering accident risks, including the formation of a large hydrogen bubble, and they also conceded that more attention should be paid to the behaviour of the secondary system and to the instrumentation of the primary coolant.

Although this meeting is not a landmark in the nuclear debate, it is important in that it constitutes the first attempt by the Societé Francaise de Physique to open a discussion among its members on an important element of the nuclear debate. Other discussions, on the fuel cycle and on various reactor systems (including breeders), are planned.

Government traditions

The reasons for the lack of previous public debates on major technological issues like nuclear power lie largely in the traditions of French government. Until the second world war, successive governments held science and technology to be low priorities in national policy, although they kept a tight hold on some industrial areas like energy supply. With the post-war move into high technology, state intervention took place in research areas important to France's technological independence, beginning with nuclear power in 1945, and extending to aerospace and computers in the 1960s.

Because of their national strategic importance, decisions in these fields have been felt to be the responsibility of governmental decree rather than laws passed by parliament.

In the nuclear power field, there have been a few debates in parliament, and no general legislation has been passed. For example, although the breeder Superphenix is partly financed through the budget, the decision to build such a reactor was taken by a decree in May 1977 without a vote in parliament. France does not have any procedure of public inquiries to allow the assessment of major technololgical programmes with the participation of independent experts, as in the Windscale inquiry in the UK. These two facts have combined to weaken the possibility of a serious political debate.

Parliament's role is a rather weak one, since it has no standing committee on science and technology as such. The 'Commission des Finances' deals with major problems of science and technology in the National Assembly, but these two committees do not have sufficient technical means to investigate complex technical problems. In April 1979 a law creating a

0028-0836/79/370094-02$01.00

special permanent comittee for the assessment of major technical proposals was passed by the National Assembly — against the opposition of the Minister for Industry A. Giraud (a former head of the CEA), who declared it unconstitutional; it is now before the Senate.

After the Harrisburg accident a special investigation committee was set up by the National Assembly and its four members went to the US. In their preliminary report, published on 27 June, the deputies insisted on the necessity of informing the public about nuclear safety, and they insisted that the government should publish the intervention plans prepared in the case of an accident. This report, although useful, falls short of the full-scale assessment needed of the safety problems involved in the nuclear programme.

In France it is also traditional that the government resists efforts to make public all the factors on which its decisions are based. In the energy domain the weight of the powerful public organisations EDF and CEA is not balanced by other institutions challenging their conclusions.

The high-ranking Civil Service considers that it has, as the ultimate political power in the country, the right to intervene in high technology sectors and to control the decision-making process. Information also comes under its power, and it is reluctant to abandon even some of this to parliament, which has indeed rarely shown a real interest in the problems of science and technology. The creation of a special inter-ministerial committee, chaired by Mrs Simone Veil, former Minister of Health, which will disseminate information on nuclear energy is a step in the right direction. Unfortunately this committee has devoted most of its time, since its creation more than a year ago, to simply informing itself.

Another element of the problem is that the French government usually trusts what L. Kowarski called 'les competences instituées' (representatives of public institutions, business, large organisations, and so on). It is typical that the government asked a panel of members of the Academie des Sciences to comment on the official report of the Harrisburg accident; and, given the reluctance of the Assembly to engage in controversial matters, one can estimate how useful their opinion will be.

Competent experts who may have views and opinions which conflict with those of the government are not involved in the decision-making process. To be fair one must add that the scientific community, with few exceptions, has rather fought shy of all problems related to the implementation of science and technology. It has tended to expound its views on the general situation of research, and retreated from questions with social or political overtones. One may hope that the severity of the social and economic crisis will now oblige the government and the scientific community to enter a dialogue with public opinion. ☐

French scientists oppose CNRS reforms

A STORM is building up within the French scientific community around the government's proposed reform of the country's highly centralised research organisation, the Centre National de la Recherche Scientifique (CNRS). In August nearly 200 scientists, engineers and technicians demonstrated against the plan — and this in a month when nearly all the French go on holiday. In addition, a lengthy polemic has been opened in the national press on the subject while the main trade unions involved in the CNRS are promising further activity this month.

The reforms, proposed by Giscard d'Estaing's government, have two basic themes: a structural reorganisation of the CNRS itself and a change in the direction and control of research goals. The remit of the CNRS runs from pure mathematics through physics, chemistry, biology to linguistics, musicology, history and philosophy. Thus any change is bound to have a major impact. It was originally set up to develop the career of "research scientist" independent of university teaching and as a profession in its own right. Currently its budget is FF3,500 million (more than £35 million); it employs 8,300 research scientists (more than one half the national total) and 13,000 engineers, technicians and clerical staff, all its employees enjoying the rank of civil servants.

The CNRS is presently governed by a rather Byzantine array of interlocking committees and directorships. The original plan envisaged a system with most committees at the top having both elected and appointed members. Thus, for example, the National Committee for Scientific Research, which is supposed to oversee part of the budget and the performance of the various laboratories, is composed of 41 subcommittees, each covering a seperate discipline, and each with 26 members — 15 elected by the staff and 11 named by the government.

In fact another more hiearchial structure has grown up within the CNRS. It consists of seven directors, each in charge of a commission which oversees the work of all labs in its area. The directors report to the director-general of the CNRS, currently M Robert Chabbal. There are no elected members in this chain which has now established *de facto* control of finances and the review of the work of the centre. In the words of M Chabbal, "the French like pyramidal structures."

The first part of the proposed reforms will "regularise" this unofficial structure, giving it permanent form and official control. Although the National Committee would continue to exist it would have only advisory powers, while real power will lie with the appointed directors and their commissions. The main thrust of this part of the reform then is to introduce a more "streamlined" though less "democratic" management with more autonomy for the different fields of research.

The three unions, who represent a substantial number of the scientists, engineers and technicians at the CNRS, and whose members took part in the August demonstration, are calling for militant action against the reform. Meanwhile a petition circulating among researchers at the CNRS had gathered 230 signatures within the first fortnight of its launch.

The second aspect concerns the structure of research itself. The traditional "vertical" division of the CNRS by discipline has for some time been supplemented by "horizontal" intra- or inter-disciplinary projects. Examples of these are the 30 or so GRECO (Groupements de Recherches Coordinees) agreements which reflect national level single discipline studies and the more than 40 GIS (Groupements d'Interets Scientifiques) or cross-disciplinary studies, for example, the CNRS/University of Montpelier/local authorities solar energy project. The reform calls for an increased emphasis on these "horizontal" structures with more input and responsibility being given to the CNRS's partners, particularly industry.

What is feared is that the real aim of this reform is to dismantle the centralised structure of the CNRS with forcible merging of laboratories, "nationalisation" of the work force and the placing of the resulting smaller and more vulnerable pieces under private industry. In particular, the social and human sciences are scarcely visible in the new scheme while the more "physical" disciplines will be heavily weighted towards rapid and easy profitability.

On the one hand, the director-general M Chabal, stresses the advantages of more fluid discipline boundaries and increased ease of formation of new research areas. On the other, opposition scientists and unions warn of private industry's control of research goals and the loss of autonomy of the scientific community. Whether a major confrontation will actually develop depends largely on the government's tactics. In France, it is not uncommon for proposed legislation to be postponed even after its announcement or for bills, once passed, to be left unenforced.

If the reforms go ahead one result may be the opening up of debate on the nature of research itself, which is beginning to be discussed in the socialist trade union CFDT. Are scientists, private industry and the State the only possible judges of the value and direction of research? What about the people themselves and their participation in research decision?

Nuclear India

This week a law comes into operation in the US which will have the effect of foreclosing nuclear fuel supplies to India. **Anil Agarwal** here considers India's nuclear future

India's underground nuclear test in Rajasthan: Desai condemned it

THERE is no more emotive tissue in the field of science and technology in India today than atomic energy. Since the 1974 nuclear test at Pokhran, the Indian Government has been under enormous pressure from western nuclear powers — in particular US and UK — to sign the Non-Proliferation Treaty (NPT). India has always insisted that the Pokhran test was entirely intended for peaceful purposes and that the NPT is an extremely discriminatory document, which does nothing to curtail the proliferation of nuclear weapons in the existing nuclear weapon states.

While all Indian governments had regularly denied any interest in nuclear weapons, Prime Minister Morarji Desai turned the making of any nuclear bomb by India into an even stronger moral issue than had his predecessors. In characteristic style, Mr Desai told western reporters after the Commonwealth meeting in London in 1977: "I'll give it to you in writing that we will not manufacture nuclear weapons. Even if the whole world arms itself with the atom we will not do so". Recently, when the news broke that Pakistan was involved in building a uranium enrichment plant, there were demands from several members of parliament that India should make its own nuclear weapons. But Mr Desai again stated: "I am neither prepared for the manufacture of the atom bomb nor will I sanction funds for it".

When Mr Desai was Prime Minister, he closed Indian options for peaceful nuclear explosions, which all earlier Prime Ministers had studiously kept open. He even criticised the Pokhran explosion, which had been proclaimed a major national achievement during Mrs Gandhi's term in office — a view shared by most of the country's intelligentsia.

Mr Desai told parliament that Mrs Gandhi had conducted the Pokhran explosion for political rather than scientific gains. Mr Desai immediately faced a barrage of criticism. "Your unilateral declaration abjuring nuclear explosions even for peaceful purposes and ambiguous and contradictory statements on nuclear policy have raised profound misgivings about the future scope and objective of our nuclear programme," wrote an angry Mr Y.B. Chavan, in a letter to Desai in late 1978. Mr Chavan, a veteran Indian politician, who was then leader of the Opposition and is now Deputy Prime Minister in Mr Charan Singh's government, added: "we were very surprised and disturbed by your extraordinary statement on the Pokhran explosion. You may have had your own reasons for making it, but in the process you chose to pronounce on the technical aspects of the explosion, denigrating our scientists and engineers who were involved in the project. It has been recognised by experts all over the world that technically the Pokhran explosion was a fine job.

Mr Desai replied reiterating his stand. "It is quite clear to me" he wrote, "that you do not know the details and the lessons that were learnt. Technically there is no doubt that it was a good effort but compared to achievements elsewhere it was a very small effort." Moreover, the explosion had created international problems for India. He explained that the "explosion is always held against us as a preparation for warlike use of atomic energy and you know very well how it is being exploited by our neighbours so that they can blackmail foreign governments into assisting them in acquiring that capability themselves."

With foreign nuclear powers, Mr Desai took a straightforward moral position. He agreed to throw open all the nuclear reactors in India to international inspection and accept fullscale safeguards, but only on the condition that the nuclear powers themselves sign a comprehensive nuclear test ban treaty, agree to reduce their own stockpile and open their own reactors to international inspection. Mr Desai informed Mr Chavan in his letter: "In my private discussions both with President Brezhnev and President Carter I have even made it clear that unless the safeguards are extended to military reactors they cannot insist on our having them."

When Mr James Callaghan, the then UK Prime Minister, followed President Carter to negotiate with Mr Desai, just a week after the latter's visit to New Delhi in early 1978, Mr Desai once again refused to sign the NPT. But he agreed to open India's reactors to international inspection once there was a basic international agreement amongst UK, USSR and USA for a comprehensive test ban treaty. By leaving out France and, more important, China, which is the immediate nuclear power on India's borders, even several western observers accepted that Mr Desai had made a significant concession. Earlier this year, President Carter publicly admitted that he found it difficult to argue with Mr Desai's moral position.

However, within India itself Mr Desai was strongly criticised by almost all leading newspapers and politicians for his soft and yielding stand over NPT. Many commentators said that he had set India on a slow march towards acceptance of international safeguards. A leading columnist of the Times of India, wrote: "Mr Desai is a man of high principles. He is a conscientious objector to nuclear weapons under any circumstance. It is to his credit that he would rather resign than do anything against his conscience. Even so, must he forswear, on behalf of India, nuclear weapons for all time to come, regardless of the circumstances? As a senior member of (former Prime Minister) Mr Nehru's cabinet, he must know that it was with the full concurrence of the then Parliament that Panditji had declared himself to be opposed to going in for nuclear weapons. But he had taken care to add that though he hoped that future parliaments would agree with his view, he would not bind them down. This is a more rational approach than a blanket rejection of nuclear weapons. And the least that the Prime Minister ought to do is to seek the present parliament's endorsement for his stand."

When the Indian government agreed to a US proposal to set up an independent committee of nuclear experts to study, as Dr Jospeh Nye of the US put it, "the question of what safeguards options were available for states which were not members of the NPT", there was immediate suspicion amongst politicians and press commentators that the country may have walked into a trap. The reasons for setting up the committee have never been sufficiently explained but it seems US diplomats had claimed that the committee's deliberations would help to soften public opinion in the US against the supply of nuclear fuel to India.

0028-0836/79/370096-02$01.00

However, until the western powers made up their minds about a comprehensive test ban treaty, Mr Desai's government took careful steps to ensure that India does not have to accept fullscale safeguards on its reactors. The constant irritant in Indo-US nuclear relations is the Tarapur Atomic Power Station. The US government is obliged under a 1963 agreement to supply enriched uranium fuel for the entire lifetime of the station. But under a new law, it now has to stop supplying nuclear fuel to any country which has not signed the NPT by March 1980. The law does not even exempt sales to those countries with whom the US had previous agreements. Naturally, the Indian government has protested against it.

Over the past few years there have been extraordinarily long delays in supplying nuclear fuel to India. The last consignment of fuel arrived in March, 1979, about 13 months after the Indian government had applied for it. At that time, the US government had not even presented to the Nuclear Regulatory Commission, which permits sales of nuclear fuel, another Indian application sent in September 1978 for yet another outstanding consignment. Many Indians felt that the March consignment too had been sanctioned only because Indian leaders had started discussions with the USSR over the supply of enriched uranium. But because of these delays, the Nuclear Fuel Complex at Hyderabad, which manufacturers fuel elements, had to close down its workshops. The new US law forbids the government from considering further applications for nuclear fuel sales after 10 September.

The US government had believed that the new law would force the Indian government to see its viewpoint. But Mr Desai, strongly supported by Indian public opinion, informed the US government that refusal to supply enriched uranium for the Tarapur reactors would be treated as a unilateral abrogation of the previous agreement. India would have no further obligations to observe the bilateral safeguards which are imposed on the reactors at the moment and would be free to reprocess the spent fuel from them. Under the existing agreement, the US has the right to buy back the fuel.

Plans to use plutonium

No decision about the spent fuel has yet been taken and it is being stored in reservoirs which are now full. The storage capacity is to be expanded, but as soon as the legal position about the fuel is clear, India would like to extract plutonium from it at its waste processing plant at Tarapur. The Indian Atomic Energy Commission claims to have developed a new fuel consisting of natural uranium enriched with plutonium to replace the enriched uranium fuel supplied to the US.

Scientists at the Bhabha Atomic Research Centre have indigenously designed and built a plutonium-fuelled small experimental reactor so India has experience of working with plutonium fuels. With fuel supplies that have already been agreed upon, the Tarapur station should be able to generate power until 1982. That should give the Atomic Energy Commission time to fabricate the new fuel.

The option of using mixed plutonium and uranium oxide fuels could embarrass the US government which has always been against the use of plutonium in thermal reactors, and has even tried to prevent European countries from using it. Its diplomatic offensive against India might well produce a situation it has otherwise tried to prevent. Once plutonium starts being used in thermal reactors, the total amount in the world could jump from 25 tonnes to well over a thousand tonnes, making it almost impossible to police its use. The fuel supply for Tarapur is, therefore, supposed to be an open issue. The US President may well decide to continue to supply nuclear fuel to India to stop this precedent from taking place. There is, of course, the even more important worry that Indo-US relations would take a nose-dive.

The Desai government had also taken steps to prevent fresh safeguards being applied to the Rajasthan Atomic Power Station (RAPS). After the Canadian government had unilaterally broken its agreement with India in 1976 to supply heavy water for the second unit of RAPS, Mrs Gandhi's government had started negotiations with the USSR. The Russians, however, insisted on even stronger multiple-point safeguards than the Canadians. An agreement with the USSR was concluded in 1977, soon after Mr Desai's government took office. Under it the IAEA has the right to inspect any other nuclear system in which any material generated in the Rajasthan station is used. India has an experimental fast breeder reactor under construction at Kalpakkam, where its second major nuclear research centre is being developed. RAPS-II is now reported to be ready but the Russian heavy water has not yet been used. Until it is, the safeguards agreement does not come into operation. It is possible that India will keep the RAPS-II idle until it can manufacture its own heavy water.

Apart from the Tarapur station, all the Indian stations are heavy water-moderated, natural uranium-fuelled, CANDU-type reactors. India manufactures its own natural uranium fuel, but remains critically short in its heavy water requirements, and is thus dependent on foreign sources. Apart from a small heavy-water production unit in operation at Nangal, there are four large plants under construction. The first is being built by Indian engineers at Kota. Designs for this plant were obtained from Canada but even the Canadians have found difficulties with similar plants. The Kota plant too has been plagued with difficulties and delays, and has thus seriously undermined India's plans to gain expertise in heavy water production. It is expected to begin operation in 1980.

Three other plants are being built at Baroda, Talcher and Tuticorin by French and West German companies. All are suffering delay. The Baroda plant started trial runs several years ago but a chemical explosion seriously damaged it and it is now being repaired. The Talcher plant was delayed when two massive steel towers which had been shipped from Europe got mysteriously swept away at sea. Both the Baroda and Talcher plants are now expected to start operating by the end of this year. The Tuticorin plant has been undergoing trial runs but it has been plagued with problems in the ammonia plant of the fertiliser factory with which it is linked. Once these plants begin operating, they should be able to supply the heavy water needed for the nuclear reactors under construction.

The Indian nuclear power programme itself has been lagging behind the schedules projected in the early 1970s because of serious management and construction problems. Nuclear stations at Madras and Narora, which are under construction, are expected to take more than ten years to build, and their costs have escalated considerably. This has led to resistance from both the Ministry of Energy and the Planning Commission to sanction funds for more nuclear reactors. This situation existed under Mrs Gandhi's government but Mr Desai told parliament that the government wanted first to cope with the atomic power plants already taken up before thinking of setting up new ones. A fifth plant has been under consideration for several years — either in the State of Gujarat or as an extension to the existing Tarapur Station. Mr H.N.Sethna, Chairman of the Atomic Energy Commission, claimed a few weeks ago that its location may be decided by December.

The slow progress of the nuclear programme has certainly left young engineers working with the Atomic Energy Commission in a very uncomfortable situation as far as their careers are concerned. The plans formulated in the early 1970s had envisaged that one nuclear power station would be sanctioned every year. But now many senior engineers have remained stuck in their old positions for over a decade as they have no new sites to move to, and their junior colleagues have remained in their junior positions. It is the same story, for different reasons as in many developed nations. But the under-employment of engineering talent — some 30,000 working in India atomic energy establishments — is a much more severe problem in a developing country. The unfortunate thing is that as long as external foreign pressures exist, no government in India will find it easy to evaluate seriously the role of nuclear energy in its future energy development programmes. □

Biased reporting of East European science

Sir, — There should be little doubt nowadays that science needs extensive, systematic and friendly international ties for its own progress, for positive service to humanity and for contributions that such ties make toward safeguarding peace and avoiding the world-wide devastation which advanced science and technology have guaranteed to be inherent in a war between major powers. Even arms limitation and, hopefully, arms reduction are not only general human concerns but also professional issues affecting the direction of science and the question as to whether its major efforts will be oriented toward destruction or toward human welfare.

The near catastrophe this year at the nuclear plant at Three Mile Island, Pennsylvania, has underscored dangers which could arise even in the absence of war, and leads one to be grateful for the existence, since 1973, of the US-USSR Joint Committee on Co-operation in the Peaceful Uses of Atomic Energy. Its fifth meeting (Washington, April 1978) gave prominent attention to work on 'Light-Water Reactor Safety' — the type of reactor used in the US — and to plans for intensifying work on this topic, whose importance the whole world now appreciates.

A sense of responsibility to science, to peace, to mankind would require the encouragement of such co-operation and its substantial expansion.

It is, therefore, very sad to observe *Nature*'s failure to exercise this responsibility, and its degeneration into a propaganda sheet for those anxious to whip up an hysterical ill-will against East European science. In what has assumed the dimensions of a campaign, it seems to be doing what it can to encourage those seeking to destroy co-operation, or even contact, between the scientific communities of Eastern Europe and those of the US and its allies. News articles do not conceal their bias and editorialising. For example, a news report (7 September 1978, page 3) under the headline "Boycott of Soviet contacts is for individuals, says NAS [National Academy of Sciences]" stated early on "This reaction would appear to substantiate the case for boycott, a case most ably put by Valentin Turchin". The rest of this 'report' is similarly tendentious and argumentative. Incidentally, the Turchin letter and similar ones were published, not in the space normally reserved for letters, but more prominently, in larger type and with conspicuous headlines.

The author of that article is a regular contributor to *Nature*, Vera Rich. Her numerous articles are chiefly propagandistic, lacking in analysis, highly selective, crowded with sneers and sarcasm, ill-mannered and disruptive, and contemptuous of Soviet science. They do not offer the reader any well-rounded picture of East European scientific life and developments, to say nothing of the fruits of international scientific cooperation.

Underlying all the sarcasm and the jibes is the unwarranted assumption that Soviet science and the science of other socialist countries is very much the junior partner in any cooperation. Occasionally this is stated explicitly, and such views given more or less unchallenged publicity. One anonymous letter (14 December 1978) asserts that in 1965 the US and the USSR had about the same number of scientists, but that the former did one-third of world science, the latter only one-sixth. Leaving aside measurement problems, one might ask why *Nature* didn't point out that through its money the US has fortified its science establishment by visiting upon other countries a 'brain drain' which has caused even its closest allies to complain and which has damaged developing countries, while the USSR has relied almost exclusively on its own population. As a perhaps atypical example, it might be noted that the School of Mathematics of the Institute of Advanced Study at Princeton has normally been staffed at the professorial level by a majority of great imports.

In any case, Soviet and other socialist scientists are no 'junior partners' in international science, no matter how *Nature* portrays them.

But the blame for this destructive campaign cannot be placed on Vera Rich's pen alone. *Nature*, itself, has weapons in its arsenal. Some day a doctoral dissertation will analyse headlines, positioning, type-sizes, linguistic techniques and much else, to the amusement of the author and the embarrassment of the editor.

Without awaiting such refinements, I am concerned about such things as an *anonymous* full-page article (13 October 1977, page 548) by what *Nature* calls "a correspondent with some experience of East European countries, . . . [who] returned [from the GDR] with these impressions". No explanation is given as to why this correspondent was permitted a cloak of anonymity to shelter an ungracious guest's snide barrage. *Nature*'s editorial introduction to this piece declared "Scientific exchanges with the German Democratic Republic (GDR) are rare, and our knowledge of the state of its science is consequently sparse". It neglected to mention that NATO countries refused until recently to recognise the GDR, excluded it from the UN, and were unwilling to negotiate exchanges earlier, or even to permit GDR citizens to visit under their own passports. Every effort was made by NATO to isolate the GDR. For years the International Mathematical Union allowed its FRG-affiliate to act for both German States.

In passing, let me mention that I have made three brief scientific visits to the GDR (in 1965, 1972 and 1978), and that the colleagues I met there were well-trained, skillful, enthusiastic scientific workers who were far from conveying the "frustration and pessimism" which your anonymous correspondent claimed to be the prevailing mood.

I hope that the editors will not await future doctoral candidates to analyse the myriad ways in which *Nature* demeans itself today. *Nature* is an important voice in the international scientific community. Its editors should take cognizance of the grave responsibility this implies, and should bestir themselves to establish some objectivity, balance and reason into its activities impinging on the crucial field of scientific co-operation between the countries of Eastern Europe and other major scientific centres.

Yours faithfully,

Lee Lorch

York University, Ontario, Canada.

Uranium use in fast reactors

Sir — R.D. Smith in his letter on fast reactor safety (23 August, page 630) says, "remember the fast reactor will produce about 60 times more energy than a thermal reactor for the same quantity of uranium".

I thought this particular piece of nulcear nonsense had been scotched for good. It might be true in 200 years time, but certainly is not for any period which is significant for our present situation. When challenged by Leslie Granger and David Merrick (*Energy Policy* December 1976, and *Nature* 16 December 1976, pages 596-8) Bart Cutts, Head of Technical Services at UKAEA eventually (*Energy Policy* September 1977) presented a "notional programme of electrical installation". One is justified in assuming that it was the best case he could produce, especially as he found it necessary to assume a very low growth rate for electrical energy of 2½% p.a. Even so the ratio of utilisation of uranium for a programme based on the maximum development of FBRs and one based only on thermal reactors was 1.1 by 2000 and only 1.7 by 2020, compared with this absurd figure of 60 times which might be achieved by 2200.

For the sort of increases in electricity production that used to be achieved and were projected at least until 2000, i.e. anything over 5½% p.a., Granger and Merrick have shown that the ratio cannot exceed 1½ times as long as this rate of increase continues. The reason is simply that, as Walter Marshall has said, fast breeder reactors are really breeder fast reactors, or perhaps better, slow breeder fast reactors. To achieve even the rate of increase, modest by historical standards, of 5½% p.a. it is necessary to build large number of thermal reactors to provide most of the increase and furnish plutonium to start up the FBR series. These gradually breed more plutonium, and the process goes asymptotically to the use of 1½% of the uranium instead of the 1% for thermal reactors. The higher the annual increase is above 5½%, the more slowly is this figure of 1.5 approached, never to reach any higher unless the annual increase comes below 5½%. As we have seen, even for an annual increase as low as 2½% p.a. it only goes to 1.7 by 2020.

On a related point, in order to reach a stage when further supplies of uranium are no longer required, the rate must be below 3% p.a. Above that the need to import uranium never ceases.

It is to be hoped that R.D. Smith's corrections of Norman Dombey (other than the misprint) are rather more relevant than his reference to the improved utilisation of uranium.

Yours faithfully,

J.W. Jeffery

Birbeck College, University of London, UK.

Defending science and rationality

Sir, — I have just read your editorial (23 August, page 619), on 'Science, nonsense and responsibility'. I do so with that slightly sour amusement always induced by the spectacle of Satan denouncing sin. Having read your editorial and review columns for many years, I find your pose as a defender of science and rationality decidedly unconvincing. However, if you should now switch to opposing the major as well as the trivial superstitious movements of our time, no one would be more pleased than I.

Yours faithfully,

M. Hammerton

University of Newcastle upon Tyne, UK

Structure and force generation in muscle

from John M. Squire

THE sliding filament model of muscular contraction, proposed 25 years ago, is now generally accepted to account for the shortening in muscle; the thick myosin filaments interdigitate with the thin actin filaments and when these filaments slide past each other the muscle changes length. However, within this basic scheme, relatively little is known about the structural details of the force-producing mechanism which causes the filaments to slide. The thick filaments contain projections (the myosin heads or crossbridges) which can split ATP, which can bind to the neighbouring actin filaments and which have an ATP turnover rate that is increased by actin binding. Tension is related to ATP usage, so the crossbridges are clearly implicated in force generation. It is commonly assumed that the crossbridges in an activated muscle first attach to actin and then change their attachment configuration through a number of mechanical steps during which force is generated. The crossbridges subsequently detach from actin and reset themselves ready for a further attachment cycle. Although the kinetics of the biochemical steps in the actomyosin ATPase cycle are fairly well defined (see Lymn *A. Rev. Biophys. Bioeng.* **8**,145; 1979) the details of the corresponding changes in structure are still relatively uncertain and much effort is being devoted by structuralists to defining the sequence of mechanical steps involved in force generation.

One of the most useful experimental probes available to the structuralist is the X-ray diffraction technique, since, unlike electron microscopy, it can be applied to muscle which is living and, if required, actively producing tension. Of the various regions of the resulting X-ray diffraction patterns which can be studied, one of the most informative is the equator. This is the region which provides information about the density profile of the muscle when viewed down the muscle axis. Figure 1 shows schematically the appearance of such a view in the A-band of vertebrate skeletal muscle. Here the myosin filaments (M) form a hexagonal array with the actin filaments (A) at the trigonal points of the lattice. The principal diffracting planes in this lattice are the $10\bar{1}$ and $11\bar{2}$ planes as indicated in Fig. 1. The actin filaments lie between the myosin filaments when the assembly is viewed along the $10\bar{1}$ planes, but are in line with the myosin filaments in a view along the $11\bar{2}$ planes. This means that if there is a movement of mass from near the myosin filaments to near the actin filaments when a muscle is activated, the effects on the $10\bar{1}$ and $11\bar{2}$ X-ray reflections will be different. More mass at the actin filaments will tend to smooth out the density profile in a view down the $10\bar{1}$ planes (that is, the $10\bar{1}$ reflection will get weaker), whereas it will tend to enhance the density profile in the $11\bar{2}$ view (that is, the $11\bar{2}$ reflection will get stronger). In fact it was shown very clearly by Huxley (*J. molec. Biol.* **37**, 507; 1968) and later by Haselgrove and Huxley (*J. molec. Biol.* **77**, 549; 1973) that the intensity ratio ($I_{10\bar{1}}/I_{11\bar{2}}$) of the $10\bar{1}$ and $11\bar{2}$ reflections changed from about 2.5 for muscles at rest, to slightly less than 1 for muscles generating tension and to about 0.25 for muscles put into rigor (all at rest length). The rigor state is known to be one in which a large number of crossbridges are attached to the actin filaments and these observations were taken to mean that fewer crossbridge attachments occur when a muscle is generating tension than in rigor.

Unfortunately, although it is generally true that the more attached crossbridges there are the lower will be the ratio $I_{10\bar{1}}/I_{11\bar{2}}$, the attachment number is in theory only one of a number of factors which can affect this ratio. Lymn showed (*Biophys. J.* **21**, 93; 1978) that the configuration of the attached bridges also has a marked effect on this ratio. Lymn considered two attached states for the myosin heads, one with the long axis of the heads at about 45° to the thin filament axis (as in the rigor state) and one at about 90° to the thin filament axis. His modelling showed that a ratio $I_{10\bar{1}}/I_{11\bar{2}}$ of about, say, 0.5 could be due either to labelling by crossbridges in the 45° configuration of 40% of the actin monomers in the thin filaments or to 20% labelling by crossbridges in the 90° configuration. Since it is now thought that a number of attachment configurations might be involved in each crossbridge cycle in active muscle, it is clear that the intensity ratio of the equatorial reflections will not in general be a good indicator of the number of attached crossbridges. However, provided the distribution of crossbridges among the attachment states is constant, as may well occur in muscles which generate tension at a fixed length (isometric contractions), it is possible then that the equatorial intensity ratio might vary directly according to the number of attached crossbridges and therefore, on present thinking, to the level of isometric tension generated by the muscle. In a recent

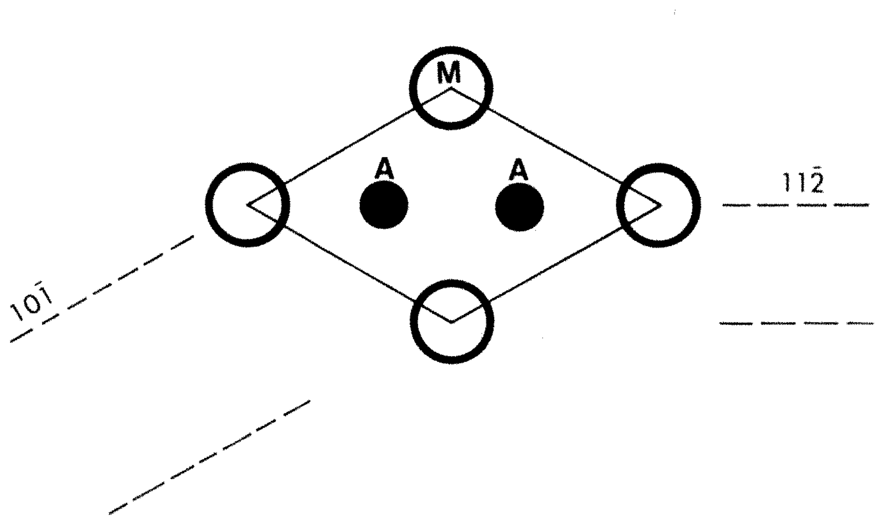

Fig. 1. Unit cell of the hexagonal array of filaments in the overlap region of the sarcomere in vertebrate skeletal muscle. M, myosin filaments; A, actin filaments. The directions of the $10\bar{1}$ and $11\bar{2}$ planes are indicated, in this view of the unit cell down the long axis of the muscle.

0028-0836/79/370099-02$01.00

paper, Yu, Hartt and Podolsky (*J. molec. Biol.* **132**, 53; 1979) have presented the results of an elegant series of X-ray diffraction experiments in which they have monitored the individual intensities (and the intensity ratio) of the $10\bar{1}$ and $11\bar{2}$ equatorial reflections from frog sartorius muscles producing different levels of isometric force. They found that the ratio $I_{11\bar{2}}/I_{10\bar{1}}$ (the reciprocal of the ratio discussed above) increased systematically with increasing force (with a slight upward curvature), while the individual intensities either decreased ($10\bar{1}$ reflection) or increased ($11\bar{2}$ reflection). The observed variations were said to agree well with theoretical curves calculated assuming two populations of crossbridges, attached and detached, and the attachment number increasing linearly with tension. Although this is clearly an oversimplification, it supports the general contention that more crossbridge attachment should be associated with greater tension generation. This result differs markedly from the previous observations of Podolsky *et al.*, (*Proc. natn. Acad. Sci. U.S.A.* **73**, 813; 1976) on muscles shortening at different speeds under a constant load. In this case it might be expected that both the attachment number and the distribution of attached states would vary with shortening speed, but Podolsky *et al.* found that the equatorial intensity ratio varied very little. It must be concluded either that the current ideas are wrong or that both the distribution and number of the attached bridges change together in such a way that the effect of one is virtually cancelled by that of the other.

One feature of the new results of Yu *et al.* on isometric contractions, not immediately explained by their modelling, was the observation that the intensity of the 101 reflection dropped rapidly from its resting value even at relatively small tensions and then reduced more slowly as tension increased. Yu *et. al.* attributed this to some disorder in the filament lattice accompanying the low level of crossbridge attachment, but an alternative addition to the simple two state model is the addition of a third activation step before crossbridge attachment to actin can occur (Squire *A. Rev. Biophys. Bioeng.* **4**, 137; 1975). Such an activation step is suggested by X-ray diffraction results from muscles stretched so that no filament overlap occurs (Huxley *Cold Spring Harbor Symp. quant. Biol.* **37**, 361; 1973; Haselgrove *J. molec. Biol.* **92**, 113; 1975). Here evidence was obtained for changes in thick filament structure on activation of the muscle even though no actin attachment was thought to be possible.

But the detailed interpretation of these results depends critically on the symmetry of the myosin filaments in vertebrate muscle. The crossbridges are thought to be arranged on a multi-stranded helix around the cylindrical myosin filament shaft. A 3-stranded model is now generally accepted but recent biochemical evidence (Pepe & Drucker *J. molec. Biol.* **130**, 379; 1979) suggests that there may be four strands. However, convincing structural evidence is required to settle the matter finally. Nor is this problem confined to vertebrate muscle. The thick filaments in insect flight muscle, larger in diameter than those in vertebrates, were initially thought to be 2-stranded and then 6-stranded. Now, Wray (*Nature* **277**, 37; **280**, 325; 1979) has suggested, largely on circumstantial evidence, that the number of strands of crossbridges on the insect thick filaments might really be four. It is crucial to our understanding of the mechanism of muscular contraction that the symmetries of these filaments be determined unambiguously. It would then be possible to interpret sensibly the wealth of X-ray diffraction data already obtained from muscles in a variety of states. The known biochemical kinetics of the actomyosin ATPase could then be related more realistically both to the number of attached crossbridges and to the different structural steps involved in the crossbridge cycle. □

Inverse lifetimes and the band structures of solids

from R.H. Williams

An accurate understanding of the behaviour of electrons in solids and the way that behaviour is related to the chemical composition and crystallographic structure is of considerable importance both fundamentally and technologically. The electrical resistivity of metals and insulators, and the behaviour of many solid state semiconductor devices, for example, depend on the detailed relationships between the energies and the momenta of electrons in those solids and accurate methods of probing the so-called 'band structures' have long been sought. Considerable progress has been achieved by studying such properties as the wavelength dependence of the optical absorption and reflectivity but during the past 10 years the technique of photoelectron spectroscopy has become one of the most promising and widely used. In the most commonly used form of the technique, electrons are emitted from the solid following irradiation by energetic photons and the energy distribution $N(E)$ of those electrons, which is clearly related to the occupied electron states, is measured. Quite recently the power of photoelectron spectroscopy has been vastly increased by the introduction of angle resolving techniques (see, for example, *Contemporary Physics*, **19**, 389; 1978) whereby a movable electron velocity analyser can probe $N(E)$ for electrons emitted in various directions. Assuming the momentum of the emitted electrons parallel to the surface to be conserved during the emission process then it becomes possible to establish this quantity inside the solid for the various electron states. Indeed for some materials, such as those which have a graphitic or layered structure, such measurements yield a good approximation of the full band structure which for the layered materials is largely two-dimensional in nature (see Larsen, Chiang & Smith *Phys. Rev. B* **15**, 3200; 1977). Interpretation of the experiments, however, may often be made complex due to the presence of the solid surface. The excited photoelectrons are strongly scattered by other electrons with the result that those which emerge without substantial loss of energy originate very close to the surface and may reflect the electronic structure of surface intrinsic or extrinsic (for example, due to absorbed gases) states. The short inelastic mean free path, or 'escape depth', of photoelectrons leads to a broadening of features in angle resolved photoelectron specroscopy and as pointed out by Pendry and Titterington (*Communications in Physics* **2**, 31; 1977) it should be possible from the peak widths in such experiments to determine not only the electron and hole lifetimes but also the electron mean free path and its variation with electron energy. This information is of considerable interest in the study of materials by electron spectroscopy.

Recently Eastman, Knapp, and Himpsel (*Phys. Rev. Lett.* **41**, 825; 1978; *Phys. Rev. B* **19**, 4952; 1979) and Thiry *et al.* (*Phys. Rev. Lett.* **43**, 82; 1979) have conducted inverse lifetime measurements of electrons and holes in copper single crystals using angle resolved photoelectron spectroscopy. At the same time the two groups have determined the electronic band structure of copper along well-specified crystallographic directions with unprecedented accuracy. Both groups used the power of angle-resolved photoemission and made use of the great advantages to be obtained by using synchrotron radiation as the light source (the synchrotron at the University of Wisconsin in the case of Eastman *et al.* and that at Orsay, France for Thiry *et al.*). Synchrotron radiation is a near ideal source for such studies as it is intense, highly polarised, and coupled to a suitable optical monochromator produces tunable photon energies over a large wavelength range. Both groups find that their spectra reflect occupied bulk electron states with momentum and energy being conserved in the emission process and by studying emission along a direction perpendicular to the crystal surface they were able to determine the full band structure along that direction. To map out the occupied electronic states it is necessary to have some knowledge of the states into

---

R.H. Williams is Reader in Physics at the New University of Ulster, Coleraine, UK.

028-0836/79/3700100-02$01.00

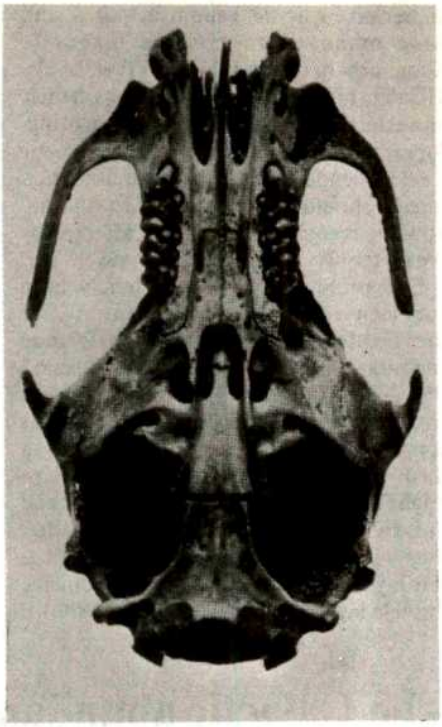
which the electrons are excited and Thiry *et al.* assume that excitation occurs into a free electron final state band. This procedure has previously been shown to give remarkably accurate results for the occupied states of some metals by Stohr *et al.* (*Phys. Rev. B* **17**, 587; 1978). Eastman's group makes use of the calculated electron states and both groups obtain very good agreement with theoretical predictions of the band structure of copper. Electron mean free paths determined from the experiments confirm the well known surface sensitivity of photoelectron spectroscopy particularly for excitation wavelengths below about 500 Å. Thiry *et al.* observe excited 3d hole lifetimes in copper which are in good agreement with the estimates of Pendry and Titterington, and further show the great importance of having a high angular resolution in the experiments.

These experiments again underline the power of angle-resolved photoemission coupled to a synchrotron radiation source as an accurate probe of electron states in solids. Studies similar to those described for copper, above, have also been conducted on nickel (Eastman, Himpsel & Knapp *Phys. Rev. Lett.* **40**, 1514; 1978) and the ferromagnetic exchange splitting accurately established. Coupled to other variations of the photoemission technique such as photoelectron diffraction (see *News and Views*, **279**, 755; 1979), which enable the locations of atoms near a solid surface to be established, an active and rewarding future in this area is certain, particularly as new dedicated synchrotron radiation sources such as the one at Daresbury in the United Kingdom become operational. These new methods will lead to a greater understanding of metals, alloys, semiconductors and insulators and will undoubtedly be important in probing areas such as surface reactions, oxidation of solids, and corrosion. □

The black rat in Britain

THE finding by archaeologists of remains of *Rattus rattus* in a filled-in Roman well in York in the north of England, suggests that the black rat was present in Britain several centuries earlier than had previously been supposed. The finds, which are discussed by James Rackham of the University of Durham in the latest issue of *Antiquity* (**53**, 112; 1979), lend support to the idea that epidemics of plague occurred in Britain well before the infamous Black Death of the Middle Ages, and may even have been common in Roman times.

Historians have assumed that the black rat — to be distinguished from its close relative the brown or Norway rat, *Rattus norvegicus* — was not introduced into Britain until the Norman period, when returning Crusader ships brought it from the Near East. The many contemporary records of 'plague' in Anglo-Saxon Britain in the 6th and 7th centuries AD have been either ignored or explained away as outbreaks of smallpox or other virulent diseases.



Black rat skull found in a Roman well in York.

There is no doubt that the high mortalities in the early centuries AD were often caused by a multitude of diseases, of which smallpox was certainly one. But it does not seem likely that Roman Britain would have completely escaped the plague epidemics that swept around the Mediterranean area and across Europe between the 1st and 6th centuries AD. The most serious of these pandemics — without doubt of bubonic plague — began in about AD 540 during Justinian's reign and spread from the Mediterranean up into central Gaul and Germany, and almost certainly would have reached the British Isles.

Plague usually spread from one coastal port to another because infected black rats would find their way on to and off ships. As there was extensive sea trading between Roman Britain and the rest of the Empire the introduction of rats into a British port could easily have happened. York was a thriving Roman administrative and trading centre. Like other large towns of the period, it was a port of call for supplies from many parts of Europe — indeed it is known to have had strong connections with Bordeaux and Rhineland. So it is not surprising that the black rat slipped into the town one day.

The rat remains recovered from the Roman well represent at least two individuals and include a well-preserved skull, a complete mandible with all its teeth, fragments of maxilla and premaxilla, and a cervical vertebra. The wall was timber-lined and was probably built in the late 2nd or early 3rd century and was then filled-in towards the end of the 4th century AD. During excavation careful checks were made to exclude the possibility that the rats had burrowed into the well after it had been sealed. This, and other evidence from Roman objects found in association with the rat remains and radiocarbon determinations suggest a 4th, or at the latest a 5th century date for the specimens.

These finds of the black rat in Roman Britain lend some support to John Wacher's controversial idea that plague led to the downfall of Romano-British towns in the 5th and 6th centuries AD at the time the Western Roman Empire was disintegrating. Wacher has suggested (*The Towns of Roman Britain*, Batsford 1974; *Roman Britain*, Dent 1978) that the depopulation of these towns was caused by epidemics striking an already threatened Romano-British culture. As economic decline set in, so the way was made easy for the conquering Anglo-Saxons and the start of the Dark Ages. S.B.

Quest for superfluid hydrogen

from P. V. E. McClintock

THE possibility of preparing monatomic hydrogen (H_1) at high densities seems to have come a stage closer with three papers published in recent issues of *Physical Review Letters*. Two separate research groups have simultaneously reported the first observations of magnetic resonance from H_1 held at liquid helium temperatures: Crampton, Greytak, Kleppner, Phillips, Smith and Weinrib of the Massachusetts Institute of Technology (*Phys. Rev. Lett.* **42**, 1039; 1979); and Hardy, Berlinsky and Whitehead of the University of British Columbia, Vancouver (*op. cit.*, 1042). On a slightly different tack, Guyer and Miller of the University of Massachusetts, Amherst, have calculated how H_1 may be expected to interact with a helium coating on the wall of its containing vessel (*op. cit.*, 1754).

The notion of monatomic hydrogen has been around for quite a long time. Hecht seems to have been the first to point out (*Physica* **25**, 1159; 1959) that H_1 at low temperatures and high densities might be expected to display quantum properties on a grand scale and, in particular, that it might undergo a superfluid transition rather like that of liquid ^{4}He. These possibilities rest on the observation that, although a pair of hydrogen atoms with oppositely directed electron spins attract each other and form a molecule of H_2, a pair of atoms with parallel electron spins (in a so-called triplet state) experience a repulsive interaction. This means that a gas of spin-aligned H_1 atoms could be cooled to very low temperatures, even at a high density, without ever condensing into a liquid, let alone solidifying, as do all other materials except helium (which stays liquid to absolute zero). The weak interaction forces between the atoms, coupled with the very low atomic mass, provide the ideal recipe for quantal behaviour: since the atomic mass is only a quarter that of ^{4}He, one may guess that the quantum properties of H_1 gas would be even more extreme than those of liquid helium.

Similar ideas can be applied to monatomic deuterim (D_1) and tritium (T_1), the heavier isotopes of hydrogen. Some interesting differences in their properties may be anticipated, however, because H_1 and T_1, each containing an even number of fundamental particles, are bosons, while D_1, with an odd number, is a fermion. Thus D_1 might perhaps be expected to behave rather like liquid ^{3}He, whereas H_1 and T_1 might each be expected to behave more in the manner of liquid ^{4}He. As gases, however, they would probably all have properties closer to those of ideal Fermi-Dirac and Bose-Einstein gases than the heliums. Such questions are of fundamental interest and importance for quantum mechanics and statistical mechanics, and this is a large part of the reason for the intense interest in seeing whether dense monatomic hydrogen can be made a reality on a macroscopic scale.

Although there has been a good deal of theoretical work on spin aligned hydrogen, with detailed predictions for many of its properties, relevant experiments have been somewhat thinner on the ground. The fundamental practical problem is, of course, to find a way of stabilising the H_1 gas against recombination to form H_2 molecules. The basic idea is to use a suitable container placed in an intense uniform magnetic field and held at a very low temperature. The field will induce a splitting in the ground state energy levels of the H_1 atom, depending on whether its electronic spin is pointing with or against the field; and it is hoped that the low temperature will ensure that the atom stays in the lowest level, that is, spin-aligned. It is believed that a field of 10 T and a temperautre of about 0.1 K might provide the necessary conditions for stable confinement of the H_1 gas. These conditions are realisable using existing cryogenic technology.

Before a full scale apparatus can be designed, however, it is necessary to obtain information about the properties of individual H_1 atoms at low temperatures and, in particular, about any mechanisms able to cause the spin flips which would rapidly lead to recombination to ordinary H_2. That is why the work reported from MIT and UBC is so important. Both groups have succeeded in conducting H_1 atoms down to experimental chambers immersed in liquid helium at 4.2 K and have managed to observe magnetic resonance between the hyperfine levels. This has now opened the way for further, more detailed, studies aimed at measuring, for example, the temperature and magnetic field dependences of the recombination rate. It should also be possible to find out how the recombination rate is affected by the material of the walls of the vessel.

One problem which had already been foreseen is that magnetic impurities inevitably present in the walls may encourage spin flips. A possible way round this difficulty would be to coat the walls with a layer of superfluid ^{4}He, which is completely non-magnetic. The question then arises as to whether the H_1 atoms might be able to enter the ^{4}He layer, and thus still be able to reach the walls; whether they will be trapped on the surface of the ^{4}He layer; or whether they will stay outside the ^{4}He layer altogether. Miller has shown (*Phys. Rev.* **B18**, 4730; 1978) that the H_1 is actually totally insoluble in liquid ^{4}He; Guyer and Miller now demonstrate that there will, in fact, be a shallow physiadsorbed state for H_1 just outside the ^{4}He layer, but that this state will not be heavily populated. They comment that ^{3}He impurities in the ^{4}He could give rise to difficulties since these, too, will congregate at the surface. This potential problem is easily circumvented however, because techniques have recently become available for the virtually complete removal of the 2 x 10^{-7} parts of ^{3}He found in commercial ^{4}He. So it looks very much as though a coating of isotopically pure superfluid ^{4}He will constitute an effective method for preventing wall-induced spin-flip processes.

Clearly, there is still a long way to go before superfluid hydrogen becomes a reality, but the present flourish of activity aimed in this general direction is most encouraging. □

The Galactic abundance gradient

from M.G. Edmunds

A CONSISTENT picture is at last beginning to emerge of the behaviour of the overall abundance of the elements, relative to hydrogen, as a function of position in our Galaxy. To a good approximation we can regard most elements heavier than helium as being produced in constant relative amounts during a single process — supernova nucleosynthesis — and the abundance of any one element is a fair indicator of the abundances of all the elements. There are of course a few exceptions, elements which are produced during quiescent stellar evolution such as nitrogen, but the majority are believed to come from supernovae. We can regard the Galaxy as a two-component system, made up of a disk of stars and gas, surrounded by a more-or-less spherical halo of old stars and globular star clusters. The pattern of the variation in abundance with distance from the Galactic centre in both disk and halo has become clearer with the publication of several papers over the past year.

K.A. James (*Astrophys. J. Suppl.* **39**, 135; 1979) has used narrow and wide band photometry to estimate metal abundance (anything heavier than helium) in a sample of giant stars and about 40 star clusters in the disk. Photometry can yield an abundance for a star because the strength of the absorption lines in the spectrum of the star's atmosphere is dependent on abundance, and the lines are not evenly distributed in wavelength. Thus a star with high abundances will emit less light in certain regions of its spectrum (particularly at short optical wavelengths), and more light in other regions, than will a metal-poor star. The differences are large enough to be detected by photometry of selected wavelength bands. The study of clusters is particularly useful because their distances can be estimated with reasonable accuracy, something that is very difficult to do for individual stars.

James finds there there is a distinct gradient of abundance decreasing outwards from the region of the Sun (10 kpc from the centre) to as far as he has measured at 14 kpc, although inwards towards the Galactic centre (from 10 kpc to 8 kpc) he claims to find little or no gradient. But his results are open to reinterpretation, and it may simply be that the classical notation for presenting abundances (as the logarithm of the quotient of the metal abundance relative to hydrogen in a star divided by the same thing for the Sun) may have obscured the actual trend. If James's data are replotted on a linear abundance scale, rather than a logarithmic one, then a simple straight line fits beautifully within the error bar in the plot of abundance against distance from the centre, both inside and outside the position of the Sun.

This therefore implies a simple linear abundance decrease in going from 8 to 14 kpc, a result which is in nice agreement with the indications of a linear abundance gradient in the interstellar material, deduced by observation of emission spectra of HII regions. There is much scatter in these derived nebular abundances, although this is probably mainly due to errors in observation and analysis, and it had originally been thought that this latter gradient was much steeper. But a reanalysis of the spectra assuming that temperature fluctuations in the nebulae are not important (as seems reasonable from recent theoretical modelling) gives a gradient in oxygen

0028-0836/79/3700102-01$01.00

abundance in close agreement with this reinterpretation of James's result. (The reanalysis of the HII regions is discussed by Pagel in *Stars and Stellar Systems* ed. Westerlund, Reidel, 1979.)

If these gradients stay linear to the centre of the Galaxy, they imply a central enhancement over the solar neighbourhood by a factor of × 2.1 as judged by the 'metals' gradient, and a (negligibly different) factor × 2.5 as judged by the oxygen gradient. It may be dangerous to extrapolate so far, but interstellar obscuration makes optical observations in the disk difficult beyond 8 kpc. The extrapolation is anyway in encouraging agreement (within the probable errors) with a determination of heavy element abundances of about three times solar neighbourhood deduced by infrared observations of nebular lines from the Galactic centre (Aitken, Griffiths and Jones, *Mon. Not. R. astr. Soc.* **176**, 73p; 1976). Thus a linear abundance gradient in both stars and gas is indicated, with a factor of 2–3 decrease between the centre and the Sun. This conclusion will be of considerable value in improving estimates of the total gas content of the disk which rely on indirect derivations of H_2 abundance from millimetre-wavelength observations of co-existing carbon monoxide molecules. The interstellar CO abundance should depend linearly on the carbon abundance, given that the Galactic O/C ratio exceeds unity, and determinations have usually assumed a constant C/H ratio (fixed by observations near the Sun) throughout the disk. The H_2 content of the disk may thus be somewhat lower than previously thought.

For the halo, the situation is more uncertain. One of the principal components is the globular cluster system, and controversy has arisen over the existence or non-existence of a correlation between the overall metal abundance of a cluster and its distance from the Galactic centre. Undoubtedly there exists a great range in abundances for clusters at any given distance, but while Searle and Zinn (*Astrophys. J.* **225**, 357; 1978) claim — mainly on the basis of photometry — that there is no overall gradient, Harris and Canterna (*Astrophys. J. Lett.* **231**, L19; 1979) — partly on the basis of a compilation of high-dispersion spectral analyses — claim that there is. Comparison of abundances when stars have been analysed in different ways is always difficult, and resolution of the controversy may have to wait until a complete homogeneous set of analyses is available. The common ground between the two investigations is (1) there is a range in metal abundance of the clusters from solar to 1/100 of solar at all radii out to 10 kpc, and (2) there are no 'metal rich' clusters between 10 and 30 kpc, but a range between 1/10 and 1/100 of solar at any radius in this region. Beyond 30 kpc Searle and Zinn's sample is very small, but Harris and Canterna claim abundances less than or equal to only 1/100 solar out to 100 kpc. They include in their sample the dwarf outlying Draco and Ursa Major systems which are rather more open structures than globular clusters but almost undoubtedly part of the Galactic system. Searle and Zinn argue that, apart from the metal rich clusters which may have formed late in the early evolution of the Galaxy, a lack of gradient is apparent. This, together with the particular form of the spread of abundances at all radii, would indicate that the clusters essentially formed independently as stellar systems, lost gas, and then came together to form the halo. If Harris and Caterna's interpretation is preferred, in that the mean metal abundance at 50–100 kpc is lower than at 10-30 kpc and hence implying some gradient, then the assumption of independence would have to be modified so that the halo had some overall structure before and during formation of the clusters — rather than just aggregating together afterwards.

In the currently popular model, the Galaxy is presumed to have collapsed from a more dispersed state to its present form under the influence of self gravity — a model which, as Searle and Zinn point out, was first proposed by Kant as long ago as 1755. Abundance gradients can be produced easily in reasonably sophisticated computer simulations of the evolution of this model, but exactly what is the dominant process which causes the actual Galactic gradient is still not clear. Analytically, a linear gradient can be understood with the simplest possible model for synthesis resulting from converting gas into successive generations of stars, provided particular (but not unreasonable) radial distributions of gas and star mass are assumed (Pagel, *op. cit.*). But such a model does not give the observed unexpectedly small number of old stars in the disk with low abundances, and radial gas flows during the evolution of the Galaxy will probably have to be involved. The wide spread of abundances in the halo clusters certainly points to a fairly chaotic evolution there. Better knowledge of the spatial variation of element abundance in our own and nearby galaxies is certain to place useful constraints on our ideas of the formation and evolution of galaxies. □

M.G. Edmunds is a Lecturer in the Department of Applied Mathematics and Astronomy, University College, Cardiff.

Erratum

A line was accidentally omitted from the contribution of W.L. Fink and E.O. Wiley in a recent *News and Views* (*Nature* **280**, 542; 1979). In the fifth paragraph, the sentence beginning on the eighth line should read: "The lineage is broken up, naturally and non-arbitrarily, by the many speciation events which have occurred from the Devonian to the Recent."

Moas as rockhounds

from Ian Smalley

THOUSANDS of years before the first human set foot in New Zealand, the now extinct, flightless bird the moa, was roaming the countryside searching for semi-precious gemstones such as agate, opal, chalcedony, chert and jasper. It swallowed suitably sized pebbles of these materials and retained them in its gizzard to grind up its food. The birds carefully chose the hardest available stones and when they had worn smooth they spat them out — for latter-day geologists to find. B.W. Hayward of the New Zealand Geological Survey has reached this conclusion after studying the pebbles found on the sandy hills surrounding the Auckland University Field Club scientific station at Kawerua, on the west coast of Northland (*Tane* **20**, 159; 1978). The pebbles can only have come from the Waimamaku Valley some 5-10 km away; those examined had a mean maximum diameter of 28 mm and were highly polished and rather flattened in shape.

The birds seem to have been highly selective and to have concentrated on collecting and swallowing only the hardest of the local stones; these are the ones which, largely because of their hardness, fall into the semi-precious category. Before the arrival of man there must have been vast numbers of moas roaming New Zealand and they have left widespread and abundant deposits of used gizzard stones. In fact it seems that moas were common enough to have significantly affected the nature of the New Zealand vegetation, and the plant types seen today show the effects of long-term moa browsing (Greenwood & Atkinson *Proc. N.Z.Ecol.Soc.* **24**,21; 1977). The gizzard stones are virtually always varieties of quartz and exceptions have been observed in only two localities. The moas found in the well-known deposit at Pyramid Valley, North Canterbury used greywacke stones. This valley passes through Tertiary limestones and soft sandstones with greywacke exposed in the headwaters. There seems to be no nearby source of quartz and the next most resistant rock type available is greywacke; a similar situation exists for the stones from near Lake Tekapo.

At Kawerua one of the richest localities for finding pebbles is around the actively eroding Pukenuiorongo Bluffs. The Bluffs are 120 m above sea level and consist of a series of large washouts exposing a 40 m thick sequence of Pleistocene sands. This sequence probably accumulated on land as there is no evidence of water deposition

---

Ian Smalley is with the Soil Bureau, Department of Scientific and Industrial Research, Lower Hutt, New Zealand.

0028-0836/79/3700103-02$01.00

and although none of the sandstones preserves any laminations or crossbedding typical of dune deposits, they are probably wind blown accumulations having advanced inland from the coast. The stones were presumably coughed up by the moas in the sandy coastal areas and buried by the advance of the dune sand.

The pebbles collected from Pukenuiorongo Bluffs are generally flatter and more rounded and polished than most of the authenticated moa gizzard stones which are usually found in association with moa skeletons. This supports Hayward's hypothesis that the collected pebbles were supplied by live moas who coughed them up when their grinding efficiency was significantly reduced. Hayward also proposed that the moas sought actual rock types — even though the majority of the quartzose pebbles are gleaming white and easily distinguished the moas detected and swallowed numbers of brown, red and black pebbles of similar lithologies. It seems that the birds made their selection after a careful mineralogical assessment. □

Evidence for gluons?

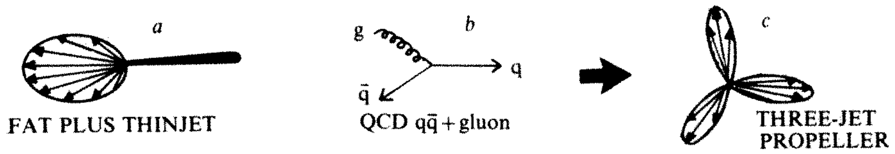
from Frank Close

THE latest results from PETRA, the Hamburg electron positron colliding ring, appear to add considerable weight to the quantum chromodynamic theory of the interquark force. Quarks are hypothesised to possess a new form of charge, known as colour, and interact with one another by exchanging coloured gluons (this process being somewhat analogous to the way that electrically charged objects mutually interact by exchanging photons). Just as the photon is the quantum of the electromagnetic force so are coloured gluons the quanta of the chromodynamic or interquark force. The theories of these forces are respectively quantum electrodynamics (QED) and quantum chromodynamics (QCD), the similarity in their names bearing witness to the similarity in their mathematical structures.

When electrons are annihilated by their antimatter (positrons) the energy is converted into light (this is well described by QED). This light lives for only a fraction of a second before being transformed into particles. Sometimes the light reconverts into leptons and antileptons (like the electron and positron). Alternatively the light may become a quark and an antiquark (q and $\bar{q}$). This process is conventionally denoted

$$e^+e^- \to \gamma \to q\bar{q}$$

So far everything is described by QED. In both cases electrical charges are being accelerated (positive and negative have been produced out of nothing) and QED predicts that quanta (photons) will be radiated by the produced charged particles (the lepton pair or the quark and antiquark). This is indeed the case experimentally and has been well understood for many years.



QCD for colour carriers is analogous to QED for charge carriers. Therefore it may be no surprise to learn that when colour charges are accelerated the theory predicts that gluons will be radiated. Quarks and antiquarks carry colour and so the real process is

$$e^+e^- \to \gamma \to (q + \text{photons} + \text{gluons}) + (\bar{q} + \text{photons} + \text{gluons})$$

From established QED we can calculate how much of the signal is due to the photon radiation. This then makes possible a study of the characteristics associated with gluon radiation from coloured quarks and comparison with the QCD predictions. There are three qualitative types of phenomena expected, one of which was only becoming apparent earlier this year (*Nature* **277**, 349; **280**, 450) and the third of which now appears to be showing up in the most recent Hamburg experiments.

(1) It is possible that the quark and antiquark may bind together and form a vector meson, like the J/ψ or Υ mesons, until such time as they annihilate one another thereby causing the meson to die. QCD predicts two things here. First, the probability for the quark and antiquark to annihilate decreases as the mass or energy of the $q\bar{q}$ bound state increases. This is apparently seen in tht the J/ψ (3.1GeV) and Υ (9.5GeV) have anomalously enhanced lifetimes compared to what would have been expected in the absence of QCD based on the known lifetime of the lighter ϕ(1.0GeV).

Second, it makes predictions as to the distribution in energy and space of the particles that are produced in the decay. The theory requires that the quark and antiquark annihilate, thereby producing three gluons. These gluons then transmute into pions and kaons that are detected by the experimental apparatus; three jets of particles should be detected bearing witness to the memory of the three gluons.

The J/ψ at 3GeV is too light to allow a good test of this prediction. Studies of the more massive Υ early in 1979 began to provide data supporting the three-jet prediction (*News and Views* **277**, 349; **280**, 450). The best tests of this prediction may have to wait until (if?) a yet heavier vector meson (θ) is discovered, a bound state of the hypothesised sixth quark (t and $\bar{t}$). Such a meson, (if it exists) appears to be too massive to be produced at the present generation of electron-positron machines.

(2) The energy of the electron-positron annihilation might not be suitable for a vector meson to be simply produced. In this case the q,$\bar{q}$ and associated glue are radiated off away from one another.

QCD predicts that, at high energies, the most likely configurations are where the quark and antiquark carry off most of the energy and the glue is either very soft or highly collimated along the $q\bar{q}$ axis. As a consequence two jets of particles will be seen in the detectors.

Such 'two-jet events' have been known to exist for about 5 years. QCD predicts that as the electron-positron annihilation energies increase, so these two-jet events will become increasingly collimated and pencil-like. Data at the highest energies indeed support this.

(3) Although these jetlike — pencil — events should dominate, there is a chance that the quark (or antiquark) radiates a hard gluon which carries off momentum and deflects the quark (antiquark) from its path (Fig 1*a*). If resolution is poor this will show up as a thin-jet plus fat-jet event, like a squash or tennis racket (Fig. 1*a*). Evidence for such events was reported by the TASSO collaboration at the CERN conference in June.

The latest results from PETRA are obtained with it operating at the highest energy of 32GeV. The events are dominantly two-jet in character but a significant number of planar tennis racket type were seen. Some of these do appear to be resolvable into a genuine three-jet structure (Fig 1*c*) (known as propeller or Mercedes events — the German laboratory inspired by the manufacturers symbol). These latest results were announced at a conference at Fermilab, Chicago during the final week of August.

So it appears that, at least qualitatively, the behaviour of high energy electron-positron annihilation does mimic the expectations of QCD, the theory of the interquark force. Theorists and experimentalists suspect that these three-jet events are due to a quark radiating a gluon before the detected particles are created Figure 1*b* shows the $q\bar{q}$ gluon state, which then becomes particles like pions and kaons by an unknown mechanism. However, there is much quantitative work still to be done by experimentatists, and theorists will be trying to find more precise tests. With more work at the highest energies, PETRA seems well set to be able to perform a significant test of the theory. □

review article

Structure and evolution of the Moon

Stuart Ross Taylor

Research School of Earth Sciences, Australian National University, Canberra, Australia

The scientific investigation of the samples returned by the Apollo and Luna missions, together with geophysical and photogeological data, has provided a reasonably complete understanding of the structure, composition and evolution of the Moon, and has placed many constraints on theories of its origin.

THE tenth anniversary of the first of the manned Apollo missions (20 July 1969) to the Moon provides an appropriate opportunity to review the current state of our knowledge of the structure, composition, evolution and origin of the Moon. Much of our scientific understanding stems from the samples obtained during the Apollo missions. Coupled with the various geophysical and photogeological information also obtained, and reinforced by the unmanned missions to Mars, Mercury and Venus, the result has been the development of the science of planetology. Insights into the origin of the Solar System, the composition of the solar nebula, and the relation of the Earth to the other members of the inner parts of the Solar System have all been obtained. The current state of lunar and planetary science is illustrated by over 50,000 pages of literature written since 1969. The latest additions to this mountain of data are the 1,426 pages of abstracts of papers for the tenth Lunar Science Conference held in Houston, Texas, in March 1979. Within the limits of this survey, it is not possible to reference adequately all this material, or to do justice to many of the important scientific results. Some critical and interesting areas (soils, track studies, rare gases, and meteorite flux) have had to be excluded because of space limitations.

Internal structure

Models for the internal structure of the Moon down to depths of 1,000 km have now reached a consensus (Fig. 1). The lunar crust, which is less dense than, and chemically distinct from the interior, varies in thickness from 60 km to 100 km. These values are constrained partly by density[1] (crustal density = 2.96 g cm^{-3}), but also by some seismic evidence for the base of the crust[2,3]. The mare basalts, although prominent visually, constitute less than 1% of the crustal volume (0.1% of lunar volume). The highland crustal thickness is 60 km at the Apollo 12 site and 75 km at the Apollo 16 site. A 20-km discontinuity within the crust does not reflect the base of the mare basalts, but rather the depth of fracturing or of closure of cracks produced by the large collisions, thus representing the change from fractured to competent rock[2,3].

The upper mantle or lithosphere extends from the base of the crust (60–100 km) to 400–500 km. The average P wave velocity (V_p) is 7.7 km s^{-1} and the average S wave velocity (V_s) 4.45 km s^{-1}, with negative velocity gradients. There is some inconclusive evidence for lateral heterogeneity[4]. A minor discontinuity exists[2,3], most probably located at a depth of 480 km, with a change to lower seismic wave velocities (V_p 7.6 km s^{-1}; V_s 4.2 km s^{-1}) down to depths of about 1,000 km. Deep within this zone (800–1,000 km depth) occur most of the moonquakes. A few (so called high frequency teleseismic events) occur at depths of about 100 km, most probably associated with deep fractures surrounding the ringed basins[5]. The crust itself is aseismic. Below 1,110 km, the structure becomes less certain. P and S waves become attenuated (V_p ~5.0 km s^{-1}; V_s 2.5 km s^{-1}), consistent with the presence of a small amount (~1%) of melt. There is a major discontinuity at about 1,110 km, with a very sharp decrease in S wave velocities[2,3].

A lunar core? The possible existence of a lunar core has been much debated but the evidence for it remains inconclusive. The seismic data restrict the core radius to 170–360 km (less than 2% of lunar volume)[6]. The lunar coefficient of moment of inertia[7] constraint ($1/MR^2 = 0.391 \pm 0.002$) requires a density increase in the deep interior, in addition to the low density crust. Although such a constraint may be satisfied by a core, it is also satisfied by a density increase at the 480 km discontinuity to a more iron-rich interior[2,3].

The restrictions on core size to about 2% of the lunar volume make such a core of little geochemical significance, for example as a sink for the siderophile elements. The presence of a core implies complete lunar differentiation. Most of the evidence (discussed in later sections) favours initial melting of half or two-thirds of the Moon rather than a completely molten body.

Whether such a small core could have generated a magnetic field, via conventional dynamo action, remains uncertain, as do the origin and intensity of the ancient lunar magnetic field. The surprising initial observation that the returned lunar samples possessed a stable natural remanent magnetisation (NMR), which indicated the former presence of a now vanished magnetic field, has continued to baffle investigators. Considerable efforts have been made to determine the palaeointensity of this field, and there is general agreement that fields up to 1 Oe were required on the lunar surface to account for the NMR[8–10]. Some evidence exists for a decay in field strength over about two orders of magnitude between 4,000 and 3,000 Myr but the evidence, particularly from the breccias, is still a matter of controversy[9,10]. This is leading to a concentration of effort on the mare basalts, which possess a much simpler history than the complex breccias[10]. Debate continues about the local or Moon-wide nature of the field[11]. Resolution of this problem may have to await a future lunar orbiter. The locally varying magnetic anomalies observed by the orbiting subsatellites during the Apollo 16 mission definitely correlate with ejecta blankets from the ringed basins and older large craters[12]. The youngest identifiable area yielding such an anomaly is the feature Reiner gamma, dated stratigraphically at 2,900 Myr.

0028-0836/79/370105—06$01.00

The origins proposed for the lunar magnetic field encompass a large number of processes, which fall within the following categories: (1) the field is random due to localised near-surface origin[13]; (2) external uniform fields; (3) internal dipole field[4]. No resolution seems possible at present between these alternatives[10]. Note that attempts to relate the lunar field to the presumed interplanetary field responsible for the fossil magnetism observed in meteorites may be misleading. Among other caveats, the fields responsible for the magnetic effects in meteorites were in existence about 1,000 Myr earlier than those responsible for the lunar magnetism[14].

The lunar highlands

Crustal densities, based on orbital γ-ray data for iron, are consistent with models of uniform density and variable crustal thickness (Airy-type model) rather than the reverse (Pratt model[15]). Contrary to earlier interpretations[16], the Apennine Mountains, rising 7 km about Mare Imbrium, may be isostatically uncompensated, supported by the lunar crust and lithosphere for 3,900 Myr[17]. Coupled with the mascon data, this provides a constraint on lunar thermal models and on the strength of the lunar interior. Partial melting in the interior, which produced the mare basalts as late as 3,200 (or 2,600) Myr, did not weaken the upper lithosphere sufficiently to allow isostatic compensation. Younger large lunar craters (for example, Copernicus) show negative gravity anomalies (that is, net mass deficiency) but older craters such as Humboldt do not[18]. The possibility that the older craters are isostatically compensated is not consistent with the presence of the uncompensated Apennines. Possible explanations include the reduction of porosity in the subcrater structure by shaking during the Imbrium and Orientale basin forming collisions at 3,900 Myr, or the intrusion of mare basalt as sills and dykes into the fractured subsurface structure.

The large ringed basins (with up to five concentric mountain rings as for Orientale) owe their origin to collisions of asteroids or planetesimals. The energy release during the Imbrium collision has been estimated[19] at about 3×10^{33} erg (corresponding to the impact of a 100-km diameter asteroid of density 3 g cm^{-3} travelling at 16 km s^{-1}), about two orders of magnitude less than the energy required to disrupt the Moon[19]. Opinion has been divided between an origin of the outer rings by the initial cratering episode or by later slumping along concentric faults. The present view based on cratering experiments[20] is that the rings formed, like nested craters, during the impact[21–23].

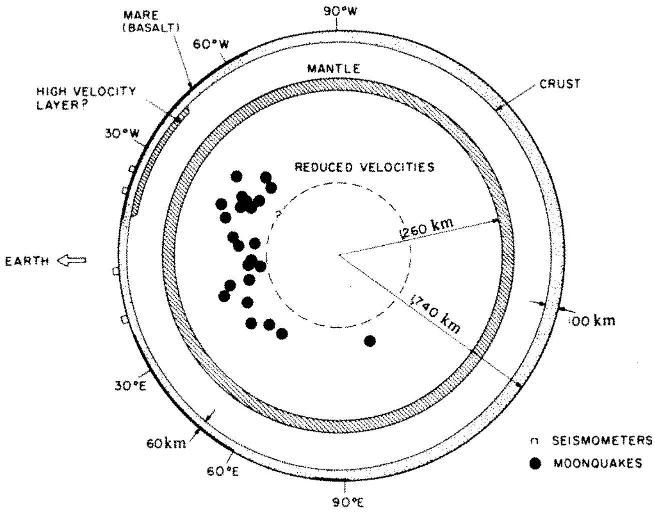

Fig. 1 Internal structure of the Moon[2,3], consisting of a 60–100-km thick crust overlying a two-layered mantle, or lithosphere, with a transition zone between 400 and 480 km. Epicentres of typically observed moonquakes are shown. The inner region, within the dashed circle, shows a sharp decrease in P and S wave velocities. (Courtesy N. E. Goins.)

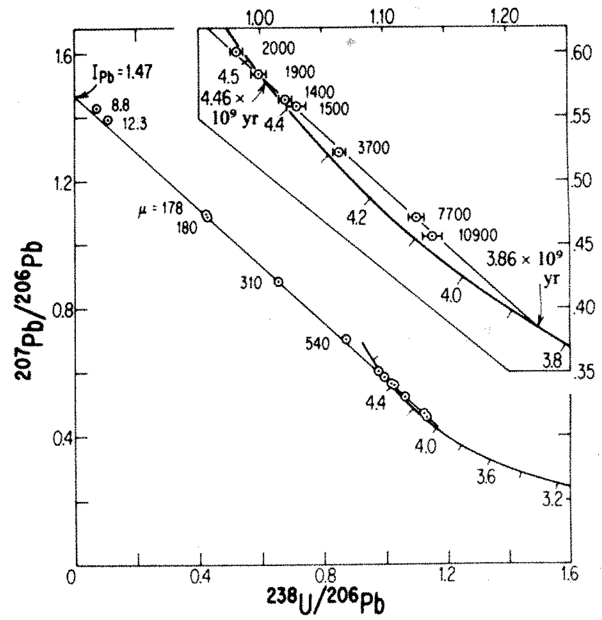

Fig. 2 U–Pb evolution diagram for highland breccias[28]. Inset shows data points near concordia curve with error bars. The measured value of $\mu = {}^{238}\text{U}/{}^{204}\text{Pb}$ is given for each sample. Of 13 data points, 10 lie precisely on a line intersecting concordia curve at 4,460 Myr and 3,860 Myr. The upper intersection represents the time of early lunar differentiation and crust formation. The lower intersection corresponds to a time of intense bombardment of the Moon (terminal lunar cataclysm). Samples whose data points do not plot precisely on the line may have impact ages slightly different from 3,860 Myr. The cataclysm affected almost all lunar highland rocks, causing severe U/Pb fractionation in the breccias. This is reflected by the linear distribution of the data points on the graph and the strong correlation of μ values with position of the data points. (Courtesy F. Oberli and G. J. Wasserburg.)

The depth to which the impacts which produced the giant ringed basins have excavated and overturned (and thus sampled) the crust remains uncertain. Estimates have ranged from minimum values[24] of 8–27 km to depths exceeding the thickness of the lunar crust[25]. An upper limit is provided by the lack of material collected from beneath the feldspathic crust. The dunite (72415) which is sometimes so described has a mineralogy indicative of shallow, rather than deep, origin[26]. It may have originated either as a cumulate, crystallising in a pool of impact melt, or, more probably, on account of its old age (4,600 Myr), from liquid trapped in the feldspathic crust, or possibly in a frozen primordial crust. It is thus of doubtful use as an index of the composition of the lunar mantle.

The mechanics of formation of the giant ringed basins are critical for the interpretation of the samples returned from the lunar highlands. Sampling of the 'light plains' units in the highlands (at Apollo 16) demolished the theory that they were of volcanic origin. They are due to the widespread transport of debris across the lunar surface, during the excavation of the giant ringed basins. However, the primary basin ejecta does not blanket the pre-existing surface for more than a short distance from the basin rim. The secondary projectiles flying out from the explosion plough up the surface and create their own local ejecta. The result is that the light plains units are mainly composed of locally derived debris. Thus, the ejecta blanket from the Imbrium collision, which was sampled at the Fra Mauro site during the Apollo 14 mission, although intensely brecciated, does not show the effects of the more than 200 kbar shock pressure which existed at the centre of the Imbrium basin during impact[27]. The orbital γ-ray and X-ray fluorescence data show much variation across the highlands, consistent with local chemical variability and with the above model.

The date of the formation of the lunar highland crust has been refined as a result of lead isotope investigations (Fig. 2). These isotopic data show two ages, one at 4,460 Myr, which is interpreted as the age of formation, and a second at 3,860 Myr consistent with the age of the Imbrium collision[28]. These new dates place the crystallisation of the highland crust a little earlier than the 4,400 Myr previously accepted. As the date for the condensation of the Solar System is usually given as 4,570 Myr[29], accretion of the Moon followed by melting and crystallisation of at least half the lunar volume, was accomplished very quickly.

The overall composition of the lunar highland surface is given in Table 1. It is highly fractionated with respect to either primitive solar nebula compositions or to the bulk composition of the Moon (Table 1). Although early workers were so impressed by this refractory alumina-rich composition as to suggest a late, heterogeneous accretion episode to account for it, all geochemical and petrological evidence now links the highland crust to the rest of the Moon. For example, the similarity in the ratios of volatile/refractory elements (for example, K/Ba, K/Zr, K/U) in all returned lunar samples[30] indissolubly links the highlands and the mare samples derived from the lunar interior.

The question of whether a feldspathic crust would float over a crystallising 'magma ocean' was resolved by experimental results[31] which demonstrated that such flotation would occur in the anhydrous lunar environment in liquids parental to the highland crust. No report of water on the Moon, even at the level of parts per 10^9 (p.p.b.), has been substantiated. This contrasts with the terrestrial situation, where the presence of small quantities of water causes the feldspar to sink. This, among other factors, invalidates the case for an early anorthositic crust on the Earth[32,33].

Detailed models for the crystallisation of the magma ocean[34–36] indicate that such processes were complex, probably involving the formation of 'rockbergs' (analogous to icebergs), cycles of assimilation and mixing, and trapping of interstitial liquids to produce the complex suite of crustal rocks. It is probable that an extensive bombardment continued throughout the formation of the crust and for the next 500–600 Myr, culminating in the terminal cataclysm at about 3,900 Myr to which the Imbrium and Orientale basins bear witness. The complexity of the resulting rock types has led to a literature too extensive to review here (see, for example, ref. 37).

In addition to the feldspathic (anorthositic) and primitive Mg-rich components in the lunar crust, a third, known as KREEP, is pervasive. Its origin has been widely debated since its discovery at the Fra Mauro site during the Apollo 14 mission (following traces reported from the Apollo 12 landing site). The continuing bombardment which pulverised the crust has destroyed most of the evidence. One view considers that the KREEP basalts are derived from flows representing pre-mare volcanism[27]. The absence of identifiable rocks (except for those crystallising from impact melts) makes this view, based on photogeological interpretation, less likely than the other extreme, which relates the origin of KREEP to the crystallisation of the magma ocean. In this model, the extremely high concentrations of such components as K, rare earth elements (REE), P, Ba, Th, U and Zr are derived from the residual melt following crystallisation of the magma ocean[38]. This model is reinforced by the Sm–Nd systematics[39] which indicate a uniform origin for KREEP at the different landing sites, and by the parallel REE patterns independent of total REE abundance which typify many highlands samples[40].

The mare basalts

Such models for the origin of the crust are related to the question of the source of the dark mare basalts, which have been remarked on in most mythologies. They cover 17% of the lunar surface, although only rarely (in the centres of ringed basins) exceeding thicknesses of 1 km (refs 41, 42). Their concentration on the Earth-facing hemisphere, where the crust is thinner (Fig. 1) is probably a consequence of non-uniform crustal thickness[43]. The mare basalts are derived by partial melting from depths of 100–400 km. Hence, they provide, in principle, information about the composition of the deep interior and so the nature of their source regions has been keenly debated.

Several recent reviews have appeared[44–47] which delineate nearly 20 types ranging from high titanium to very low titanium (VLT) basalts. Most of these types cannot be related simply by partial melting or by fractional crystallisation from a single parent magma, but demand differing source compositions. The nearly ubiquitous depletion in Eu demonstrates prior removal from the source regions of plagioclase. Isotopic systematics (Rb–Sr and Sm–Nd) (see, for example, ref. 48) indicate crystallisation of the source regions at or before 4,400 Myr, hundreds of millions of years before their eruption. Dated flows extend

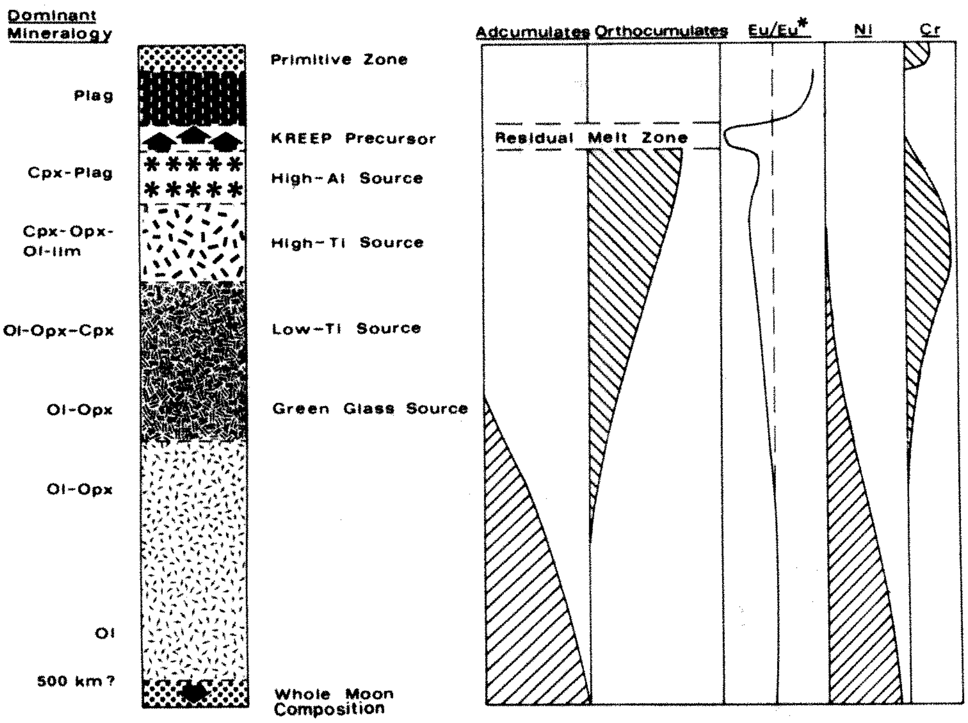

Fig. 3 Schematic diagram to illustrate formation of a mineralogically zoned source region for the lunar mare basalts, during crystallisation of a 500-km deep magma ocean. Adcumulus growth (that is, little trapped pore liquid) predominates at depth, with orthocumulus growth (incorporation of trapped interstitial liquids) occurring at higher levels. The Eu anomaly (Eu/Eu*) increases to a maximum negative value in the KREEP precursor zone, and is positive in the floating plagioclase crust. Nickel is concentrated in olivine-rich zones in the deep interior. Chromium, possibly mainly divalent[61,62], is concentrated in the source regions of the mare basalts. (Adapted from ref. 57.)

from 3,900 Myr to 3,160 Myr[40]. Mare volcanism probably began earlier, before the final cataclysmic collisions, both from photogeological studies[48] and the presence of basalt clasts in Apollo 14 breccias[40]. The style of eruption is analogous to terrestrial plateau or flood basalts. The combination of low viscosity and high flow rates[50] produced the characteristic smooth (±150 m) surfaces of the mare basalts[51]. The impacts which formed the large basins, although producing some local melt[52], did not initiate the floods of basalt from the lunar interior. These were erupted up to hundreds of millions of years after the great collisions. Among the new types of basalts[47,53–55] described recently, the most significant are the Apollo 17 VLT basalts[55]. These display the high V and Cr and low Ni contents typical of most mare basalts, but in addition have heavy REE (HREE)-enriched patterns, rather than the flat or depleted patterns common to other species. The REE patterns, which include a negative Eu anomaly, preclude derivation either from a primitive interior, or by assimilation of crustal or cumulate material[55].

When contemplating the whole spectrum of basalt types, derivation from a cumulate source region remains the most promising model. The crystallisation of the magma ocean produces a layered series of differing mineralogy, ranging from olivine and orthopyroxene at the base to clinopyroxene–ilmenite cumulates at shallower levels (Fig. 3). Trapping of interstitial liquids, convective overturn, magma mixing and other processes[35] will greatly complicate the simplified models originally envisaged[38] but the overall concept accounts for both the isotopic systematics and trace element abundances. The total absence of water and other volatile components means that small-scale heterogeneities in the lunar interior will remain frozen in. A consequence is that mare basalt compositions (even the most primitive such as Apollo 15 green glass[56] or Apollo 17 VLT basalts[55]) are derived from fractionated source regions and do not provide direct information on the primordial lunar composition.

Much progress has been made in mapping mare basalts from the orbital chemical data[58] and by remote sensing techniques[59]. The youngest mare basalts, identified in Western Oceanus Procellarum by photogeological techniques, are about 2,600 Myr old[60]. After this time, no lavas reached the surface. The melting of mare basalts in the interior was fuelled by trapped K, U and Th, although most of the lunar budget for these radioactive elements was concentrated in the crust by the early differentiation.

A frozen surface. The cessation of mare basalt flooding at 2,600 Myr caused the last discernible changes to the lunar surface (Fig. 4) except for the production of younger impact craters, such as Copernicus, Kepler, Aristarchus and Tycho. The last major structural change to the lunar surface occurred at 3,900 Myr with the production of the 900-km diameter Orientale ringed basin, with an energy release[19] estimated at 1.4×10^{33} erg. Since that event, the lunar surface shows no evidence of major tectonic activity, expansion or contraction (except for minor adjustments around the edges of the maria), enabling limits of ±1 km to be applied to the change in lunar radius over the past 4,000 Myr[63]. This lack of change rules out current claims for massive increases in Earth radius[64] and restricts the rate of change of G ($-\delta G/G\ \mathrm{yr}^{-1}$) to $\leq 5\times10^{-11}$ in constant mass cosmologies, and to $\leq 1.5\times10^{-10}$ in variable mass cosmologies[65].

Lunar composition

The overall composition of the Moon is of particular interest because of its possible relationship to the Earth. The highly fractionated nature of the lunar samples to which we have access place constraints on all models. The heat flow[66] measured at the Apollo 15 and 17 sites is consistent, for a steady-state model, with bulk lunar uranium contents in the range 35–46 p.p.b. A non-steady-state solution could reduce these values by about 20% (ref. 67). A bulk lunar U content of about 40 p.p.b. is estimated from geochemical balance considerations[68]. From correlations among refractory elements (Ca/Al/Ti/U ratios), from K/U systematics (K/U = 2,500) and from the lunar density (3.34 g cm^{-3}) which constrains the Fe content, it is possible to arrive at compositions which satisfy the density, moment of inertia and heat flow constraints. An average of such compositions is given in Table 1. Melting of the outer half or two-thirds of the Moon of such composition gives rise to the feldspathic lunar crust[35] as well as a zoned interior capable of producing the mare basalts by partial melting. The depth of initial lunar melting[57,63] is most probably 300–500 km. If the seismic discontinuity[2,3] at 480 km is identified with the base of the melted zone, then the seismic velocity decrease (Fig. 1) and the coefficient of moment of inertia value, are consistent with a change to a primitive unfractionated iron-rich interior. The lower portions of the melted zone will be dominated by Mg-rich olivine and orthopyroxene so that a sharp break in seismic velocities is expected. In this model, partial melting in the deep

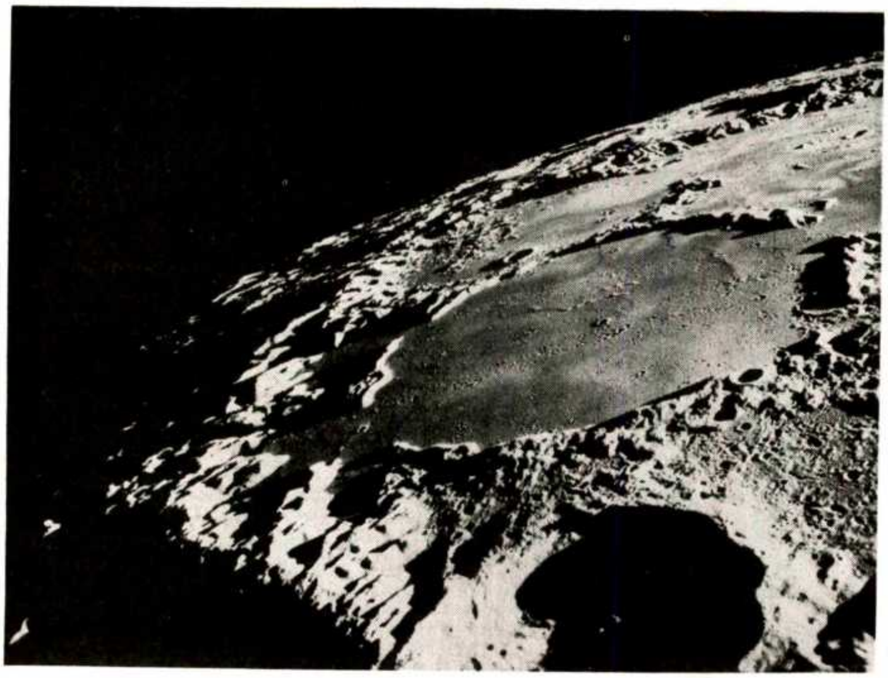

Fig. 4 Farside lunar maria and highlands. The large circular crater, filled with mare basalt, is Thomson (112 km diameter) in the northeast sector of Mare Ingenii (370 km diameter, 34° S, 164°). The large crater in the right foreground is Zelinskiy (54 km diameter). The stratigraphic sequence, from oldest to youngest, is (1) formation of highland crust, (2) excavation of Ingenii basin, (3) formation of Thomson crater, (4) formation of Zelinskiy, (5) flooding of Ingenii basin and Thomson crater with mare basalt, (6) production of small craters on mare surface including a probable chain of secondary craters (NASA AS15-87-11724).

interior is caused by the primitive component of K, U and Th.

Tektites. The disproving of the hypothesis of the lunar origin of tektites must be counted among the minor successes of the Apollo missions. Recent attempts to revive the hypothesis that they are derived from young lunar volcanoes[69] encounters similar problems (for example, one to two orders of magnitude age discrepancy, chemical and isotopic distinctions, lack of observed Tertiary lunar volcanoes) to those which ruled out an origin by meteorite splash from the Moon[70].

Lunar origins

The earlier debate over homogeneous versus heterogeneous accretion of the Moon was resolved in favour of the former hypothesis[30,40]. Homogeneous accretion of a refractory-rich, and volatile and siderophile element-poor Moon, was followed by extensive melting. The evolution of the Moon is thus well understood, but the pre-accretion scenarios remain indistinct. The three principal pre-Apollo hypotheses all encountered difficulties when confronted with the new data.

Little progress has been made with simple versions of the double planet theory but the oxygen isotope data, perhaps the most significant single cosmochemical observation in the past few years, indicate a close association between the Earth and the Moon[73]. The depletion in the refractory siderophile elements forbids direct accretion from the solar nebula, so that one or more stages of element fractionation are needed between condensation of the nebula and accretion of the Moon. The location of these events is obscure.

Capture of an already formed Moon has a *deus ex machina* flavour, and has been deemed 'horrendously improbable' (ref. 74). Such an origin, in a different part of the solar nebula, could be predicted to produce some distinct chemical or isotopic signature. In this context, the oxygen isotope data[73] may have dealt a fatal blow to the capture hypothesis, by requiring formation of the Earth and Moon in close association. Nevertheless, the presence of fractionated meteorites (enstatite achrondrites and aubrites) with similar ^{16}O enrichments, and the close similarity of the howardites and eucrites to the terrestrial values must engender caution, as more efficient mixing may occur in planetary size bodies. Acquisition of oxygen isotope data from other planets should be accorded a high priority, along with age dating, for future sample return missions.

Fission from the Earth has been extensively debated, because in principle, an evaluation of the theory can be achieved by comparison of lunar compositions with that of the terrestrial mantle. This task is in fact complex, partly due to our lack of understanding of the lateral and vertical variations in the composition of the terrestrial mantle (for an extensive recent review see ref. 75). The siderophile element abundances are particularly crucial, but the reasons for the high abundances of such elements (for example, Ni) in the upper mantle of the Earth remain obscure. It is clear that the terrestrial upper mantle has not been in equilibrium with the core of the Earth[72]. Possibly, the high abundances of elements such as Ni are derived from a post-accretion meteoritic bombardment of the Earth[76–78] analogous to such early events on the Moon, Mars and Mercury.

Whatever the cause of the terrestrial siderophile element abundance patterns, the concentrations of refractory siderophile elements Os, Ir, Ni, Pd and Re are enriched by large factors in the Earth compared with the Moon[79]. Au, Sb and Ge are depleted by factors of about 100 in the Moon while the very volatile elements (Bi, Tl, In) show rather uniform depletions of about 50 in the Moon[79]. The alkali elements K, Rb and Cs similarly show depletions by factors of about 2 between the Moon and the mantle of the Earth (Table 1). All these comparisons are complicated by the differing evolutionary histories of the Earth's mantle and the Moon. Simple comparisons, for example, of basalts from both bodies, encounter this problem. Elements such as K and U whose bulk composition can be estimated from a variety of techniques (K–Ar systematics, K/Rb/Sr, Ca/Al/U ratios and heat-flow values) are useful in this context[71]. Terrestrial bulk U values of 15–20 p.p.b. are a factor of 2 lower than the lunar abundances (Table 1). Similar constraints apply to the refractory elements Ca, Al and Ti. The Moon also contains more Fe and less Mg than the Earth's mantle (Table 1).

Table 1 Composition of the lunar highlands, the bulk Moon and the Earth's mantle

	1	2	3	4
SiO_2%	45	42	46.1	45
TiO_2%	0.56	0.4	0.2	0.16
Al_2O_3%	24.6	8.0	4.3	3.3
FeO%	6.6	12	8.2	8.0
MgO%	8.6	31	37.6	40
CaO%	14.2	6.0	3.1	2.6
Na_2O%	0.45	0.1	0.4	0.2
K (p.p.m.)	600	80–100	250	150
U (p.p.b.)	240	30–40	—	15
Th (p.p.b.)	900	120–150	—	60
K/U	2,500	2,500	—	10,000

1, Lunar highlands surface[40]; 2, bulk Moon[71]; 3, Earth's mantle[72]; 4, Earth's mantle[71] (NiO = 0.26, Cr_2O_3 = 0.44). p.p.b. = parts per 10^9.

Thus, the weight of the chemical evidence seems to indicate that the terrestrial mantle and the Moon differ substantially in composition for many elements, refractory, volatile and siderophile. The similarity in chemistry between the eucrites and the lunar basalts indicates the existence of similar processes elsewhere in the inner Solar System[80,81]. The recent demonstration[82] that the siderophile and volatile element contents of the shergottite meteorites mimic those of terrestrial basalts weakens the case for fission. Thus, the initial attraction of the fission hypothesis (the density similarity between the Moon and the terrestrial mantle) is diminished. Accordingly, very complex scenarios have to be devised in order to derive the Moon from the mantle of the Earth[83], or for forming the Moon in close association with the Earth[75,84,85]. The formation of the Moon from a ring of differentiated debris in terrestrial orbit[86,87] during the accretion of the Earth accords most closely with the oxygen isotopic evidence[73].

Epilogue

Could our insights into the composition, age and evolution of the Moon have been obtained from unmanned missions? The answer is no. Such missions would have returned lunar soils. The formation of these soils was not well understood before the Apollo missions. The unravelling of the age, isotopic and chemical evidence which they contain was only possible because individual components (the hand-collected whole rock samples) of these complex mixtures were also available. Our experience gained from the Apollo missions enables us to understand and extract chemical and age information from such samples[47], so that now the scientific examination of an unmanned sample collected and returned from Mars or Mercury could be approached with confidence.

Suspended sediment sources identified by magnetic measurements

D. E. Walling & M. R. Peart

F. Oldfield
Department of Geography, University of Liverpool, UK
R. Thompson
Department of Geophysics, University of Edinburgh, UK

A procedure for identifying the main source of the suspended sediment load of a stream by simple, cheap, rapid and nondestructive magnetic measurements is applicable to samples taken during the routine sampling of flood events permitting general characterisation of the load and more detailed investigation of variations in sediment source both during and between individual flood events.

INFORMATION on the sources of the suspended sediment loads of rivers, and more particularly the relative importance of sheet and rill erosion and channel scour, has many potential uses in studies of sediment transport and sediment yield. For example, it could provide the geomorphologist with a means of elucidating patterns and rates of erosion and afford a means of highlighting potential problems of nonpoint pollution connected with sediment-associated nutrients and contaminants derived from agricultural land. Existing techniques for determining the relative magnitude of these sources have involved detailed documentation of source area erosion[1] and comparison of measured sediment loads with estimates of sediment yield from sheet erosion derived using a soil loss equation coupled with a sediment delivery term[2]. The first approach involves many operational problems and is essentially impossible for anything except small drainage basins, whilst the latter introduces many uncertainties related to the accuracy of the techniques used to estimate sheet erosion and sediment delivery. Furthermore, both approaches provide only long-term aggregate values and do not permit the study and comparison of individual events. Scope clearly exists for alternative procedures and the use of the properties of the sediment load itself as a means of 'fingerprinting' source areas has considerable promise.

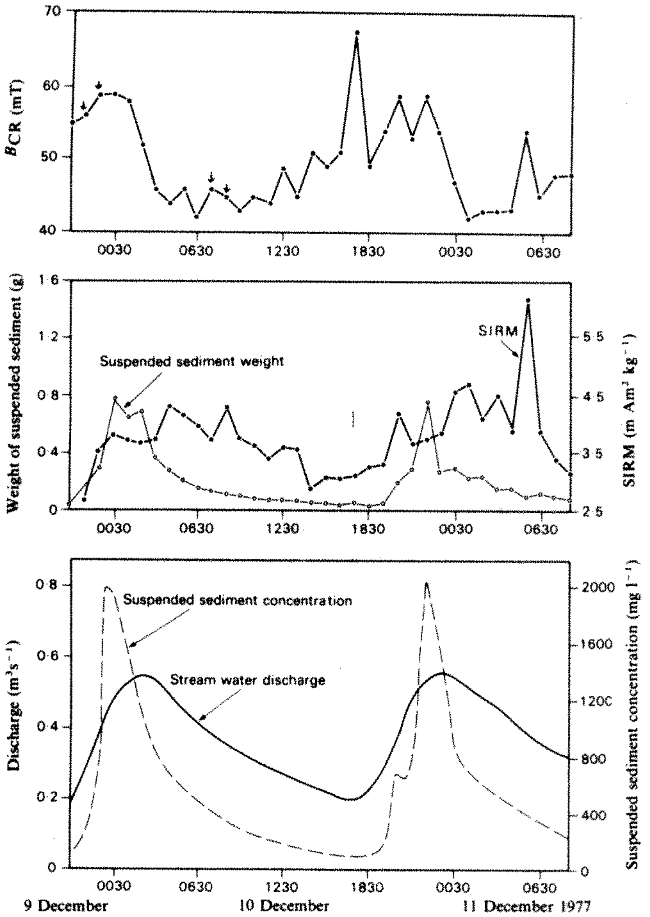

Fig. 1 Variations in B_{CR}, SIRM and suspended sediment concentration measured during a double peaked hydrograph on the Jackmoor Brook. The four samples indexed on the B_{CR} plot are those used to produce the coercivity profiles presented in Fig. 2.

Measurements at Jackmoor Brook

Oldfield *et al.*[3] have previously given preliminary results of an attempt to identify the dominant source of the suspended sediment yield from the Jackmoor Brook basin, an instrumented catchment in south-west England, by comparing the magnetic properties of material from potential source areas within the catchment with those of samples of sediment in transit. Their results showed that bulk magnetic susceptibility (χ), saturation isothermal remanent magnetisation (SIRM), SIRM/χ ratios and coercivity of SIRM (B_{CR}) profiles (Table 1) provide an exceptionally rapid and sensitive basis for differentiating undisturbed woodland topsoil, arable soil, and streambank erosion scars cut into the unmodified Permian bedrock. The processes controlling the transformation of iron compounds which make this type of differentiation possible are poorly understood[4] but in this case they give rise to an alteration of the fine grained weakly ferromagnetic haematite cement in the unweathered parent material to a ferrimagnetic form during soil development. Fire often causes this transformation, although other less dramatic pedogenic processes may also be responsible. The resulting cubic oxide has been identified as either maghemite[5-7] or magnetite[8]. Most evidence suggests that it is impure as a result of isomorphic substitution of iron by other soil cations such as aluminium.

All the magnetic properties previously noted are in some measure diagnostic of this transformation and they permit crude magnetic 'fingerprinting' of different types of sediment source. Oldfield *et al.*[3] showed that the magnetic parameters of the four bulk suspended sediment samples measured were closely comparable to those of cultivated topsoil, but that they differed significantly in several ways from either undisturbed woodland soil or unaltered parent material (Table 1). This suggested that the bulk of the suspended sediment transported by the stream was generated by splash erosion and surface runoff from the extensive cultivated areas of the catchment rather than by channel scour and by erosion of bankside scars. Minor differences in B_{CR} and in SIRM/χ ratios between the individual suspended sediment samples seemed to be related to the discharge conditions prevailing at the time of sampling and the characteristics of the associated storm runoff event. These differences prompted us to look in more detail at variations in the magnetic properties of the suspended sediment transported by this stream both during and between individual storm events.

Transport of suspended sediment

In the previous study, samples of suspended sediment in transit used for magnetic determinations had been obtained by centrifuging bulk samples of stream water (>20 l) and drying the residual solids. More detailed work on individual storm runoff events necessitated a larger number of samples and in view of the operational problems involved in collecting and transporting numerous bulk samples of stream water and the time consuming nature of the laboratory centrifugation procedure, an alternative means of assembling sediment samples for magnetic measurements was sought. It was found that similar measurements could be undertaken on the residue retained on a glass fibre filter circle after filtration of a relatively small volume of river water (~500 ml). The measurements were unaffected by the presence of the filter medium carrying the sediment. Furthermore the samples collected by automatic pump sampling equipment installed at the outflow gauging station of the Jackmoor Brook catchment could be used for this purpose. This equipment, developed from an earlier design[9], collects discrete samples at regular six-hourly intervals and is also triggered to collect samples at hourly intervals when the water stage rises above a preset threshold during storm events. The samples have

Table 1 Summary of selected magnetic properties of bulk suspended sediment samples and potential sediment sources from the Jackmoor Brook catchment

Material	Property χ* (mm³ kg⁻¹)	SIRM† (mA m² kg⁻¹)	SIRM/χ‡ (kA m⁻¹)	B_{CR}§ (mT)	S‖
Woodland topsoil	>2.5	>10	≈4	>20	1
Cultivated topsoil	0.2–2	1–10	5–7	24–41	0.28–0.8
Poorly drained and gleyed soils	0.06–0.4	0.5–3.5	≈10	≈30	≈0.4
Parent material	<0.1	1–2	>10	200–400	−0.8–−0.6
Suspended sediment	0.25–0.75	2.5–9	≈10	37–60	0.06–0.4

* Specific magnetic susceptibility. A measure of the magnetisability of a specimen. Measured in an alternating field of about 0.1 mT peak strength with a frequency of 10 kHz. Mainly reflects the concentration of ferrimagnetic minerals in a specimen.

† Saturation isothermal remanent magnetisation. The magnetisation of a specimen remaining after its removal from a strong (1 T) magnetic field. Mainly reflects the concentration of magnetic minerals in a specimen, but also influenced by the size and shape of magnetic grains.

‡ This ratio reflects the type, size and shape of the magnetic minerals present. For example, it will be decreased by an increasing proportion of ultrafine (superparamagnetic) magnetic grains.

§ Coercivity of remanence. A measure of the stability of the SIRM, being the reverse field required to reduce the remanent magnetisation to zero after saturation in a forward field. Reflects the magnetic mineral type, size or shape, not influenced by concentration.

‖ This ratio of the remanence grown in a back field of 100 mT to the SIRM, mainly depends on the ratio of haematite to magnetite minerals in the specimen. A high S value indicates a relatively greater proportion of magnetite in the sample.

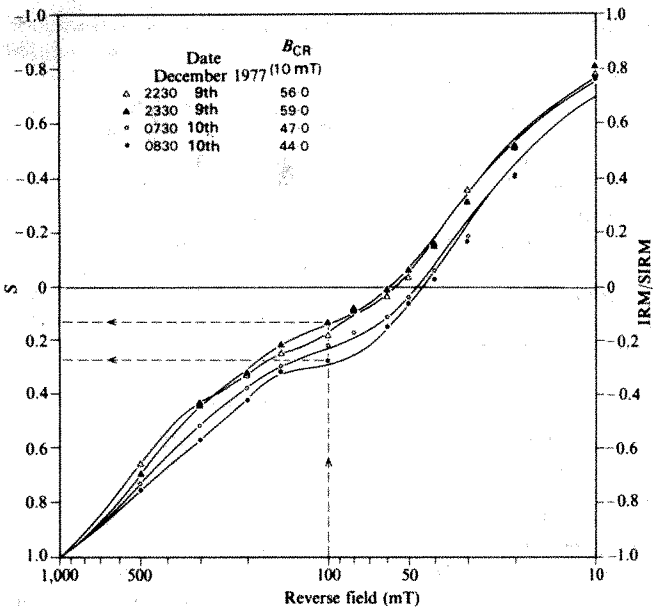

Fig. 2 Coercivity profiles obtained from filter paper residues associated with four samples collected during the storm shown on Fig. 1. Values of S for these samples range from 0.135 to 0.271 and are consistent with the dominance of a cultivated top soil source (Table 1).

been found to be representative of the ambient suspended sediment concentrations at the moment of sampling and may be related to the continuous records of water discharge and suspended sediment concentration (turbidity) available for the gauging site. Samples were therefore collected at frequent intervals during a number of storm events occurring between December 1977 and March 1978.

Samples collected by the automatic sampling equipment were returned to the laboratory for vacuum filtration through pre-weighed glass fibre filter circles (Whatman GFC). Subsequent drying and weighing provided information on the weight of sediment carried by individual filter circles and these were finally moistened, folded, and inserted into polystyrene sample holders with flexible airtight lids.

The SIRM of all resulting samples was determined by placing each one in a 'saturating field' of 1 T and measuring the induced remanent magnetisation (IRM) on a computerised fluxgate magnetometer[10]. The noise level of this instrument was two orders of magnitude below the signal from the least magnetic of the samples measured. The signal from the holder and filter medium was minimised by washing every container and lid in distilled water, by handling samples with clean hands and by keeping both empty and full holders in clean sealed polythene bags. Measurements giving values less than four times the mean signal from empty holders containing clean filter circles were rejected. The consistency of the remaining results encourages confidence in measurements made on samples with dry weights as low as 0.02 g (that is well over 90% of the sample analysed). The SIRM measurements, which are specific to unit mass and therefore independent of sample weight, have been completed for over 160 samples covering discharge conditions ranging from 0.05 to 1.0 $m^3 s^{-1}$ and sediment concentrations ranging from 50 to 2,500 mg l^{-1}. Suites of hourly samples spanning five distinct flood events have been analysed.

For the first suite of samples covering the period 2130 h on 9 December 1977 to 0830 h on 11 December 1977, coercivity of SIRM profiles were also obtained for all of the 36 samples. Figure 1 plots the hourly values of SIRM, B_{CR}, and sediment weight along with the record of discharge and suspended sediment concentration for the event. Coercivity profiles were calculated from measurements of remanence in 10–12 reverse fields of increasing strength. Figure 2 shows representative coercivity profiles drawn automatically from the measurements using a smoothing cubic spline function.

For subsequent sample suites, coercivity measurements were made only on extreme samples for which the SIRM values fell close to the outside limits spanned by the first suite. It was also possible to determine magnetic susceptibility for a proportion of the samples with values above the level of repeatable measurement (1×10^{-7} $m^3 kg^{-1}$) and calculate their SIRM/χ ratios.

The data on the magnetic properties of suspended sediment transported by Jackmoor Brook, assembled using the filter paper technique described above enable us to evaluate variations in these properties both within and between individual events in terms of the sediment sources and erosion processes involved.

Discussion

Figure 1 illustrates the variations in B_{CR} and SIRM measured during a double peaked hydrograph on the Jackmoor Brook. The variations exhibited are typical of most storm hydrographs and indicate a clear tendency for B_{CR} values to decrease during times of increased runoff and sediment concentration and for SIRM values to increase. The range of values shown are very

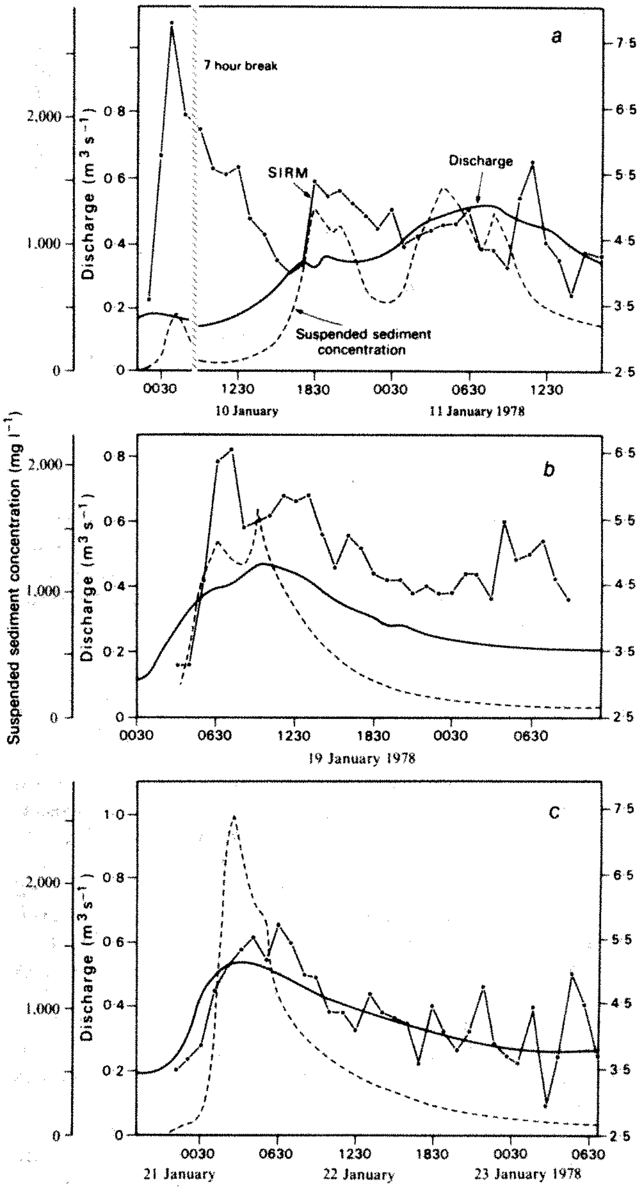

Fig. 3 Variations in SIRM and suspended sediment concentration measured during three storm runoff events on the Jackmoor Brook.

similar to those obtained in the earlier study which suggested that cultivated soils provide the major source of sediment within this catchment (Table 1). Decreasing B_{CR} values and increasing SIRM values indicate a tendency for such sources to become more dominant at the time of the hydrograph peak, because arable soils are marked by higher SIRM and lower B_{CR} values than are the channel-side erosion scars (Table 1). This pattern of variation during the storm hydrograph is therefore consistent with a situation where maximum sediment yields from cultivated areas would coincide with maximum rainfall intensities, maximum surface runoff rates, a maximum area contributing to surface runoff, and therefore the hydrograph peak. Although there is a tendency for the maximum sediment concentrations to precede the discharge peaks in Fig. 1, the maximum SIRM and minimum B_{CR} values occur after the hydrograph peak. This lag effect is again consistent with the sediment sources and process mechanisms that could be postulated for the catchment. Some channel scour must occur and the maximum contribution from this source would be expected to occur during the rising stage of the hydrograph and at the hydrograph peak in response to control by sediment availability and the erosive energy of the streamflow. Many workers[11] have noted that sediment contributions from bank erosion are closely controlled by the loosening of sediment particles during preceding dry periods and that the supply from this source is rapidly depleted. The magnetic properties of the suspended sediment would therefore be most influenced by bank contributions during the earlier part of the streamflow hydrograph and this would delay the occurrence of maximum SIRM and minimum B_{CR} values until after the peak flow had passed. It is tempting to attribute the slight reversal in the trend of increasing SIRM values associated with both hydrograph peaks (0030–0230 and 2030–2330 h on 12 December) to a maximum contribution from channel scour at this time but a more detailed sampling programme would be necessary to confirm the precise nature of this reversal. In addition, the higher SIRM values exhibited by the second hydrograph peak are readily explicable in terms of the depletion of channel sources during the first peak and therefore a lesser contribution from channel scour.

Comparison of a number of individual sediment yield events is also facilitated by the ease with which data from filter paper measurements may be collected and Fig. 3 presents the values of SIRM measured during three storm events which succeeded that documented in Fig. 1. Considerable contrasts in levels of SIRM are apparent between these events but the contrasts are again consistent with a simple process-based conceptual model of the variations in the relative importance of slope and channel sources to the sediment budget of this catchment. The full range of SIRM values (2.8–8 mA m^2 kg^{-1}) indicate that agricultural soils provide the dominant source on all occasions (see Table 1) but relatively low values may be interpreted in terms of proportionally greater contributions from channel scour. The event shown in Fig. 1 was the first major hydrograph of the winter period and might be expected to reflect a relatively high contribution from this source and therefore lower SIRM values. Sediment particles loosened during the preceding dry period would provide a ready supply to channel scour. This source would, however, be rapidly depleted and the higher SIRM values obtained for the two subsequent events (Fig. 3*a* and *b*) may be explained both in terms of lack of sufficient time for the supply to be restored and lower discharges which are less effective for channel scour.

The hydrograph which occurred on 22 January 1978 (Fig. 3*c*) exhibits lower SIRM values than the preceding two events and this feature may be ascribed to the higher discharges involved and therefore to increased channel scour. Higher discharges involve both higher velocities and shear stresses and also submerge greater areas of the channel margin. However, although the discharge peak for this event is of similar magnitude to that of the hydrograph depicted in Fig. 1, the amount of channel scour could be expected to be less than occurred during the first flood event of the winter in view of the depletion effect discussed above and this is confirmed by a comparison of the SIRM values. The very high values of SIRM (up to 8 mA m^2 kg^{-1}) associated with the early part of the storm which occurred on 10 January 1978 (Fig. 3*a*) are also worthy of comment. In this instance the increase in sediment concentration is not related to a significant increase in discharge and it is unlikely that channel scour could be invoked as the source. A localised input from a field source seems more likely and this is consistent with the high SIRM values which may be viewed as being the result of a lack of dilution by sediment from channel sources. Low values of B_{CR} were also evident during this event.

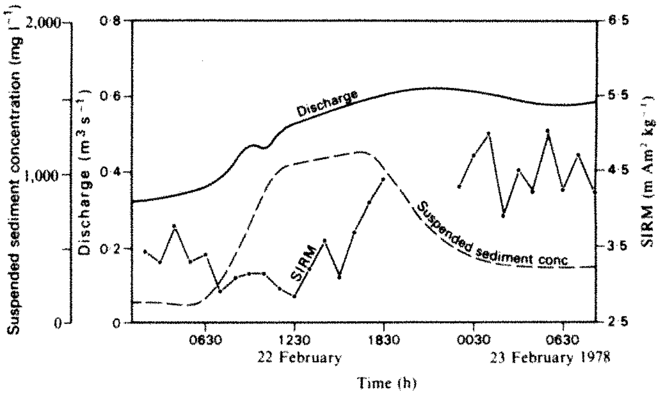

Fig. 4 Variations in SIRM and suspended sediment concentration measured during a snowmelt runoff event on the Jackmoor Brook.

A final example of variation in the magnetic properties of sediment between individual events is given by Fig. 4. This shows a hydrograph which was unusual in having been produced by snowmelt rather than rainfall. The relatively low suspended sediment concentrations may be explained by the lack of rainfall energy, an important component of splash erosion. SIRM values are also somewhat low and this is consistent with a situation unconducive to slope erosion and where channel scour would be of increased relative importance compared to other events.

Conclusions

Measurements of the magnetic properties of suspended sediment in transit can provide a general indication of the relative importance of slope and channel sources to the sediment yield of a catchment, and more specific information on the relative contributions of the individual sources during a storm event and on contrasts in the pattern of sediment generation between particular events. The use of filter paper residues for magnetic determinations provides a simple, effective means of collecting the detailed data required for studies of inter- and intra-storm variations. More work is required on sediment enrichment ratios, on the relationship between magnetic properties and the particle size and organic matter content of suspended sediment, and within catchments draining other rock types, if the potential for using magnetic determinations in studies of sediment sources is to be fully realised.

Fundamental difference between the molecular interactions of agonists and antagonists with the β-adrenergic receptor

Gregory A. Weiland, Kenneth P. Minneman & Perry B. Molinoff

Department of Pharmacology, University of Colorado Medical Center, 4200 East Ninth Avenue, Denver, Colorado 80262

Antagonist binding to the β-adrenergic receptor is largely entropy driven, with only a small enthalpy component. The binding of agonists, on the other hand, is associated with a large decrease in enthalpy which permits a highly unfavourable decrease in entropy. The thermodynamic differences between the binding of agonists and antagonists may provide new insights into the molecular basis for hormone stimulation of adenylate cyclase activity.

THE binding of compounds to the β-adrenergic receptor has been examined in great detail with the use of high-affinity radiolabelled β-adrenergic ligands such as ^{125}I-iodohydroxybenzylpindolol (IHYP)[1-3]. These studies have increased our understanding of the first step in the activation of adenylate cyclase by catecholamines, but have provided little insight into how binding effects an increase in enzyme activity. It is likely that agonists induce a change in the conformation of the receptor and that this altered form of the receptor interacts, directly or indirectly, with the enzyme to cause activation. Thus, an agonist-induced increase in the apparent Stokes radius of the digitonin-solubilised β-adrenergic receptor has been reported[4] and it has been shown that agonists cause an increase in the sensitivity of the β-adrenergic receptor to *N*-ethylmaleimide[5]. These results are consistent with the idea that conformational changes occur, but they provide relatively little information about the molecular mechanisms involved.

Differential effects of agonists and antagonists on receptor conformation should be readily apparent in the thermodynamics of the binding reaction. In fact, agonist but not antagonist affinities for β-adrenergic receptors increase at lower temperatures[6,7]. There is also indirect physiological evidence that agonist affinities are higher at lower temperatures, whereas antagonist affinities are unaffected by changes in temperature[8-11]. We report here that the thermodynamics of agonist and antagonist interactions with the β-adrenergic receptor of turkey erythrocytes are substantially different. This difference apparently reflects specific agonist-induced changes in receptor conformation.

Effect of temperature on ligand binding to the β-adrenergic receptor

The turkey erythrocyte membrane is a widely used model for the β-adrenergic receptor/adenylate cyclase system[1,4-6]. It is a convenient system in which to examine the effects of temperature, as the association and dissociation of IHYP binding to turkey erythrocyte β-adrenergic receptors occur 6–10 times faster than with other β-adrenergic receptors[12]. Incubation times required to reach equilibrium are therefore much shorter in the turkey erythrocyte membrane. The effect of temperature on the inhibition of IHYP binding by (−)propranolol and (−)isoprenaline are shown in Fig. 1. The displacement curve of the agonist isoprenaline shifts to the left at lower temperatures, reflecting an increase in affinity, whereas there is little change in the apparent affinity of propranolol. A similar increase in the apparent affinity of isoprenaline with decreasing temperature was also observed in studies of isoprenaline-stimulated adenylate cyclase activity (Fig. 2).

The changes in affinity observed are not a reflection of changes in *p*H as the K_D values of propranolol and isoprenaline did not change significantly between *p*H 6.8 and 7.8. The changes were also not an artefact of the longer incubation time used at lower temperatures, as the affinity of the receptor for isoprenaline measured at 37 °C after 5 h at 1 °C was the same as its affinity determined after only the 37 °C incubation. The K_D for isoprenaline at 1 °C was also unchanged by prior incubation for 15 min at 37 °C. The observed changes in affinity are therefore reversible and apparently a function of temperature alone. Full agonists displayed the largest increases in affinity with a lowering of temperature whereas the affinities of antagonists were essentially unchanged (Table 1). The effect of temperature on partial agonists was less than that on full agonists.

Thermodynamic analysis of the temperature dependence of binding

The standard Gibbs free energy change (ΔG°) of binding (association) was calculated from the equation

$$\Delta G^\circ = -RT \ln K_A \tag{1}$$

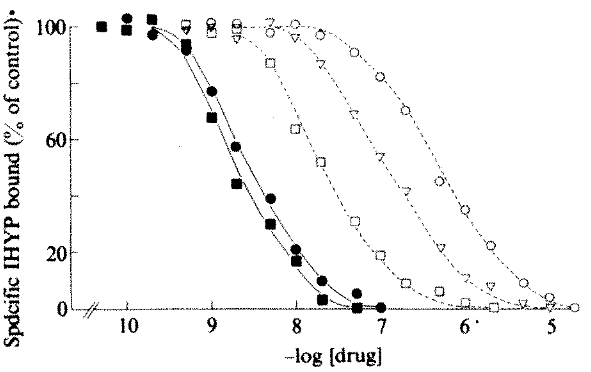

Fig. 1 Effect of temperature on the inhibition of specifically bound IHYP by (−)isoprenaline and (−)propranolol. Turkey erythrocyte membranes were prepared as described by Øye and Sutherland[33] and stored at −70 °C in 0.145 M NaCl containing 10 mM Tris-Cl (*p*H 7.4) and 1 mM EDTA at a protein concentration of 40 mg ml^{-1}. Immediately before use the membranes were thawed and diluted 100-fold in ice-cold isotonic saline containing 20 mM Tris-Cl (*p*H 7.5). Following centrifugation at 20,000*g* for 10 min at 4 °C, the membranes were resuspended in buffered saline to a protein concentration of 0.1 mg ml^{-1}. ^{125}I-iodohydroxybenzylpindolol (IHYP, 2.2 Ci μmol^{-1}) was prepared and purified as previously described[2,3]. Turkey erythrocyte membranes (10 μg protein) were incubated with IHYP (45,000–55,000 c.p.m.) and competing ligand ((−)isoprenaline: ○, ▽, □; (−)propranolol: ●, ■) in 0.25 ml of 0.09 M NaCl containing 1.1 mM ascorbic acid and 12 mM Tris-Cl (*p*H 7.2 at 24 °C) for 15 min at 37° (○, ●). 2.5 h at 10 °C (▽), and 5 h at 1 °C (□, ■). Bound IHYP was determined by filtration through glass fibre filters as previously described[34]. GTP (100 μM) had no effect on either agonist or antagonist binding at 1 °C or 37 °C. Specific binding was defined as the amount of IHYP bound in the absence of competing ligand minus the amount bound in the presence of 30 μM (−)isoprenaline. Specific binding routinely represented 90% of the total IHYP bound. Each point represents the mean of three experiments done in duplicate.

IC_{50} values were determined from Hill plots of the inhibition of specific IHYP binding at 37 °C and 1 °C (see Fig. 1). K_D values were calculated from the IC_{50} values by the method of Cheng and Prusoff[36] using the equation: $K_D = IC_{50}/(1 + L/K_L)$, where L is the concentration of free IHYP and K_L the equilibrium dissociation constant for IHYP determined by Scatchard analysis. Hill coefficients for the binding of ligands did not differ significantly from 1.0. K_L was 42 pM at 37 °C and 20 pM at 1 °C. The number of IHYP binding sites (B_{max}) was 372± 10 fmol per mg protein at 37 °C and 375±10 fmol per mg protein at 1 °C. The results shown are expressed as the mean±s.e.m. for 3–10 determinations done in duplicate.

where R is the gas constant (1.99 cal mol^{-1} deg^{-1}), T is the temperature in degrees Kelvin, and K_A is the equilibrium association constant ($1/K_D$). Changes in the standard Gibbs free energy reflect changes in enthalpy ($\Delta H°$) as well as changes in entropy ($\Delta S°$) as

$$\Delta G° = \Delta H° - T\Delta S° \qquad (2)$$

The enthalpy change of the binding reaction was determined using the integrated van't Hoff equation

$$\ln K_A = -\Delta H°/RT + \Delta S°/R \qquad (3)$$

The slope of a plot of $\ln K_A$ against $1/T$ is $-\Delta H°/R$. Once $\Delta G°$ and $\Delta H°$ had been determined, the standard entropy change of the reaction ($\Delta S°$) could be calculated from equation (2).

Van't Hoff plots for the binding reaction of five representative β-adrenergic ligands are shown in Fig. 3. The plots are linear over the temperature range studied, showing that the enthalpy change is independent of temperature. Both the enthalpy and the entropy changes of agonist binding are substantially different from those of the antagonists, despite the overlap in the changes in Gibbs free energy (Table 2). The most striking finding is that binding of full agonists results in a decrease in entropy. This decrease is thermodynamically unfavourable and it is only because of the large decreases in enthalpy that binding can occur. Thus, the binding of agonists is enthalpy driven, with marked net decreases in entropy, whereas the binding of antagonists seems to be almost completely entropy driven.

An excellent correlation was observed when the decreases in enthalpy and the efficacies of full and partial agonists were compared (Fig. 4*A*). Antagonists have zero efficacy and their binding is associated with an increase in entropy ranging from +13 to +42 entropy units (cal deg^{-1} mol^{-1}) (Fig. 4*B*). Full agonists had $\Delta S°$ values of less than −12 entropy units, and the binding of partial agonists had intermediate entropy values.

Molecular interpretations of the thermodynamics of binding

The entropy-driven binding of antagonists to the β-receptor is thermodynamically similar to many other protein-binding reactions where information transfer is not involved. Thus, for the interaction of ovalbumin with rabbit anti-ovalbumin antibody, $\Delta H° = 0$ kcal mol^{-1}, and $\Delta S° = +20$ entropy units (EU) (ref. 12), and for the binding of organic ions to bovine serum abumin, $\Delta H° = -2$ kcal mol^{-1} and $\Delta S° = +14.5$ to $+17.1$ EU (ref. 13). These reactions are probably driven by the increases in entropy which result when water molecules, ordered around the ligand and the binding site, are displaced[14]. In view of the relatively non-polar nature of the β-adrenergic receptor antagonists, it is likely that the binding is largely hydrophobic although other forces, including ionic interactions, hydrogen bonding and Van der Waals interactions, may also be involved. However, net enthalpy changes would not be expected because dissolution of energetically similar bonds with water would necessarily occur. In any case, these types of interaction are also entropy driven[15,16].

The thermodynamics of agonist–receptor interactions are substantially different from those of antagonist binding and other passive ligand–protein reactions. Note, however, that the thermodynamic parameters measured are net changes resulting from the interaction of a ligand and protein. These thermodynamic changes can also reflect induced conformational changes in the receptor or in adjoining molecules. As discussed above, binding reactions in general have a large positive entropy component. It is reasonable to suggest that occupation of the receptor by agonists also results in an increase in entropy. The net decrease in entropy observed on agonist binding may reflect

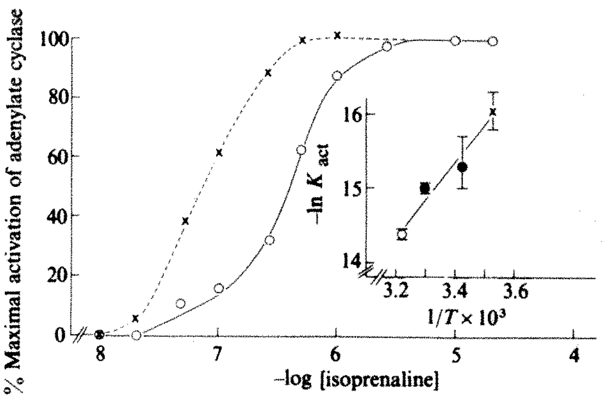

Fig. 2 Effect of temperature on the concentration dependence of (−)isoprenaline activation of adenylate cyclase. Adenylate cyclase activity was determined by measuring the conversion of [α-^{32}P]ATP to ^{32}P-labelled cyclic AMP and isolating the product by a modification of the method of Salomon *et al.*[35] as previously described[34]. The reaction was carried out in a final volume of 0.2 ml including turkey erythrocyte membranes (1–3 mg protein), 50 mM Tris-maleate (*p*H 7.5 at 24 °C), 5 mM cyclic AMP, 0.75 mM isobutylmethylxanthine, 5 mM $MgCl_2$, 0.5 mM EGTA, 0.25 mM ATP, 0.1 mg ml^{-1} creatine kinase, 10 mM creatine phosphate and 30 μM GTP. Reactions were run for 10 min at 37 °C (○) and for 60 min at 10 °C (×). Each point represents the mean of three experiments done in duplicate. Basal activities (in pmol cyclic AMP formed per min per mg protein) were: 0.55± 0.045 at 37 °C and 0.060±0.0024 at 10 °C. Maximal per cent stimulation by isoprenaline decreased with decreasing temperature. Isoprenaline stimulated adenylate cyclase 7.8-fold at 37 °C, 3.2-fold at 30 °C, 2.2-fold at 20 °C and 1.3-fold at 10 °C. Adenylate cyclase activity was linear with protein up to at least 4 mg. Inset: Van't Hoff plot (see text) of the dependence of K_{act} of (−)isoprenaline on temperature. K_{act} is the concentration of (−)isoprenaline which activates adenylate cyclase to 50% of maximum. Each point represents the mean of three experiments done in duplicate ± the s.e.m. The correlation coefficient (r^2) was 0.985, calculated by the method of least squares, and the enthalpy change of the reaction ($\Delta H°$) was −9.9 kcal mol^{-1}, calculated from the slope of the line ($-\Delta H°/R$; see text).

Assays were carried out in 0.09 M NaCl containing Tris-Cl (0.012 M, $pH = 6.8$). The changes in free energy, ($\Delta G°$), enthalpy ($\Delta H°$) and entropy ($\Delta S°$) of binding at 37 °C were calculated as described in the text.

an induced conformational change of the receptor protein or immediately surrounding membrane components. The net decrease in entropy would be the sum of the increase in entropy associated with binding and the larger decrease resulting from conformational changes. The large net decrease in enthalpy may primarily reflect the lower enthalpy of the particular conformational state of the receptor induced by the agonists.

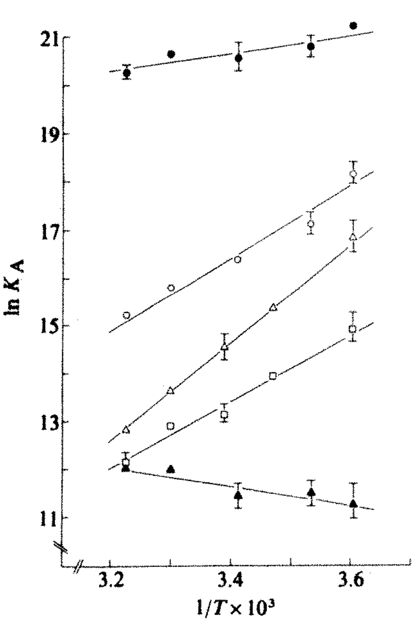

Fig. 3 Van't Hoff plots of the dependence of K_A on temperature. The data shown are for (−)propranolol (●), (−)isoprenaline (○), (−)noradrenaline (△), (−)adrenaline (□) and practolol (▲). K_A values were calculated from the equilibrium dissociation constants ($K_A = 1/K_D$) determined as described in Table 1. Each point represents the mean of 3–10 determinations done in duplicate ± the s.e.m. The s.e.m. of points with no error bars indicated were less than the size of the symbols. The dissociation constants for IHYP (in pM) were: 42 (37 °C), 33 (30 °C), 27 (24 °C), 23 (20 °C), 23 (15 °C), 22 (10 °C) and 20 (1 °C). The density of binding sites did not vary with temperature. The slope of the line is equal to $-\Delta H°/R$ (see text).

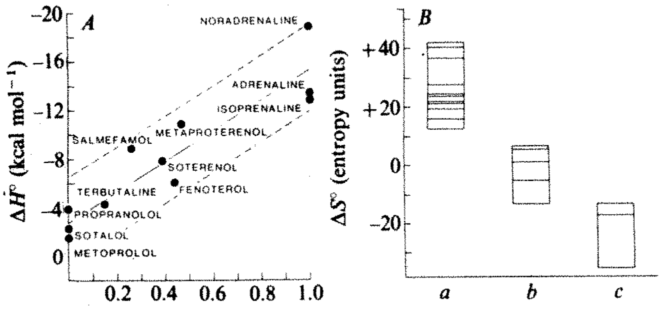

Fig. 4 Relationship between the enthalpy and entropy of binding and efficacy. *A*, The changes in enthalpy for the binding of ligands are plotted as a function of their efficacy. Efficacy was measured as the maximal activation of adenylate cyclase at 37 °C and is expressed as activation relative to the maximal activation by 30 μM (−)isoprenaline. Only three representative antagonists are shown. The solid line represents a linear regression analysis of the data shown. The correlation coefficient is 0.916. The dashed lines show the range of the values observed. *B*, The changes in entropy for the binding of the ligands in Table 2 are plotted as a function of antagonist (*a*), partial agonist (*b*) and full agonist (*c*) properties. Each horizontal line represents a ligand. The average entropy change for each group is: antagonists, +25.7 ± 2.7 EU; partial agonists, −0.92 ± 3.57 EU; full agonists, −21.7 ± 6.19 EU; The mean values of antagonists, partial agonists and full agonists differed from one another ($P < 0.01$). A plot of $\Delta S°$ against efficacy (not shown) gave a correlation coefficient of 0.888.

A two-step model similar to that proposed for agonist interactions with the nicotinic receptor[16,17] may be useful for β-adrenergic receptors.

$$L + R \overset{1}{\rightleftharpoons} LR \overset{2}{\rightleftharpoons} LR' \tag{4}$$

In this model, L is the ligand, R the receptor and R' the agonist-induced state of the receptor protein. Antagonists would participate only in reaction 1, with little or no change in enthalpy and large increases in entropy. Agonists and antagonists may bind in reaction 1 with similar themodynamic components; however, because of structural differences agonists are able to induce a conformational change of the receptor to R'. This conversion, reaction 2, would have negative enthalpy and entropy components. A large decrease in enthalpy could compensate for an unfavourable decrease in entropy and give reaction 2 a net negative free energy change, allowing it to occur. The extent of conversion to the R' state, the receptor conformation which leads to activation of adenylate cyclase, would be reflected in the efficacy of the particular ligand. This is consistent with the observed correlation between efficacy and both $\Delta H°$ and $\Delta S°$.

General use for the thermodynamic approach

Although the turkey erythrocyte membrane preparation is widely used for the study of the β-adrenergic receptor/adenylate cyclase system, the pharmacological specificity of β-adrenergic receptors on these cells is different from that of mammalian β_1- or β_2-adrenergic receptors[12]; there is no effect of GTP on agonist binding[18], and 'desensitisation' does not occur[19]. Despite these differences, the results and interpretation discussed above may be generally applicable. Preliminary results have shown differences in the thermodynamics of agonist and antagonist binding to β-adrenergic receptors of rat cerebral cortex and heart similar to those reported here (unpublished results). There is also physiological evidence that β-adrenergic receptors in several tissues have higher affinities for agonists at lower temperatures than at more physiological temperatures[7–10,20–22].

Various treatments cause agonist-specific changes in β-adrenergic receptor affinity. As affinity is a function of changes in the enthalpy and entropy of binding, alterations in affinity will reflect changes in these components. Thus, thermodynamic analyses of the agonist-specific changes in affinity which have been reported following cell disruption[23,24] and membrane solubilisation[6,25] and treatment with guanine nucleotides[26,27] or divalent cations[28] may contribute to our understanding of the molecular mechanisms involved in these changes.

Finally, temperature-dependent changes in apparent affinity have also been observed for the α-adrenergic receptor[29], histamine receptor[30,31] and for the affinity of ^{3}H-flunitrazepam for benzodiazepine receptors[32]. Thus, thermodynamic analysis may be a generally useful tool for examining the molecular events involved in hormone–receptor interactions.

Chicken ovalbumin contains an internal signal sequence

Vishwanath R. Lingappa, Jaisri R. Lingappa & Günter Blobel
Laboratory of Cell Biology, The Rockefeller University, New York, New York 10021

Ovalbumin is shown to contain an internal rather than an amino-terminal signal sequence. This internal signal can be recovered in a tryptic fragment which comprises residues 229–276 of mature ovalbumin and contains a region of striking sequence homology to amino-terminal cleaved signals of two other oviduct secretory proteins. The isolated tryptic fragment is used as a probe to demonstrate that a signal receptor is present in membrane vesicles derived from the rough but not in those derived from the smooth endoplasmic reticulum.

THE information for translocation of polypeptides across membranes was proposed[1] to reside in a discrete portion of the polypeptide chain, termed the signal sequence. For many secretory proteins the signal has been shown to consist of a short-lived amino-terminal extension, 15–30 amino acid residues long[1], that is cleaved from the chain during its synthesis and translocation across the rough endoplasmic reticulum (RER) membrane. Although the primary structure of the signals for various secretory proteins differs, there is circumstantial evidence that they all share certain features in their secondary structure[1].

In addition to secretory proteins, certain integral membrane proteins have been shown to contain a signal sequence that is functionally equivalent to that of secretory proteins[2]. These data suggest the existence in the RER of only one polypeptide transport system (translocator) that mediates transfer across the membrane in response to a signal which is common to secretory and certain integral membrane proteins.

It has been anticipated that cleavage of the signal is not an obligatory step for translocation of proteins across the RER membrane[3]. Ovalbumin seemed to provide a first example as it was found to be synthesised without the typical transient signal sequence[4]. Moreover, data obtained from *in vitro* translocation and competition experiments[5] provided strong evidence for the existence in *de novo* synthesised ovalbumin of an uncleaved signal sequence that was functionally identical to the cleaved signals of other secretory proteins. Like its cleaved counterpart the uncleaved signal of ovalbumin is expressed only by nascent but not by the completed, presumably folded chain[5]. Consequently, it was reasoned[5] that mature and secreted ovalbumin should contain a 'latent' signal that might be uncovered after denaturation or limited splitting of the molecule. The data presented here demonstrate that this hypothesis was correct, and, surprisingly, that ovalbumin contains an internal rather than an amino-terminal signal sequence.

Detection of signal activity in mature ovalbumin

To determine signal activity we measured the extent to which ovalbumin or its fragments are able to inhibit competitively *in vitro* translocation of nascent bovine pre-prolactin into dog pancreas microsomal vesicles[5]. The assay system consists of a cell-free protein-synthesising system (in the present case, a nuclease-treated rabbit reticulocyte lysate[6]) programmed with bovine pituitary mRNA and supplemented with ribosome-stripped and nuclease-treated microsomal vesicles from dog pancreas[7]. In the absence of microsomal vesicles, translation of bovine pituitary mRNA yields a major product (Fig. 1*a*, lane 1), previously shown[8] to be pre-prolactin (bovine pre-prolactin is

0028–0836/79/370117—05$01.00

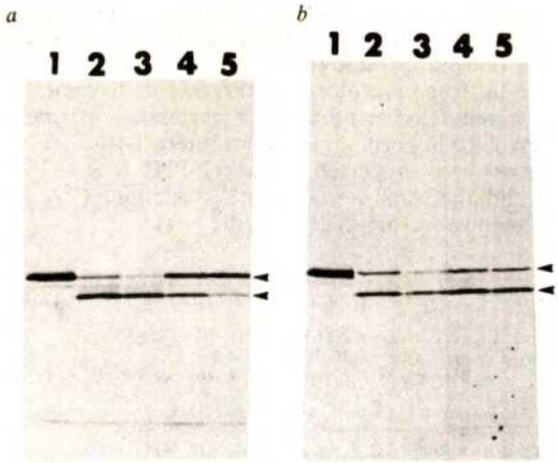

Fig. 1 Effect of unfractionated tryptic ovalbumin or serum albumin fragments on nascent pre-prolactin translocation. *a*, Bovine anterior pituitary mRNA (0.2 A_{260} units ml^{-1}) was translated in a nuclease-treated rabbit reticulocyte lysate containing 250 μCi ml^{-1} of ^{35}S-methionine (650 Ci $mmol^{-1}$) either in the absence (lane 1) or presence (lanes 2–5) of 1.0 A_{260} units ml^{-1} of nuclease-treated dog pancreas microsomal membranes[7]. Incubation mixtures also contained 8 mg ml^{-1} of native ovalbumin (lane 3, 8 mg ml^{-1}) of denatured ovalbumin (lane 4) or 0.5 mg ml^{-1} of tryptic ovalbumin fragments (lane 5). Preparation of denatured ovalbumin (OV_d) and tryptic ovalbumin fragments (OV_f) is described in Fig. 2 legend. Preparations of OV_d and OV_f were desalted[25] on Sephadex G-25 before being added to the incubation mixture. After incubation for 1 h at 25 °C, samples were prepared for polyacrylamide slab gel electrophoresis in SDS[8]. *a*, Shows an autoradiograph of the dried slab gel. Positions of pre-prolactin and prolactin are indicated by upper and lower arrowheads, respectively. *b*, As in *a*, except that equivalent concentrations of bovine serum albumin in native (lane 3), denatured (lane 4) or trypsin-digested (lane 5) forms was substituted for the corresponding ovalbumin forms.

prolactin plus an amino-terminal signal of 30 amino acid residues[8]). In the presence of microsomal membranes, however, prolactin is also synthesised (Fig. 1*a*, lane 2, and ref. 8), in amounts which depend on the concentration of microsomal vesicles: increasing concentrations of vesicles result in an increased synthesis of prolactin relative to pre-prolactin[8]. It has been demonstrated[8] that prolactin synthesis is the result of translation-coupled translocation of nascent pre-prolactin to the lumen of the microsomal vesicles where the signal is cleaved from the growing uncompleted chain. Following cleavage by signal peptidase on the luminal side of the microsomal vesicle, the nascent prolactin chain continues to grow and to be translocated until it is completed and entirely segregated within the lumen of the microsomal vesicle[8]. This *in vitro* synthesised and segregated prolactin is indistinguishable from mature prolactin[8]. Thus, because of their exclusive location—all pre-prolactin molecules outside the microsomal vesicles (sensitive to proteolysis) and all prolactin molecules inside the vesicles (resistant to proteolysis)—the ratio of prolactin to pre-prolactin is an accurate indicator for the extent of translocation[7,8].

As expected[5], mature native ovalbumin was ineffective as a competitive inhibitor for nascent pre-prolactin translocation, as the ratio of prolactin to pre-prolactin synthesised in the presence of mature native ovalbumin (Fig. 1*a*, lane 3) was comparable to that synthesised in its absence (Fig. 1*a*, lane 2). However, denatured ovalbumin was an inhibitor of nascent pre-prolactin translocation, significantly reducing the ratio of prolactin to pre-prolactin (Fig. 1*a*, lane 4). This inhibitory activity was dependent on the concentration of the added denatured ovalbumin and was lost on renaturation (data not shown).

Tryptic dissection of ovalbumin

The finding that mature ovalbumin molecules contain a latent signal activity that is uncovered on denaturation was of practical importance for our objective of undertaking a limited fragmentation of the ovalbumin molecule. Using this, we hoped to isolate an active fragment and localise the signal activity to a defined portion of the molecule. It would thus be possible to monitor rapidly the dissection process of the denatured ovalbumin molecule (by comparing its signal activity with that of the generated mixture of fragments) and thereby to establish conditions for its maximal fragmentation without a concomitant loss of signal activity. Such conditions were established by using trypsin as the dissecting tool. The tryptic ovalbumin fragments (see Fig. 2, lane 2) inhibited translocation of nascent pre-prolactin (Fig. 1*a*, lane 5).

Furthermore, neither mature (Fig. 1*b*, lane 3), denatured (lane 4) nor fragmented (lane 5) bovine serum albumin was able to inhibit translocations of nascent pre-prolactin. These results suggested that the inhibition of translocation observed with ovalbumin fragments was not a general property of secretory proteins or a nonspecific effect of hydrophobic peptides released from these globular proteins.

Purification and characterisation of an active ovalbumin fragment (OV_s)

The tryptic digestion mixture was subjected to conventional fractionation procedures described in detail in Fig. 2 legend.

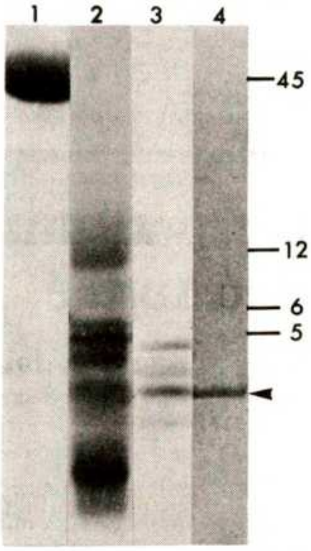

Fig. 2 Purification from trypsinised ovalbumin of a fragment with signal activity, monitored by polyacrylamide gel electrophoresis in SDS and 7 M urea. One gramme of chicken ovalbumin (Worthington) was dissolved in 20 ml of 0.25 M Tris-HCl, *p*H 7.5; 24 g of urea and 1.2 ml of 1.0 M dithiothreitol (DTT) were added and the solution volume was adjusted with water to 50 ml. After incubation at 37 °C for 1 h and at 100 °C for 15 min, the solution (containing 'denatured' ovalbumin (OV_d)) was diluted to 100 ml with water. 10 mg of trypsin–tosylphenylethylchloromethyl ketone (Worthington) were added every 6 h during 24-h incubation at 37 °C. Proteolysis was terminated by addition of phenylmethylsulphonyl fluoride (PMSF) to a final concentration of 2 mM. This solution of tryptic ovalbumin fragments was designated OV_f. Following isoelectric precipitation at *p*H 5.0 with glacial acetic acid, the precipitate was dissolved in 100 ml of 50 mM Tris-HCl, *p*H 7.5, 15 mM NaCl, 1 mM DTT and adjusted to *p*H 7.5 with 1.0 M NaOH. Ion exchange chromatography on DEAE-cellulose (25 ml bed volume) was carried out with 200 ml of a linear gradient of 15–750 mM NaCl containing 50 mM Tris-HCl, *p*H 7.5, and 1 mM DTT. Fractions (5 ml) were collected and assayed for signal activity, which was found to elute in a volume of ~40 ml with a peak at 400 mM NaCl. The material in this fraction was concentrated by another cycle of isoelectric precipitation at *p*H 5.0. The resulting pellet was dissolved in 5 ml of solution A (6 M urea, 50 mM Tris-HCl, *p*H 7.5, and 10 mM DTT) and applied to a column of Sephadex G-50 fine equilibrated with solution A. A major A_{280} peak eluted like a polypeptide of molecular weight (MW) ~8,000, in a total volume of 30 ml. This material is designated OV_{G50}. After dilution with water to 100 ml, an aliquot (1 ml) was subjected to polyacrylamide slab gel electrophoresis in 7 M urea (without SDS). Four distinct bands, similar in intensity and mobility to those shown in lane 3, were observed (data not shown). Individual bands were excised from the unstained gels and eluted by shaking, each into a volume of 5 ml of 5 mM Tris-HCl, *p*H 7.5. Following lyophilisation, each of the peptides was resuspended in 0.1 ml of 20 mM Tris-HCl, *p*H 7.5, and tested for signal activity. One of the peptides, designated as OV_s, was found to be active (see Fig. 3). Lane 1, 100 μg denatured ovalbumin (OV_d), note the absence of detectable degradation products; Lane 2, 20 μl of trypsin-digested ovalbumin (OV_f); Lane 3, 20 μl of OV_{G50}; Lane 4, 10 μl of OV_s. Numbers to the right of lane 4 refer to size ($\times 10^3$) of MW markers.

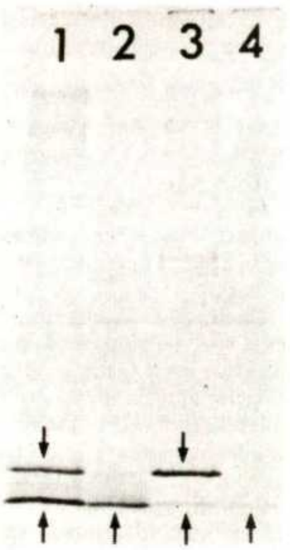

Fig. 3 Inhibition of nascent pre-prolactin translocation by a tryptic ovalbumin fragment (OV_s). Bovine pituitary mRNA was translated in the presence of microsomal membranes as described in Fig. 1 legend. OV_s (see lane 4 of Fig. 2) was either absent (lanes 1 and 2) or included (lanes 3 and 4) in the incubation mixture. Following termination of incubation for protein synthesis, aliquots (lanes 2 and 4) were subjected to post-translational proteolysis (incubation with 200 $\mu g\ ml^{-1}$ each of trypsin and chymotrypsin for 1 h at 0 °C in the presence of 10 mM $CaCl_2$). Proteolysis was terminated by the addition of Trasylol[2] and 1 mM PMSF followed by preparation for SDS-polyacrylamide slab gel electrophoresis. The figure shows an autoradiograph of the dried slab gel. Downward pointing arrow indicates pre-prolactin, upward pointing arrow indicates prolactin.

Table 1 Amino acid composition of OV_s compared with that of mature ovalbumin (OV_{1-385})[9] and selected tryptic ovalbumin fragments ($OV_{229-276}$ and OV_{1-46})

Purification of the signal activity was followed by assaying fractions for their inhibitory activity on nascent pre-prolactin translocation (data not shown) and by electrophoresis of active fractions in polyacrylamide gels containing urea and SDS (Fig. 2).

We succeeded in isolating a tryptic fragment which was pure by the criterion of its electrophoretic mobility as a single band (Fig. 2, lane 4) and which contained signal activity (Fig. 3); it was therefore designated OV_s. The presence of OV_s in the *in vitro* translocation system reduced the ratio of prolactin to pre-prolactin (compare lane 3 with lane 1 in Fig. 3). The increased amounts of pre-prolactin that were synthesised in the presence of OV_s were clearly extra-vesicular as they were digested by post-translational proteolysis (Fig. 3, lane 4). This result ruled out the possibility that OV_s acted as a competitive inhibitor not of nascent pre-prolactin translocation but of signal peptidase (in which case one would have detected pre-prolactin molecules within microsomal vesicles, protected from post-translational proteolysis).

OV_s was then subjected to amino acid analysis. When compared (Table 1) with the amino acid composition of ovalbumin, OV_s differed by an absence of Cys, Tyr and His residues, a relative abundance of Leu, Thr, Glu/Gln, Met, Ser and Ile residues, and a paucity of Ala residues. Furthermore, OV_s contained one Lys and one Arg residue, suggesting the presence of one trypsin site that had not been cleaved.

Based on its distinct amino acid composition, OV_s could be readily and unambiguously identified within the known sequence[9] of the ovalbumin molecule (Table 1). Thus, OV_s represents a limited tryptic fragment which contains 48 amino acid residues, beginning with Ile 229 and ending with Arg 276, and contains an uncleaved tryptic site represented by Lys 263. The relative resistance of this site to cleavage may be due to the presence of a glutamyl residue at position 262.

The localisation of signal activity in an internal rather than the amino-terminal region of mature ovalbumin was unexpected. The purification of OV_s from other tryptic fragments of ovalbumin was based on the premise that its ability to reduce the ratio of prolactin to pre-prolactin synthesised in an *in vitro* translocation system was due to competition (with the amino-terminal and cleavable signal of nascent pre-prolactin) for a site on the RER translocator; this premise needed to be substantiated to rule out an alternative mode or site of action of OV_s.

Homology of OV_s to signals of other chicken oviduct secretory proteins

Convincing evidence for the notion that OV_s contains the equivalent of the ovalbumin signal was obtained from a structural comparison (Fig. 4) of OV_s with the amino-terminal and cleaved signals of two other hen oviduct secretory proteins, ovomucoid and lysozyme[10,11]. There is clearly a significant degree of sequence homology. Particularly striking are two clusters of homology, each comprising three hydrophobic residues. There are also clusters of amino acid residues (indicated in bold face, Fig. 4) differing in their genetic code by a single base. Furthermore, the penultimate Gly residue of the two cleaved signals readily aligns with a Gly residue in OV_s. However, ovalbumin is not cleaved at this site. A possible explanation for this could be the absence of Cys or of Cys-Gly, located between the two hydrophobic homologous clusters in the case of the two cleaved signals but absent in OV_s (Fig. 4). It is likely[1,12] that this region constitutes the site of a β-turn or another secondary structural feature that is important for recognition by signal peptidase. Consistent with this reasoning is the recent demonstration[13] that a replacement of a glycyl residue by an aspartyl residue at position 14 of the 20-residue-long signal of lipoprotein in an *Escherichia coli* mutant results in the loss of the option to be cleaved but not of the ability to be translocated.

Fig. 4 Homology of OV_s to amino terminal cleaved signals of other chicken oviduct secretory proteins. The location of OV_s within the ovalbumin molecule was deduced from its distinctive amino acid composition (see Table 1) and the known[9] sequence of ovalbumin. Signal sequences[10,11] of pre-ovomucoid (pre OVM) residues 7–24 and of pre-lysozyme (pre LYS) residues 1–18 were each aligned to maximise homology to ovalbumin residues 234–254 within OV_s. Homologous residues between OV_s and pre OVM or between OV_s and pre LYS are boxed. Residues involving a single base change are indicated in bold face. Cleavage site of pre OVM and pre LYS is after glycine and is aligned with Gly 251 of ovalbumin.

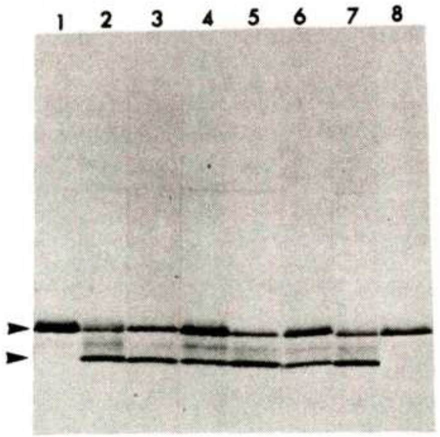

Fig. 5 RER-specific, competitive inhibition of nascent pre-prolactin translocation by $\mathrm{OV_s}$. Bovine pituitary RNA (0.2 A_{260} units ml^{-1}) was translated in the nuclease-treated reticulocyte lysate in the absence or presence of various membrane fractions and $\mathrm{OV_s}$. Membrane fractions were derived either from isolated rough or smooth microsomes (both from dog pancreas)[26] after removal of ribosomes and nuclease treatment[7] and are referred to in the text as RER or SER, respectively. Numbers refer to concentration in A_{260} units ml^{-1} (RER) or A_{280} units ml^{-1} (SER or $\mathrm{OV_s}$). Lane 1, neither membranes nor $\mathrm{OV_s}$ added. Lane 2, 1.0 RER, no $\mathrm{OV_s}$. Lane 3, 1.0 RER, 0.5 $\mathrm{OV_s}$. Lane 4, 1.0 RER, 1.0 $\mathrm{OV_s}$. Lane 5, 2.0 RER, 1.0 $\mathrm{OV_s}$. Lane 6, 1.0 RER, 1.0 SER, 1.0 $\mathrm{OV_s}$. Lane 7, 1.0 RER, 1.0 SER, no $\mathrm{OV_s}$. Lane 8, 1.0 SER, no RER, no $\mathrm{OV_s}$. Upper and lower arrowheads are as in Fig. 1.

Mode and site of action of $\mathrm{OV_s}$

The structural homology of $\mathrm{OV_s}$ with the signals of lysozyme and ovomucoid strongly suggested the existence of a common target represented by a signal 'receptor' domain in one of the hypothetical subunits that was proposed to participate in the assembly of the functional translocator[1,14].

The following experiments were carried out to establish $\mathrm{OV_s}$ as a valid probe for this receptor. The approach taken was to vary the concentration of some of the components of the *in vitro* translocation system while keeping that of others constant, and to measure the effect on nascent pre-prolactin translocation[5]. Some representative data of these experiments are shown in Fig. 5, and a systematic and quantitative analysis is summarised in Fig. 6.

First, we established that $\mathrm{OV_s}$ is indeed a competitive inhibitor. Increasing concentrations of $\mathrm{OV_s}$ (Fig. 5, lanes 3 and 4, Fig. 6*a*) resulted in an increasing inhibition of nascent pre-prolactin translocation, and increased concentrations of nascent pre-prolactin at a constant concentration of $\mathrm{OV_s}$ resulted in increased synthesis of prolactin (Fig. 6*c*). The competitive inhibition of $\mathrm{OV_s}$ could be offset (Fig. 5, lane 3 versus lane 5 and Fig. 6*b*) by increasing the concentration of RER (microsomal vesicles derived from the rough endoplasmic reticulum).

To demonstrate the existence of a specific target for $\mathrm{OV_s}$ we took advantage of our finding here that SER (smooth microsomal vesicles which probably include Golgi membranes) is unable to translocate nascent pre-prolactin (Fig. 5, lane 8) or to compete with RER for translocation (Fig. 6*a*); this strongly suggests that SER does not possess a signal receptor. SER was therefore chosen as a control to rule out the possibility that $\mathrm{OV_s}$ affected translocation not by its interaction with a specific signal receptor but rather, for example, by nonspecific interaction with membrane lipids. If this were the case one would expect that increasing concentrations of SER would titrate $\mathrm{OV_s}$, thereby offsetting the competitive inhibition of $\mathrm{OV_s}$ on nascent pre-prolactin translocation. The data shown in Fig. 6*b* demonstrate that this was not so.

Timing of ovalbumin translocation

One implication of our results is that translocation of ovalbumin across membranes would be initiated relatively late in the course of synthesis of the ovalbumin molecule. The precisely timed addition of membranes to a cell-free translation system synchronised with respect to chain elongation by the addition of an inhibitor of initiation[15,16], should provide information on the timing of ovalbumin translocation. In such a system an amino-terminal signal would be expected to require an early addition of microsomal membranes whereas an internal signal sequence would allow a greater length of chain to be synthesised before the growing chain would lose the capacity for functional interaction with microsomal membranes resulting in chain translocation. Our results (Fig. 7) comparing the timing of translocation of prolactin and ovalbumin are consistent with these expectations. The half-time of membrane addition (defined as the time at which translocation is reduced by 50%) was 2.0 min for prolactin and 5.5 min for ovalbumin. The half-time of chain completion (defined as the time at which 50% of the chains are completed in the synchronised system in the absence of membranes) was 5.0 min for prolactin and 8.5 min for ovalbumin (data not shown). Thus, assuming, a linear rate of synthesis, about 45 amino acid residues are incorporated per chain per min. As pre-prolactin and ovalbumin consist of 228 and 385 residues, respectively, it follows that the critical chain length after which translocation is abolished is about 90 residues for prolactin and about 250 residues for ovalbumin.

Comments

These results demonstrate that mature ovalbumin contains a latent signal sequence that can be uncovered after denaturation and can be isolated from the molecule as a tryptic fragment ($\mathrm{OV_s}$) comprising amino acid residues 229–276. A striking sequence homology to the amino-terminal cleaved signals of two other hen oviduct secretory proteins (lysozyme and ovomucoid) is evident in part of $\mathrm{OV_s}$ comprising residues 234–253. It is likely, therefore, that the signal activity resides in this portion of the ovalbumin molecule. Our demonstration here that an internal signal can compete with the amino-terminal cleaved signals strongly suggests that the two have a common target, presumably a receptor domain of a protein translocator.

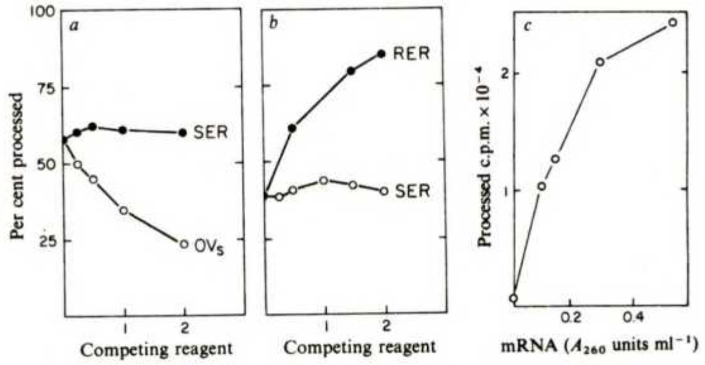

Fig. 6 Quantitative analysis of the effects of $\mathrm{OV_s}$ and SER on nascent pre-prolactin translocation. *a*, A constant amount of pituitary mRNA (0.2 A_{260} units ml^{-1}) was translated in the presence of a constant amount of RER (0.8 A_{260} units ml^{-1}) and increasing concentrations of either $\mathrm{OV_s}$ or SER. Unit concentration of competing reagent is 0.5 A_{280} units ml^{-1} for $\mathrm{OV_s}$ and 1.0 A_{280} units ml^{-1} for SER. Radioactivity in gel slices was determined as previously described[14]. The extent of translocation is expressed as percentage of radioactivity in the prolactin band over that in the pre-prolactin and prolactin bands. *b*, A constant amount of pituitary mRNA (0.2 A_{260} units ml^{-1}) was translated in the presence of a constant amount of $\mathrm{OV_s}$ (0.5 A_{280} ml^{-1}) and a minimum amount of RER (0.8 A_{260} units ml^{-1}). Increasing concentrations of either RER or SER were added as competing reagents in a unit concentration of 1.0 A_{280} units ml^{-1} for SER or 1.0 A_{260} units ml^{-1} for RER. *c*, Increasing concentrations of pituitary mRNA were translated in the presence of a constant amount of $\mathrm{OV_s}$ (1.0 A_{280} units ml^{-1}) and of RER (1.0 A_{260} ml^{-1}). The radioactivity in prolactin is shown as absolute c.p.m.

The existence of an internal signal sequence for the initiation of chain translocation has been previously postulated to explain the insertion into the RER of a viral integral membrane protein[17]. In this case, however, it was proposed[17] that the internal signal might be cleaved by signal peptidase, ultimately yielding two integral membrane proteins. The presence in ovalbumin of an uncleaved internal signal poses the intriguing problem of how nascent ovalbumin is actually threaded through the membrane. One possibility is translocation in the form of a loop, with the signal at its leading edge, in such a way that both the left (amino-terminal) and the right (carboxyl-terminal) wings of the molecule are translocated simultaneously, as the right wing of the molecule is being completed. Other conceivable mechanisms are cotranslational translocation primarily of the right wing followed by post-translational translocation of all or the remainder of the left wing of the molecule.

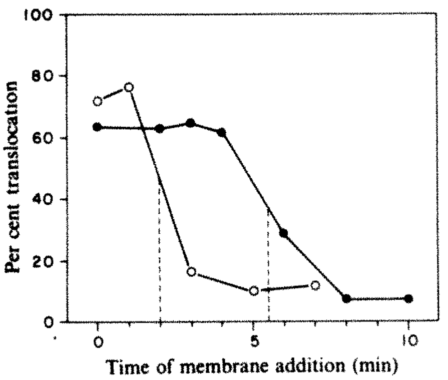

Fig. 7 Timing of translocation of prolactin and ovalbumin in a synchronised cell-free translation system. Protein synthesis was initiated in the reticulocyte lysate system. After 1 min of incubation, initiation of new chains was inihibited by the addition of 1.0 mM pactamycin[15]. At various times indicated on the ordinate, microsomal membranes (5.0 A_{260} units ml^{-1}) were added to aliquots of the translation mixture and protein synthesis allowed to proceed to completion. ^{35}S-Methionine-labelled translation products were analysed by SDS-polyacrylamide slab gel electrophoresis and radioactivity in individual bands was determined. Per cent translocation was expressed as either (○) per cent processed prolactin (PL/PL + prePL) or (●) per cent glycosylated ovalbumin ($\text{OV}_1/\text{OV}_1+\text{OV}_0$), as previously described[5].

Extrapolation of such considerations to the problem of how the polypeptide chains of integral membrane proteins (IMPs) achieve their often complex orientation with respect to the lipid bilayer offers interesting theoretical solutions. To define the relationship of the polypeptide chain with the lipid bilayer, IMPs can be classified[1] as monotopic (containing hydrophilic domain(s) exposed on only one side of the lipid bilayer) or bi- and polytopic (containing two or multiple hydrophilic domains exposed on both sides of the lipid bilayer). Two examples of bitopic IMPs have been shown[2,18] to be inserted into the membrane through an amino-terminal cleaved signal sequence that is functionally equivalent to that of nascent secretory proteins. To abrogate complete translocation of the nascent chain, the existence of a 'stop transfer' sequence has been postulated[2,19]. The combination of a cleaved amino-terminal signal and a stop transfer sequence further down the polypeptide chain would result in a bitopic orientation with the amino-terminal portion of the chain translocated and the carboxy-terminal portion untranslocated which, in fact, has been shown in these two cases[2,18]). Bi- or polytopic orientations could be achieved by an internal uncleaved signal sequence combined with a stop sequence. A stop on the right wing (see above) could result in a polytopic orientation whereby only an internal portion of the molecule is translocated, leaving substantial portions of both wings (containing amino and carboxy terminus) untranslocated. A stop on the left wing could result in a completely translocated right wing and an untranslocated left wing, leaving the amino-terminal portion of the molecule untranslocated. More complex polytopic orientations could be achieved by alternating multiple signal and stop sequences[17].

It is interesting that the last of the seven intervening sequences in the ovalbumin gene[20] is located between residues 254 and 255, that is, near the eliminated signal peptidase site. An intervening sequence near the signal peptidase site is also present in the gene for the light chain of IgG[21]. Thus, signal sequences and also stop transfer sequences could have evolved as a result of gene amplification and recombination[1].

The isolation of an internal signal is clearly of practical importance. OV_s has already been used here as a probe to demonstrate that its target is located in the rough and not the smooth endoplasmic reticulum. Experiments are in progress to study in detail the interaction of OV_s with the RER, in the hope that it can be used as an affinity ligand for the purification of its target.

Finally, the demonstration here of an internal uncleaved signal sequence with the same target in the RER as the amino-terminal cleaved signals, is relevant to currently used nomenclature. Retrospectively, it turns out that the term 'signal' was a more accurate choice[3] than designations such as leader sequence, pre-sequence or extra piece, all of which have structural implications such as amino-terminal location and/or cleavage. Thus, we propose that the term signal sequence be reserved to define a segment of the polypeptide chain, cleaved or uncleaved, which triggers protein translocation across a cellular membrane by virtue of its interaction with a specific translocator. Although it seems that a single translocator exists for the co-translational transfer of secretory and membrane proteins across the membrane of the RER, recent evidence indicates[22-24] that eukaryotic cells also contain several other specific translocators, localised to other distinct cellular membranes, for the recognition of structurally unique signals for the post-translational import of proteins from the cytosol into organelles.

This work was supported by grant CA-12413 from the NCI and grant NP-268 of the ACS. We thank Drs John Hemperly and Bruce Cunningham for carrying out amino acid analysis of OV_s.

Insulin isolated from the pancreas of a diabetic patient with fasting hyperinsulinaemia showed decreased activity in binding to cell membrane insulin receptors and in stimulating cellular 2-deoxyglucose transport and glucose oxidation. Chemical studies suggest that the isolated hormone is a mixture of normal insulin and an abnormal variant which contains a leucine for phenylalanine substitution at position 24 or 25 of the insulin B-chain.

INSULIN RESISTANCE, a clinical syndrome identified by an individual's failure to respond normally to endogenously secreted and exogenously administered insulin, can lead to severe diabetes even when plasma levels of the hormone are elevated. In many patients, this 'resistance' is due to a target cell abnormality or to the presence of circulating insulin antagonists[1]. We and others have described conditions in which cellular defects involve decreased numbers of membrane-associated insulin receptors in peripheral tissues[2] or decreased cellular responsiveness at a step subsequent to hormone–receptor interaction[3]. Circulating antagonists which lead to insulin resistance include anti-insulin antibodies[4], anti-insulin-receptor antibodies[5,6] and counter-regulatory hormones at high levels[1,7]. Patients exhibiting elevated plasma ratios of proinsulin to insulin[8] may also seem to be insulin resistant, but in these individuals the peripheral concentration of the 5,800-molecular weight hormone is lower than indicated by direct radioimmunoassay, and the patients actually respond normally to their plasma concentrations of free insulin.

We recently identified a patient (R.C.) with diabetes and hyperinsulinaemia whose disease did not seem to fit any of the above descriptions. Our findings, which will be described in detail elsewhere, showed that (1) the patient exhibited a fasting plasma glucose level of >200 mg dl^{-1} (normal, 80–120 mg dl^{-1}) and a fasting, plasma insulin level of 70–120 μunits ml^{-1} (normal, 5–24 μunits ml^{-1}); (2) the ratio of proinsulin to insulin in the patient's plasma was normal; (3) the patient's plasma did not contain anti-insulin or anti-insulin-receptor antibodies, nor elevated concentrations of insulin antagonists such as growth hormone, glucagon or cortisol; (4) the patient responded to exogenously administered insulin in a normal manner; (5) monocytes isolated from the patient's blood contained normal numbers of insulin receptors; (6) insulin isolated from the patient's plasma by immunoaffinity chromatography had a decreased ability to bind to both cultured IM-9 lymphocytes and rat adipocytes; (7) the plasma insulin had lower than normal activity in stimulating glucose uptake and oxidation in rat adipocytes. Although the possibility of a detrimental modification of the patient's insulin by a plasma factor could not be excluded, we considered it most likely that the patient secreted an abnormal insulin, the structure of which had been modified by genetic mutation. During exploratory surgery for the examination of an abdominal mass with pancreatic involvement, a portion of the patient's pancreas was removed for histological study. The portion remaining after completion of the pathological examination was made available to us for biochemical analysis. This report describes the isolation and characterisation of the patient's pancreatic insulin.

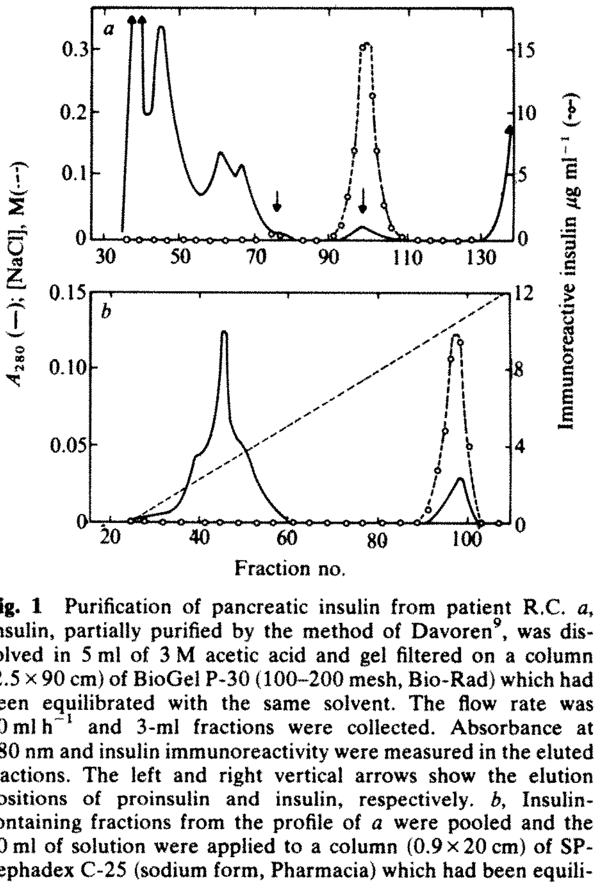

Fig. 1 Purification of pancreatic insulin from patient R.C. *a*, Insulin, partially purified by the method of Davoren[9], was dissolved in 5 ml of 3 M acetic acid and gel filtered on a column (2.5 × 90 cm) of BioGel P-30 (100–200 mesh, Bio-Rad) which had been equilibrated with the same solvent. The flow rate was 20 ml h^{-1} and 3-ml fractions were collected. Absorbance at 280 nm and insulin immunoreactivity were measured in the eluted fractions. The left and right vertical arrows show the elution positions of proinsulin and insulin, respectively. *b*, Insulin-containing fractions from the profile of *a* were pooled and the 30 ml of solution were applied to a column (0.9 × 20 cm) of SP-Sephadex C-25 (sodium form, Pharmacia) which had been equilibrated with 3 M acetic acid. The column was washed with 50 ml of the solvent and a linear gradient of NaCl dissolved in 3 M acetic acid (0–0.25 M, 200 ml of each) was applied to the column at a flow rate of 30 ml h^{-1}. Fractions containing 3 ml were collected and absorbance at 280 nm and insulin immunoreactivity were measured.

Isolation of insulin

A 3.1-g specimen of pancreas from patient R.C. was homogenised in acidified ethanol and the insulin partially purified by

0028-0836/79/370122—04$01.00

Table 1 Amino acid composition of isolated insulin and insulin fragments

Peptides were hydrolysed under vacuum at 110 °C for 20 h in 6 M HCl containing a small amount of phenol. Analyses were carried out on a Durrum amino acid analyser. Relative amino acid concentrations were converted to nearest integer values to obtain the compositions reported in columns labelled 'Found'. Columns labelled 'Theory' show the known compositions of the normal human peptides. Cysteine content was not determined (ND).

the method of Davoren[9]. Material obtained by ether–alcohol precipitation was dissolved in 3M acetic acid and the resulting solution was gel-filtered on BioGel P-30 to yield the profile shown in Fig. 1*a*. Our finding that approximately 95% of the insulin-like immunoreactivity appeared as a single component having the size of native insulin (fractions 91–109) indicates a normal ratio of pancreatic proinsulin to insulin. To avoid additional methods of purification either requiring large amounts of material, such as crystallisation, or resulting in low yields, such as paper electrophoresis, we developed the specialised use of cation exchange chromatography for the final purification of the hormone. Fractions 94–105 from the profile of Fig. 1*a* were pooled and applied without concentration to a column of SP-Sephadex which had been equilibrated with 3M acetic acid. Application of a gradient of NaCl to the column resulted in the absorbance and immunoreactivity profiles shown in Fig. 1*b*. The peak of immunoreactive insulin was well separated from earlier eluting material which included the proinsulin C-peptide as well as other contaminating peptides. The yield of insulin, after pooling and desalting fractions 92–101, was approximately 50 nmol as measured either by absorbance at 275 nm or by colorimetric methods[10]. This value, which is equivalent to a yield of 98 mg per kg of tissue, represents the expected content of the hormone in pancreatic tissue[11].

To standardise the preparation further, identical amounts of the isolated insulin and monocomponent porcine insulin, as determined by the Lowry protein assay[10], were diluted in parallel and examined by radioimmunoassay[12]. As shown in Fig. 2, the immunometric potencies of the patient's insulin and porcine insulin were indistinguishable over a wide range of concentration. This result indicates the high degree of purity of the isolated insulin and validates the use of our radioimmunoassay in its measurement. Experiments not illustrated here also showed that the mobility of the patient insulin during polyacrylamide gel electrophoresis at *p*H 8.7 (ref. 13) or *p*H 4.5 (ref. 14) was indistinguishable from that of normal human insulin. As both gel systems are capable of resolving peptides having single charge differences, we could disregard the possibility that the preparation was contaminated by desamido- or arginyl-insulin, or that charged residues within the patient insulin had been modified. Glucagon was not detectable by sensitive radioimmunoassay in the final preparation.

Biological activity

The biological effectiveness of the pancreatic insulin from patient R.C. was compared with that of monocomponent porcine insulin on the basis of immunometric equivalency. This comparison is validated by the results of Fig. 2 and by our previous studies which have shown that porcine insulin and normal human insulin are equipotent when tested in any of the receptor-binding or biological assay systems used[3,25]. As illustrated in the experiments of Fig. 3, the patient insulin did not compete as well as normal insulin did for the binding of ^{125}I-labelled porcine insulin to cultured, human IM-9 lymphocytes or to isolated rat adipocytes. The shapes of the respective inhibition curves, however, were similar to those obtained using normal insulin. The decreased effectiveness of the patient insulin in these systems was confirmed on many occasions for the hormone isolated from both pancreas and plasma. Average potencies were 46 ± 8% of normal (average ± s.d.) for binding to IM-9 lymphocytes ($n = 9$) and 51 ± 8% of normal for binding to rat adipocytes ($n = 7$). Further experiments were designed to assess the biological activity of the insulin from patient R.C. Figure 4 shows that, whether activity was measured by stimulation of 2-deoxyglucose transport or by stimulation of ^{14}C-1-glucose oxidation, the patient insulin showed greatly decreased biological activity. Its potency, assessed by estimating that concentration causing half-maximal stimulation, was only 11 ± 5% ($n = 8$) and 12 ± 5% ($n = 14$) of normal in the two respective systems. Nevertheless, at high concentrations (10–50 ng ml^{-1}) the patient insulin was fully effective at stimulating these cellular processes. This decreased biological activity, as well as the decreased ability of the insulin to bind to membrane receptors, suggested that the pancreatic insulin from patient R.C. was structurally different from normal human insulin.

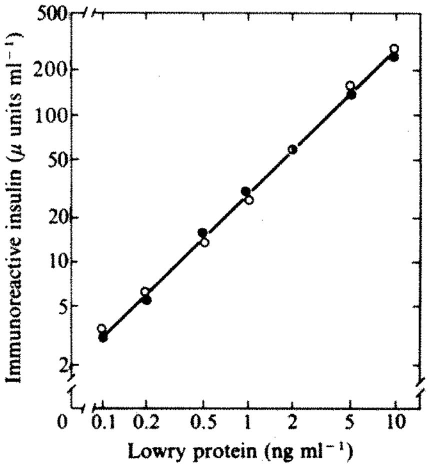

Fig. 2 Immunoreactive potency of the patient insulin. The protein concentration of the solution of patient insulin was determined by the method of Lowry[10] using a standard curve derived from porcine insulin. Amounts of the patient insulin and monocomponent porcine insulin corresponding to 1 μg of protein were diluted in parallel to give the concentrations shown on the abscissa. Aliquots (1 ml) of each solution were then subjected to the radioimmunoassay in standard conditions[12]. Averages of duplicate immunoreactivity determinations for the patient insulin (○) and monocomponent porcine insulin (●) are shown.

Chemical characterisation

Treatment of the purified patient insulin with 1-dimethylaminonaphthalene-5-sulphonyl chloride followed by subsequent analysis[19] led to identification of glycine and phenylalanine as the NH_2-terminal residues of the peptide. Amino acid analysis was carried out on the isolated peptide to probe a possible structural alteration in the patient insulin. As shown in the first column of Table 1, the compositional values obtained are very close to those expected for human insulin, with the exceptions that the content of leucine was high and that of phenylalanine low. The sources of the slightly elevated values for histidine and lysine are not known, but the presence of these residues in the patient insulin could be excluded because the peptide showed the expected electrophoretic mobilities during polyacrylamide gel electrophoresis. As NH_2-terminal analysis showed both phenylalanine and glycine, we could assign one residue of phenylalanine to position 1 of the insulin B-chain. In the simplest case, any decrease in phenylalanine content must then result from an amino acid substitution at position B_{24} or B_{25}. Fortuitously, these residues occur in the COOH-terminal octapeptide of the insulin B-chain, a region which is easily excised by proteolytic digestion.

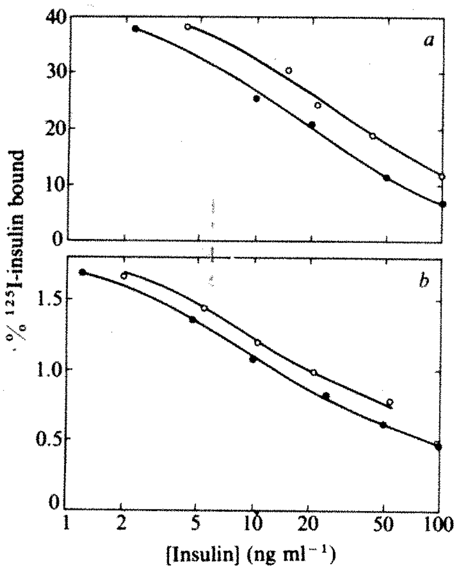

Fig. 3 Competition for the binding of ^{125}I-labelled porcine insulin to plasma membrane receptors by the patient insulin. *a*, Binding of insulin to cultured, human IM-9 lymphocytes; *b*, binding of insulin to isolated, rat adipocytes. Methods for the preparation of cells and for the binding studies using lymphocytes[16] and adipocytes[15,17,18] have been described. In each case, the potency of the patient insulin (○) was compared with that of monocomponent porcine insulin (●) at the concentrations shown.

The patient insulin (100 μg) was incubated at 30 °C for 3 h with 10 μg of tosylphenylalanine chloromethylketone-treated trypsin in 0.2 ml of 0.1 M *N*-ethylmorpholine brought to *p*H 8 with acetic acid. The resulting desoctapeptide insulin (lacking residues B_{23-30}), heptapeptide (containing residues B_{23-29}), and threonine (residue B_{30}) were separated by paper electrophoresis in the above *N*-ethylmorpholine buffer; peptides were subsequently eluted in 50% acetic acid. Amino acid analysis of the desoctapeptide insulin demonstrated, as expected, the presence of a single residue of phenylalanine (Table 1, column 3). The amino acid composition of the heptapeptide B_{23-29} (Table 1, column 5) shows values consistent with theory for glycine, tyrosine, threonine, proline and lysine. The peptide was deficient, however, by the equivalent of 0.6 residues of phenylalanine and contained the equivalent of 0.6 residues of leucine, an amino acid not expected from theory, nor found when we applied identical procedures to the preparation and analysis of the heptapeptide from porcine insulin. These results localise the leucine for phenylalanine substitution, which was suggested by the amino acid composition of the intact insulin, to the COOH-terminal octapeptide of the B-chain. Our finding of less than a full residue of leucine in the heptapeptide, however, suggests a limited degree of microheterogeneity in the isolated hormone. As we wished to conserve the remaining small amount of insulin for use as a structural probe of the insulin receptor, and as the amino acid substitution could only have occurred at one or the other of the two adjacent phenylalanine residues of the heptapeptide (B_{24} or B_{25}), we did not attempt to place the substitution in sequence.

Discussion

Our results show that the pancreatic insulin isolated from a patient who was resistant to endogenous insulin, but who responded normally to exogenous insulin, had a substantially lower than normal biological activity. These findings extend our observation that insulin isolated from the patient's plasma was of low potency and identify the defect in the hormone as occurring before its secretion. The leucine for phenylalanine substitution, which we localised in the COOH-terminal region of the B-chain of the patient insulin, represents a single base change which might have occurred by either of two point mutations, regardless of which of the phenylalanine codons were present in the gene sequence. This statistically favourable mutation undoubtedly results in the decreased biological effectiveness associated with the isolated insulin. Our finding of lower than integral values for the content of phenylalanine and leucine in the patient insulin, and a preliminary observation that the ^{125}I-labelled patient insulin is divisible into two components based on ability to bind to membrane receptors, suggest that the isolated hormone consists of normal human insulin and the mutant insulin in the approximate ratio 40:60. We consider that this mixture probably represents the products of the nearly co-dominant expression of two allelic genes in the heterozygous state; it is thus likely that identical maternal and paternal insulin genes are expressed simultaneously in normal individuals. In the absence of a more complete genetic analysis, however, we cannot exclude the possibility that the microheterogeneity, in

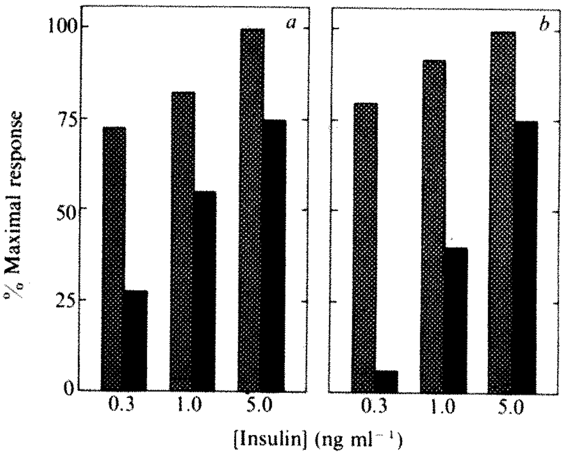

Fig. 4 Biological activity of the patient insulin. *a*, Stimulation of ^{14}C-2-deoxyglucose transport into isolated, rat adipocytes; *b*, stimulation of ^{14}C-glucose oxidation by isolated, rat adipocytes. Methods for the transport and glucose oxidation experiments have been described[12,15]. In each case, the potency of the patient insulin (solid bars) is compared with that of monocomponent porcine insulin (hatched bars) at the selected concentrations shown. Basal and maximally stimulated values for 2-deoxyglucose transport were 0.13 and 0.51 nmol per 2×10^5 cells per 3 min, respectively. Basal and maximally stimulated values for glucose oxidation were 3 and 61 nmol per 2×10^5 cells per h, respectively.

this selected case, results from the expression of two non-allelic genes, as is found for the two insulins of the rat[20,21].

Although we have not placed the proposed amino acid substitution in sequence, its localisation to position 24 or 25 of the insulin B-chain, as illustrated diagrammatically in Fig. 5, is particularly interesting. First, the B-chain sequence, Gly-Phe-Phe-Tyr, residues 23–26, has remained invariant during animal evolution, even when considering the hormones derived from the guinea pig[21] or the primitive hagfish[22]. No other sequence lacking cysteine residues and having comparable length seems to be as stable from an evolutionary point of view. Second, using various criteria, residues 23–26 of the COOH-terminal region of the B-chain have been placed in the active site of the hormone. Particularly important are the findings that the biological activity of modified insulins decreases progressively as from five to eight residues are removed from the COOH terminus of the B-chain[23] and that synthetic peptides containing residues B_{22-26} have low amounts of insulin-like activity[24]. The effects of replacing phenylalanine by leucine within this sequence seem to be quite specific, as this change has little effect on the general hydrophobic character of the region. Third, the COOH-terminal B-chain sequence containing residues 24–26 has been assigned to the negatively cooperative site for the interaction of the hormone with its receptor[25]. Fourth, this region of the B-chain has a crucial role in dimer formation within the zinc–insulin hexamer[26]. Note, however, that electron micrographs of islet tissue from patient R.C. revealed well defined crystalline inclusions typical of insulin-containing secretion granules. Other aspects of pancreatic and insular morphology were also unremarkable.

The low biological activity of the patient insulin (11–12% of normal), in comparison with its receptor binding activity (46–51% of normal), represents an unexpected result. Similar findings have been reported for the action and binding of hagfish insulin in mammalian systems (ref. 27 and S. Emdin, personal communication), but these findings have been questioned[28]. Notwithstanding this discrepancy, our results might be explained by a multi-step mechanism of insulin action allowing a degree of dissociation between receptor binding and hormone action, or by an antagonism of the action of the normal insulin by the abnormal variant in the preparation used. Because the apparent binding potency of the patient insulin corresponds well with that expected from the amount of normal insulin present in the mixture, the latter possibility seems the more likely. The very low biological activity of the patient insulin further suggests that this proposed antagonism occurs in a multiplicative way; that is, one molecule of the variant apparently inhibits the action of several molecules of normal insulin. This model would have important implications in the study of the mechanism of insulin action.

The relationship between the insulin variant and our patient's diabetes is important. Considerations of spare insulin receptors might have predicted a physiological compensation by the secretion of additional amounts of the hormone. The antagonistic behaviour of the variant in the secreted hormonal mixture suggests, however, that such compensation might not have been possible *in vivo*. It is likely that the increased ratio of active insulin to the variant produced by the insulin tolerance test was crucial in correcting the patient's glucose intolerance in our clinical studies. Our description of an abnormal insulin suggests the usefulness of the cataloguing of diabetes in hyperinsulinaemic states in which the disease can be ascribed to (1) a mutation in the structural gene for (prepro)insulin, (2) incomplete conversion of proinsulin to insulin, (3) circulating antagonists to insulin, (4) defects in the insulin receptor site, and (5) defects in target cell responsiveness at a site distal to hormone–receptor binding. Identification of the biochemical abnormality in any individual thus requires a comprehensive evaluation of these various possibilities. We are now examining plasma insulin from other patients whose insulin resistance mimics that of patient R.C. Use of these insulins as naturally occurring analogues is likely to provide further insight into the structural requirements for the binding of insulin to its receptor and for its activation of cellular processes.

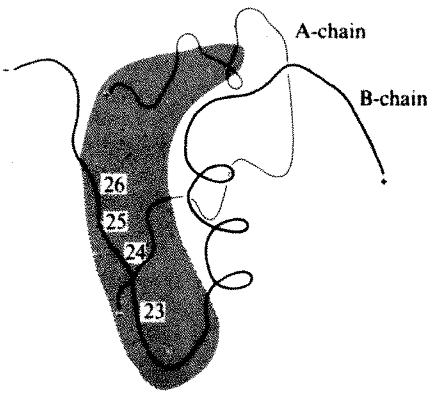

Fig. 5 Diagrammatic representation of the structure of insulin. The simplified drawing is derived from the crystallographic and other studies of Blundell *et al.*[29]. The biologically important, active site is indicated by hatching, and the positions of the invariant residues B_{23-26} (Gly-Phe-Phe-Tyr) are shown.

We thank Dr R. Heinrikson for assistance in the amino acid analyses. The high-latitude EUV source HD192273 as a low-mass binary

Harry L. Shipman & Gary A. Wegner

Physics Department, University of Delaware, Newark, Delaware 19711

The B star HD192273 was tentatively identified[1] as an extreme-ultraviolet (EUV) source. Photometry[2] and photographic spectra of this star show that the optical and EUV fluxes fit a model with $T_e = 27{,}000$ K and log $g = 4.8$, values reasonably close to those of a normal B2 V star. However, if HD 192273 is such a normal main-sequence star, its distance D is ~4 kpc, difficult to reconcile with the low line-of-sight column density ($<10^{18}$ cm^{-2} over the 4-kpc path), the low radial velocity (-24 km s^{-1}), and the high distance (~2 kpc) out of the galactic plane. Instead, we suggest that this object is an analogue of HZ22, an evolved, low-mass component of a binary[3], where the spectroscopic log g is consistent with a relatively small radius (0.1–1 $R_\odot$ and a small distance D of 100–200 pc. Such a suggestion can explain both the low H I column density and the small radial velocity.

Trimble's[4] calculations of the evolution of evolved binary components like HZ22 show that following mass exchange, stars with helium cores and thin hydrogen envelopes spend appreciable times (10^3–10^6 yr, with longer lifetimes at lower masses) near the He main sequence. Using Wegner's spectroscopic value of log $g = 4.8$,

$$\log R/R_\odot = -0.7 + 0.5 \log (M/0.1M_\odot) \tag{1}$$

Trimble's lowest-mass models with $M/M_\odot = 0.26$ fall reasonably close to the radius specified by equation (1). The spectroscopic temperature of 27,000 K specifies the monochromatic Eddington flux as 2.52×10^{-4} erg cm^{-2} Hz^{-1} (ref. 5). Adopting the relation between flux, magnitude, radius, and distance described in ref. 6, using equation (1) and taking $V = 8.827$, we obtain:

$$D = 80(M/0.1M_\odot)^{1/2} \text{ pc} \tag{2}$$

The precise value of D depends more on M and less on T and log g. We suggest that M is a few tenths of a solar mass giving $D = 100$–200 pc.

Wegner[2] derived a maximum H I column density of 5×10^{17} cm^{-2} from fitting a $T_e = 28{,}630$ K model to the observations of the EUV flux. Some exploration of the sensitivity of the upper limit to assumptions regarding T_e and log g is warranted, because the dependence of the EUV flux on T_e is quite steep, (the flux at 600 Å increases by a factor of 100 between $T_e = 27{,}500$ K and $T_e = 32{,}500$ K in Mihalas' models)[7]. A maximal temperature of 32,500 K, log $g = 4$, and a non-LTE model maximises the EUV flux at the stellar surface in a way consistent with the optical observations. Such a model gives $F(600\text{ Å})/F(5{,}500\text{ Å}) = 0.27$ at the star, which can be reduced to the observed value (at the Earth) of 0.0034 if the optical depth at 600Å to HD192273 is 2.

Such an optical depth corresponds to a column density of 10^{18} H I atoms cm^{-2} using the cross-sections of Cruddace *et al.*[8]. This limit is insensitive to the details of the analysis. No matter what kind of an EUV emitter this source is, the optical depth to it cannot be too high without making it invisible.

Is this interstellar column density reasonable, given current conceptions and observations of the interstellar medium? Consider two models: (1) HD192273 is a normal, main-sequence B star with $M_V = -4$ at a distance of 3.6 kpc (ref. 9) and (2) the present suggestion that it is a low-mass binary at a distance of 100–200 pc. Bohlin *et al.*[10] provides a survey of interstellar N(H I) based on observations of Lyα. Their Fig. 5 contains observations of stars far from the galactic plane, showing positive detections of N(H I) exceeding 10^{20} cm^{-2} for seven high-latitude stars with distances exceeding 100 pc. Were HD 192273 a normal B star, its distance of 3.6 kpc would place it far beyond all the stars observed by Bohlin *et al.* We therefore conclude that model (1) is inconsistent with the data from interstellar Lyα observations.

However, if HD192273 were much closer, the interstellar column density required is compatible with the observations of other EUV sources. The upper limit to the column density towards HD192273 is only slightly smaller than the values of the column density obtained for HZ43 [where $0.8 \times 10^{18} <$ N(H I) $< 2.5 \times 10^{18}$ (ref. 11)], and Feige 24 [where N(H I) can vary between 10^{18} and 5×10^{18} cm^{-2} (H.L.S., unpublished) or is less than 3×10^{18} (ref. 12).] The distances of HZ43 and Feige 24 are 60 pc (ref. 13) and 60–140 pc (ref. 14) respectively, comparable to the distance to HD192273 if it is a low-mass binary. Bohlin *et al.*[16] provide little information on such nearby objects, but the reasonably well established column densities towards HZ43, Feige 24, and the density towards HD192273 if model (2) is correct seem consistent with their observations, particularly considering that the neutral hydrogen is concentrated in a few clouds.

This interpretation of HD192273 is supported by two other pieces of information. Its spectroscopic log g, although uncertain, seems slightly high for a main-sequence B star. Furthermore, its low radial velocity would present problems were it 2 kpc from the galactic plane. Greenstein and Sargent[15] discuss a fairly large sample of similarly paradoxical high-latitude B stars. Their Table 4 provides an indication of the time required for stars with various radial velocities and at various heights z above the galactic plane to reach their present positions. FB180 and FB181, with z-distances of 1.6 and 1.9 kpc and $\rho'(z) = -31$ and -21 km s^{-1} respectively, are similar to HD192273 as a main-sequence B star with $z = 1.8$ kpc and $\rho' = -27$ km s^{-1}. (Here $\rho'(z)$ is the component of the radial velocity in the z-direction, corrected for solar motion.) Both FB180 and FB181 would take 4×10^7 yr to reach their present positions, and so we infer that a similar time scale applies to HD192273 if model (1) is correct. But as a main-sequence star, HD192273 has a lifetime of only 6×10^6 yr, and thus there is no obvious way that it could come to be where it is. However, if HD192273 is a low-mass binary component 100–200 pc away (model 2), the low radial velocity presents no problems.

This suggestion that HD192273 is a low-mass binary, combined with the spectroscopically confirmed binary nature of

0028–0836/79/370126—02$01.00

HZ22, prompts a speculation that many of the high-latitude O and B stars with low radial velocities and apparently large distances could be similar low-mass binaries at considerably smaller distances. This picture of HD192273 as a low-mass binary could be confirmed by a radial velocity study, although the absence of radial velocity variations would not rule out the present interpretation.

A limit to the X-ray luminosity of nearby normal galaxies

D. M. Worrall, F. E. Marshall & E. A. Boldt

Laboratory for High Energy Astrophysics, NASA/Goddard Space Flight Center, Greenbelt, Maryland 20771

The origin of the extragalactic diffuse X-ray background is not well understood. It is isotropic to the extent that a galactic origin can be excluded. Indeed, even a halo of radius as large as 12 kpc could provide no more than 3% of the flux[1]. The spectrum between 3 and 50 keV fits a 40-keV thermal bremsstrahlung form which is suggestive of emission from a hot intergalactic medium[2]. This or some other truly diffuse mechanism may be responsible. If, however, discrete sources play a major part, we require either strong evolution of an already recognised X-ray emitting class, such as quasars, or as we consider here, a hitherto elusive population of low luminosity emitter.

Without invoking evolution, the largest background contributions are thought to derive from Seyfert galaxies and clusters of galaxies. Based on estimated local densities, the total background cannot be accounted for[2,3]. Consistency with fluctuation measurements of the diffuse background is only achieved if members of the additional non-evolved class of source, which would be required to complete the background, are sufficiently numerous and hence of low luminosity. Compatibility requires a volume density $\gtrsim 8\times10^{-3}h^3$ Mpc^{-3} (ref. 3), where h is the present Hubble constant in units of 100 km s^{-1} Mpc^{-1}. The diffuse background between 2 and 10 keV has an emissivity $\sim4.7\times10^{39}h$ erg s^{-1} Mpc^{-3}, which places an upper limit of $\sim6\times10^{41}/h^2$ erg s^{-1} on the source luminosity. (We quote luminosities between 2 and 10 keV to ease comparison with other work. However, the source and diffuse background data used here are both from the HEAO A-2 experiment and comparison will be made over the entire energy range for which we have a response, that is 2–60 keV; with highest efficiency 3–20 keV.)

Such weak extragalactic sources do not present a high detection probability for non-imaging proportional counter experiments. The requirements for source detection with the A-2 detectors on the HEAO 1 spacecraft are discussed in ref. 4. There is dependence on ecliptic latitude and consequent exposure but a 5σ detection threshold is $\sim2\times10^{-11}$ erg cm^{-2} s^{-1} (2–10 keV) requiring, for example, a 10^{40} erg s^{-1} emitter to be within ~2 Mpc. To date the only catalogued galaxies $<10^{42}$ erg s^{-1} are SMC, LMC, M31, Cen A and M82. Of these, the latter two are radio galaxies but are, probably, atypical of their class in general. The others are classed as normal galaxies and their X-ray luminosity is compatible with that of our Galaxy, estimated, from the summed emissivity of known sources, to be $\sim2\times10^{39}$ erg s^{-1}. Taking M31 and the Galaxy as standards, normal galaxies are estimated to contribute only a few per cent of the diffuse background[3,5,6]. However, as the most numerous extragalactic object they merit further examination in the search for a class of low luminosity X-ray source.

We report here results of a test of the hypothesis that normal galaxies are on average more luminous than our Galaxy and M31 and therefore form a candidate class of numerous low luminosity emitters which may fulfill requirements for contributing substantially to the diffuse background. The imaging experiments on the Einstein Observatory will measure at energies below ~4 keV where low-energy absorption and soft sources will limit comparison with the 2–60 keV background. As noted above, the comparison between source and background fluxes are made over the HEAO A-2 experiment energy range. But, where 2–10-keV source luminosities are given, a constant multiplicative factor suitable for a 9-keV thermal bremsstrahlung spectrum has been used.

Data from the A-2 detectors on the HEAO 1 spacecraft[7] were investigated for emission from positions coincident with normal galaxies selected from the *Second Reference Catalogue of Bright Galaxies*[8]. Selection required a velocity <1,100 km s^{-1} (that is $D<20$ Mpc for $H_0=55$ km s^{-1} Mpc^{-1}). Positions contaminated by catalogued X-ray sources were excluded. Since only data from the 1.5° × 3° field of view detectors were used, a source free region 3° each side of the galaxy along the scan direction and 5° in the perpendicular direction was demanded. Where galaxies were clustered the closest member was selected. Seventy-six galaxies satisfied requirements. A 25° field of scan angle about the galaxy position, accumulated over ~4 days about the one of maximum exposure, was fitted with a fixed source at the galaxy position and as many other sources as necessary to fit the remainder of the field. Negative values for the source count rate were allowed. After correcting for effective exposure for each fixed source a count rate distribution was found. This was consistent, to within 1σ errors, with zero. This result implies that

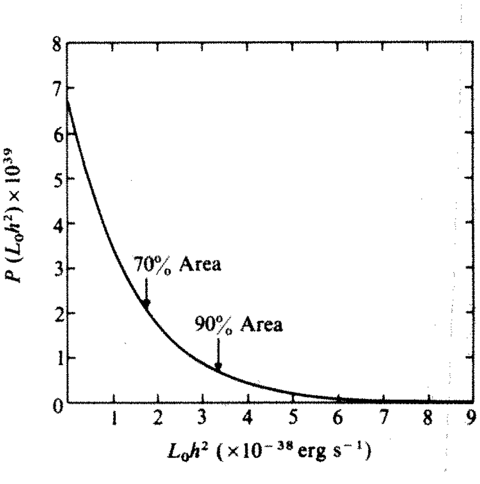

Fig. 1 The L_0h^2 probability function resulting from the application of a luminosity function $F(L, L_0)=(1/L_0h^2)\exp(-L/L_0h^2)$ to the sample of 76 normal galaxies. The result fits the indicated exponential function. The values of L_0h^2 bounding 70% and 90% of the area are shown, that is the upper limits to L_0h^2 at these respective confidence levels. $P(L_0h^2)\propto\exp(-L_0h^2/1.46\times10^{38})$.

0028-0836/79/370127—02$01.00

we can only determine upper limits to the average luminosity for various model luminosity distributions.

The simplest model which can be examined is one in which all galaxies are assumed to have a standard luminosity, Lh^2. Then the probability of observing the ith member of the 76 galaxies with its measured luminosity, L_ih^2, and associated standard deviation, σ_i, is $P_{si}(Lh^2) = (\sigma_i(2\pi)^{1/2})^{-1} \exp(-z_i^2/2)$, where $z_i = (L_i - L)h^2/\sigma_i$. Hence the likelihood function for the measured luminosities of the complete sample is $P_s(Lh^2) \propto \exp(-(\sum_i(z_i^2/2)))$. The values for σ_i were calculated from the standard deviation of the count rate distribution for the selected galaxies after this value had been confirmed to be consistent with values derived using random sample positions on the sky. The function $P_s(Lh^2)$ is of a gaussian form. The values of Lh^2 bounding 70% and 90% of the area are 1.5×10^{38} erg s^{-1} and 2.7×10^{38} erg s^{-1} respectively, which are the upper limits to the standard normal galaxy luminosity at these respective confidence levels. Even for a value of H_0 of 50 km s^{-1} Mpc^{-1} the results show that the average X-ray luminosity of normal galaxies is $\lesssim 10^{39}$ erg s^{-1}. This is a little lower than the X-ray luminosity of our Galaxy. However, we note that the average optical luminosity of the chosen galaxies in the B system is $(2 \times 10^9/h^2)L_\odot$ and the appropriate value for our Galaxy with which this should be compared is $11 \times 10^9 L_\odot$ (the mean orientation value estimated from the galactic pole value given in ref. 9).

More realistically, the luminosity function of the galaxies can be assumed to be an exponential, $F(L, L_0) = (L_0h^2)^{-1} \exp(-L/L_0h^2)$. The probability of observing the ith member of the 76 galaxies with its measured luminosity is now $P_i(L_0h^2) = \int F(L, L_0)P_{si}(Lh^2)\,\mathrm{d}L$. The product over all values of i gives the likelihood function for the complete sample. As shown in Fig. 1, it is approximately exponential. The 70% and 90% upper limits to L_0h^2 are now 1.8×10^{38} erg s^{-1} and 3.4×10^{38} erg s^{-1}, in reasonable agreement with the simple model.

The method generates a strong distance-dependent weighting factor. Because the answer is dominated by the closest 10 galaxies, selection effects may be important. To investigate this we divide the galaxies by distance into three bands. The number of galaxies per band increases with distance so that the three calculated luminosity upper limits are roughly equal. We find that they are ~3 times those quoted above. Thus we conclude that, to within a factor of 3, the 76 galaxies form a homogeneous class of which the closest 10 are not particularly anomalous. This is further confirmed in that the mean count rate for these 10 is within 1σ of the mean of the total sample.

Based on these results, we can make an h-independent comparison of the emissivity of galaxies with that of the diffuse background. The density of normal galaxies is calculated to be $\simeq 0.13h^3$ Mpc^{-3}. This uses a likely maximum value for the optical luminosity density of galaxies of $2.6 \times 10^8 hL_\odot$ Mpc^{-3} (see ref. 10) and the average luminosity for our sample as given above. For the detector fields of view we are using (defined as R15 in ref. 4) and applying the 90% upper limit criterion for the exponential luminosity distribution model, we find an emissivity of $< 2.7 \times 10^{45}h$ ct s^{-1} Mpc^{-3}. This is to be compared with the diffuse background emissivity of $\sim 3 \times 10^{47}h$ ct s^{-1} Mpc^{-3}. Thus normal galaxies contribute $\lesssim 1\%$.

Van Paradijs[6] has calculated the normal galaxy contribution to the X-ray background by modelling the X-ray luminosities of galaxy constituents. He estimates 0.5–2.8% (2–10 keV) for no evolution, but investigates several ways in which this value may be increased. While we cannot address those involving evolution, our calculations indicate that further non-evolutionary effects are not important.

By using a sample of objects we have investigated emission at luminosities lower than those for which we can study individual discrete sources and have shown that normal galaxies do not apparently provide the numerous low luminosity X-ray sources which could make up the 2–60-keV diffuse background. Indeed, upper limits suggest luminosities comparable with, or a little less than, that of the Galaxy. This is consistent with the fact that the average optical luminosity of the sample galaxies within ~20 Mpc is slightly lower than that of the Galaxy. An upper limit of ~1% of the diffuse background from such sources is derived.

Radiolytic reduction of ceric ions in water DMSO mixtures and radioprotection

A. M. Koulkes-Pujo, M. Moreau & J. Sutton

CNRS and DRA/SRIRMa—CEN. Saclay B.P. No 2 91190 Gif Sur Yvette, France

It is convenient to classify mechanisms of radioprotection into those that involve fast radiation chemical processes and those in which the protection is the result of changes in the cell biochemistry. In the former, the added protectors have two principal effects: OH scavenging which reduces the radiosensitised damage and fast chemical repair processes involving hydrogen donation from the protector to the target radical. Typical of the first type of protector is dimethyl sulphoxide(DMSO)[1] because it is known to be a good OH scavenger ($k_{\mathrm{OH+DMSO}} = 5 \times 10^9$ mol^{-1} s^{-1}. (ref. 2). We have attempted to establish the redox properties of the OH radical adduct[3] as well as those of H_2O_2 or H and HO_2 radicals in water–DMSO mixtures. To this end we added to the solutions containing 0.5 M H_2SO_4, ceric ions at concentrations varying from 2.5×10^{-3} to 5×10^{-2} M. The Ce^{4+} reduction yield was determined as a function of the DMSO content in the solution, by irradiating the mixture with γ rays, in the presence or absence of air. The details of the experimental procedure will be given elsewhere. We report here that the yields (G) are independent of the Ce^{4+} concentration in the range studied and of the presence or absence of air, and depend only on the DMSO concentration.

Figure 1 shows the rate of disappearance of Ce^{4+} plotted against the DMSO concentration. One sees that the $G(-Ce^{4+})$ reaches a plateau value of 17.9 ± 0.2 between 0.3 M and 1.4 M in DMSO, or 2–10% by volume. This reduction yield is very high and has never been observed previously for any solute in aqueous systems. The yield of Ce^{4+} reduction in aqueous solution is 2.5 ± 0.3 and the reduction is accompanied by O_2 formation with a yield of 0.8. In the case of deaerated water–DMSO mixtures, there is no formation of O_2.

In acidified water, the intermediate species are H, OH and H_2O_2, with respective yields: $G_{\mathrm{H}} = 3.65$, $G_{\mathrm{OH}} = 2.95$, $G_{\mathrm{H_2O_2}} = 0.8$ (ref. 5). The reduction yield of Ce^{4+} is expressed as: $G(-Ce^{4+}) = G_{\mathrm{H}} + 2G_{\mathrm{H_2O_2}} - G_{\mathrm{OH}} = 2.3$ (ref. 4). If DMSO transforms both the escaping OH radicals as well as the hydrogen peroxide precursors into reducing radicals, so that each OH

0028–0836/79/370128—02$01.00

gives rise to three equivalents of reduction then the yield of reduction of Ce^{4+} may reach a value corresponding to the equation: $G(-Ce^{4+}) = G_H + 6\ G_{H_2O_2} + 3\ G_{OH} = 17.3$. The Ce^{4+} reduction reactions by these DMSO radicals would be stoichiometrically equivalent to following thermodynamically possible reactions of H_2O_2 and OH:

$$Ce^{4+} + H_2O_2 \rightarrow Ce^{3+} + HO_2 + H^+$$

$$Ce^{4+} + HO_2 \rightarrow Ce^{3+} + H^+ + O_2$$

$$Ce^{4+} + OH + H_2O \rightarrow Ce^{3+} + H^+ + H_2O_2$$

In these equations the yield corresponding to the capture of the radicals involved in the back reaction to form water is not taken into account. If DMSO scavenges these species the reduction yield should increase. Actually, the experimental value at the plateau is a little higher (17.9 ± 0.2) which may be the result of two simultaneous effects: an increase of the capture of the radicals coming from water which tends to increase $G(-Ce^{4+})$ and a greater participation of transitory species coming from DMSO radiolysis of which the overall yield may be smaller than that of water. This latter conjecture follows from the decrease of $G(-Ce^{4+})$ observed at DMSO concentrations from 1.4 M up to pure DMSO where the reduction yield becomes 13.9 ± 0.5. This value is still quite large suggesting that all the intermediates coming from DMSO also reduce Ce^{4+}. This yield then corresponds to $3\ G_{ox} + G_H$, G_{ox} being the yield of oxidising species coming from $DMSO^+$ created in the primary ionisation process. G_{ox} and G_H have been determined as equal to 3.6 and 2.1 respecitvely.[6]

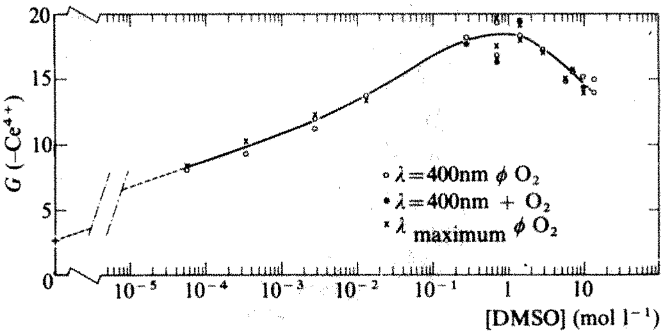

Fig. 1 The rate of disappearance of Ce^{4+} with the DMSO concentration.

It seems clear that the radicals formed by the reaction of DMSO with OH, H_2O_2, H or HO_2 all reduce Ce^{4+}. So DMSO not only acts as a good OH scavenger, suppressing an oxidising species, but the radical formed may also have reducing properties. This latter point could be important for the use of DMSO as a radioprotector. Another important point is the experimental observation of the absence of oxygen during this reduction reaction either by H_2O_2 or by HO_2. HO_2 like OH may give an adduct with DMSO which has reducing properties, but the reaction does not form O_2. This may also increase the radioprotective properties of DMSO by suppressing a very harmful radical HO_2 and by avoiding the formation of O_2 which is itself known to be a good radiosensitiser.

The synthesis of fluor-analogues of natural asbestos by unidirectional crystallisation

M. Campbell, A. Maries & P. S. Rogers

Nuffield Research Group, Department of Metallurgy and Materials Science, Imperial College, London SW7, UK

A previous letter[1] reported a novel technique for the preparation of aligned fibrous crystals by drawing filaments of glass through a supported molten zone. The method was subsequently modified so that the filament is drawn from a melt through an orifice in the base of a conical platinum crucible[2]. This technique has now been successfully applied to the preparation of filaments consisting of aligned fibres of fluor-amphiboles, synthetic analogues of natural amphiboles with isomorphous replacement of hydroxyl by fluorine. These aligned fibrous crystals can be compared with natural amphibole asbestos.

Considerable work has been carried out, particularly in the USSR, to synthesise fibrous asbestos[3–5]. The fibres produced, 80–90% fluor-amphibole, occur as a mass of matted fibres with a short brush-like growth on the surface. Fibres from the brush-like growth can be up to 3.5 cm long, although those in the bulk are very much shorter; diameters are between 0.5 and 10 μm. The dynamic nature of the present technique enables filaments of axially aligned fibres to be drawn to whatever length is desirable, limited only by the dimensions of the experimental arrangement. Moreover a greater degree of control over the crystal diameter and phase assemblage is possible by varying such parameters as melt temperature, thermal gradient, crystallisation rate (via drawing speed), nozzle diameter and hence filament diameter. Figure 1 summarises the effect of certain parameters for a single crystallising phase, which have been discussed previously[2]. Briefly it can be seen that the temperature of crystallisation T_c, decreases with increasing drawing speed V

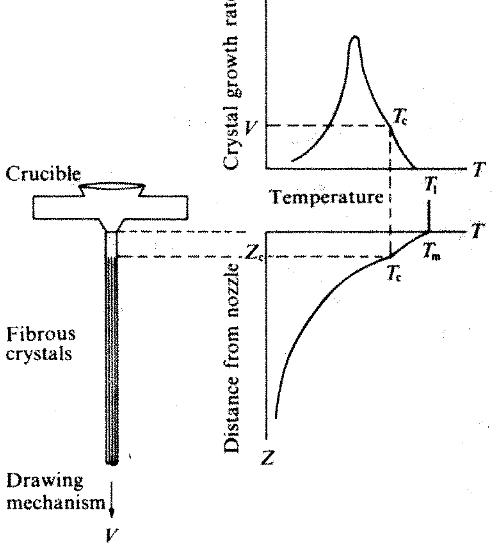

Fig. 1 Schematic diagram of apparatus for crystallisation from the melt (not to scale). Crucible lid with funnel has been omitted for clarity. T_m, T_l, T_c are melt, liquidus and crystallisation temperatures respectively; z_c, distance of crystal growth front from nozzle; V, drawing speed. Nozzle diameter is 0.9 mm and z_c is up to 1 mm.

Table 1 Batch compositions used successfully to produce fluor-amphiboles

Fluor-amphibole	Batch composition used	Liquidus	Crystalline phases in drawn filament
Fluor-magnesiorichterite $Na_2MgMg_5Si_8O_{22}F_2$	$Na_2Mg_6Si_8O_{20}F_6$	1,280 °C	(1) Water-swelling layered compound, probably fluor-tetrasilicic mica ($Na_2Mg_5Si_8O_{20}F_4$)[9] (2) Clinoenstatite (3) Small amount of fluor-magnesiorichterite
Fluor-tremolite $Ca_2Mg_5Si_8O_{22}F_2$	$Ca_2Mg_5Si_8O_{22}F_2.SiF_4$	~1,500 °C	(1) Clinoenstatite and diopside (as two solid solutions) (2) Fluor-tremolite
Fluor-richterite $Na_2CaMg_5Si_8O_{22}F_2$	$Na_2CaMg_5Si_8O_{22}F_2.Na_2SiF_6$	1,210 °C	(1) Fluor-richterite (2) Diopside and clinoenstatite additionally in certain conditions

until the maximum crystal growth rate is reached. The temperature of the melt T_m, which is above the liquidus T_l, determines the distance of the growth front from the nozzle (z_c).

The fluor-amphiboles that we have synthesised by this method are fluor-magnesiorichterite, fluor-tremolite and fluor-richterite; chosen because X-ray and optical data are readily available[6,7]. The first two have been produced here only in conjunction with pyroxene phases but the latter has been obtained as the only crystalline phase in the drawn filaments.

One of the main difficulties which arises when this method is applied to the synthesis of fluor-amphiboles is the loss of volatile fluorides from the melt; these are mainly SiF_4, with some NaF if Na is present and possibly some HF by hydrolysis. To reduce loss by volatilisation, the original cell[2] was slightly modified by welding a platinum lid on to the conical crucible, with a narrow funnel to allow recharging, closed at the top by a removable alumina stopper. Although this does not give a gas-tight seal, it does reduce the fluorine loss considerably. Starting materials were the anhydrous compounds MgO, SiO_2, Na_2CO_3, $CaCO_3$ and MgF_2, all of analytical purity. Batches were made up from these in proportions corresponding to the fluor-amphibole formula with a little extra fluorine and/or sodium. The most successful of the batch compositions used for each of the fluor-amphiboles is shown in Table 1, together with the crystalline phases produced and identified by powder X-ray diffraction.

In all cases where batch composition was close to the formula of fluor-magnesiorichterite the dominating phase was a water-swelling layered compound which contained twice the number of fluorine ions per silicate group as did the amphibole, at the expense of the latter. The amount of amphibole formed falls rapidly to zero as volatilisation reduces the F and Na available. A considerable amphibole yield was obtained from melts of composition close to that of fluor-tremolite, but always accompanied by pyroxene.

Reincorporation of sodium, together with calcium, into the batch reduced the liquidus temperature so that lower melt temperatures could be used and hence loss by volatilisation reduced, giving a very much higher amphibole/pyroxene ratio in drawn filaments. In fact over most of the temperature range possible for drawing, filaments were free from pyroxene, fluor-richterite being the only crystalline phase detectable by powder X-ray diffraction. The range of melt temperatures found possible for drawing was approximately 1,200 to 1,380 °C, whilst pyroxene appeared at the start of drawing above about 1,320 °C. However, the maximum drawing speed possible for crystallisation of fluor-richterite from this melt composition is somewhat low, 15 $\mu m\ s^{-1}$, compared with rates in excess of 60 $\mu m\ s^{-1}$ that have been used to draw filaments of the other two fluor-amphiboles. The X-ray pattern for fluor-richterite contained a few lines not recorded by Kohn and Comefero[7]. These, however, correspond to reflections permissible by the symmetry of the crystal structure (space group C2/m), and are in fact recorded for some other fluor-amphiboles and/or hydroxy-amphiboles[6-8]; moreover the reflections, including the 'extra'

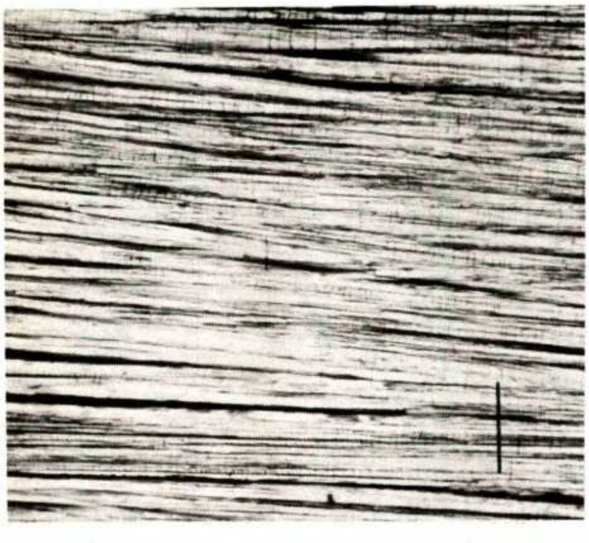

Fig. 2 Optical micrograph (transmitted light, crossed polars) of filament containing fluor-richterite and some pyroxene, drawn at 11 $\mu m\ s^{-1}$. Longitudinal section. Scale bar, 100 μm.

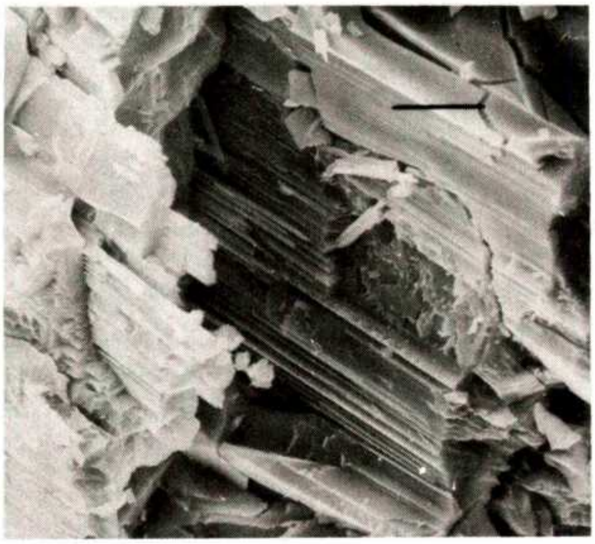

Fig. 3 Scanning electron micrograph of fracture surface of a filament containing fluor-richterite as the only crystalline phase. Scale bar, 10 μm.

reflections, correspond closely in intensity and position to the pattern given by a natural richterite from Langban, Sweden, supplied by the British Museum (Natural History) which matched the data reported by Huebner and Papike[8] for the synthetic richterite $Na_2CaMg_5Si_8O_{22}(OH)_2$.

Optical examination of thin sections of filaments, between 1 and 2 mm in diameter, reveal in most cases a well aligned, polycrystalline microstructure (Fig. 2) with fibres parallel to the filament axis. The high degree of alignment was confirmed by rotation X-ray diffraction. Crystal diameters vary according to conditions used but are rather large, being typically 10–20 μm, and in the case of fluor-richterite filaments free from pyroxene, larger than this (~20–60 μm). Transverse sections show that the fibre crystals are of pseudo-hexagonal or rhombic skeletal cross-section with cleavage planes at angles of approximately 56° and 124° as typical of amphiboles. The residual glass is estimated from transverse sections to be approximately 10%.

Figure 3 is a scanning electron micrograph of a typical fracture surface of a fluor-richterite filament showing the very much finer sub-structure to these crystals, made up of laths a fraction of a micrometre thick.

Laser observations of the ground-state hyperfine structure of sodium and of temperatures in the upper atmosphere

A. J. Gibson, L. Thomas & S. K. Bhattachacharyya

SRC Appleton Laboratory, Ditton Park, Slough, Berks, UK

The height distributions of sodium between about 80 and 100 km have been measured by several groups from observations of the resonance scattering of a tuned laser beam[1–7]. Furthermore, estimates of temperatures in this height range have been made[4] by incorporating a sodium cell of known temperature in the receiver of the laser radar system. In all these measurements, the linewidths of the lasers employed have been comparable with, or greater than, that of the sodium D_1 or D_2 resonance line. The ground level of sodium atoms, 3s $^2S_{1/2}$ consists of two hyperfine-structure components at −1.107 GHz and 0.664 GHz relative to the centroid[8]. Because of the corresponding hyperfine structure of the upper levels, 3p $^2P_{1/2}$ for D_1 and 3p $^2P_{3/2}$ for D_2, four components contribute to the D_1 and six to the D_2 complexes. Since the relative strengths and frequencies of the ten components are well known, the theoretical line shape can be computed[9]. For temperatures above about 6 K, blending of these components occurs and for temperatures below about 456 K the line profiles of both D_1 and D_2 complexes show two distinct peaks. In this letter preliminary measurements of the profile of the D_2 line using a tunable narrow-band laser are presented and used to deduce the temperature near the peak of the sodium layer.

The effects of saturated absorption and optical pumping between the hyperfine levels of sodium atoms observed in laboratory measurements[10,11] are expected to be negligible with the moderate output energy (20 mJ) and the transmitter beam divergence (2.5 mrad) used.

The laser transmitter system described previously[12] has been modified by extending the resonator length and incorporating a piezo-electric etalon of 20 mm spacing to provide a tunable linewidth of about 0.1 GHz, about one-thirtieth of the widths of the D_1 or D_2 complexes at temperatures in the 80–100 km height range. The laser frequency, laser triggering, and data recording were controlled by a programable calculator, interfaced with a digital-to-analogue converter and with 10 range-gated photon counters. The laser frequency was changed, and the photon counts were transferred to the calculator, after every laser pulse. The system was programmed to perform successive scans each of eight equally-spaced laser frequencies spanning the D_2 line; after 75 scans comprising 600 laser pulses, occupying about 10 min, the data were recorded on magnetic tape.

The first results, based on 1,200 laser pulses during between 2300 and 2330 h on the night of 30 January 1979, are presented in Fig. 1*a*. This shows the ratio, R_i, of the signal from the sodium layer (82–98 km) to that from a lower height range (28–30 km), which is dominated by Rayleigh scattering, with the standard error, σ_i of this ratio for each frequency, $i = 1$ to 8. The variation of this ratio with frequency represents the corresponding variation of sodium atom cross-section. Also shown is the theoretical curve which gives the best fit to the data. Since an absolute calibration of the laser frequency was not available, this frequency was taken to be a linear function, $A+Bi$, of the frequency number, i, with two unknown parameters A and B. The theoretical curve is thus a function of four independent unknown parameters, that is

$$S_i(T,A,B,C) = C\sum_{h=1}^{6}\frac{f_h}{\nu_h\sqrt{T}}\exp\{-(A+Bi-\nu_h)^2Mc^2/2\nu_h^2kT\} \qquad (1)$$

where f_h and ν_h are the strength and frequency of the hth hyperfine component, M the mass of a sodium atom, c the velocity of light and k is Boltzmann's constant. The temperature T, and C, a scale factor for the ordinate in Fig. 1*a*, are the other two unknowns. The best fit of equation (1) to the data was obtained by minimising the χ^2 statistic given by

$$\chi^2 = \sum_{i=1}^{8}\{R_i - S_i(T,A,B,C)\}^2/\sigma_i^2 \qquad (2)$$

A test of the hypothesis that each of the observed values of R_i is a random sample from a normal distribution having mean $S_i(T,A,B,C)$ and variance σ_i^2, can be applied by determining the probability, $P(\chi^2)$, of the value of χ^2 obtained being exceeded in random sampling. The procedure for determining the means involves four nonlinear constraints, the equations

$$\frac{\partial(\chi^2)}{\partial q} = 0 \quad \text{where } q \equiv T, A, B \text{ or } C \qquad (3)$$

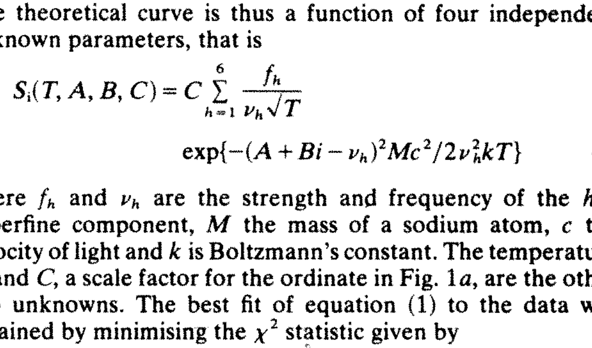

Fig. 1 *a*, Ratio of the sodium to Rayleigh scattered signals as a function of laser frequency for 1,200 laser shots on 30 January 1979, together with the theoretical lineshape which provides the best fit to the data. *b*, The probability $P(\chi^2, 4)$ as a function of temperature for the curve-fitting in *a*.

and hence we take the number of degrees of freedom as 4, obtaining a value $P(\chi^2, 4)$ of 0.67, indicating that the data are consistent with the theoretical relation (1).

Figure 1*b* shows the value of $P(\chi^2, 4)$ plotted as a function of T after χ^2 has been minimised with respect to A, B and C. The best value of T, indicated by the maximum of this curve, is (222±16) K; the error estimate corresponds to one-half the half-width of the P curve at $P=0.05$. Subsequent measurements during May 1979 indicated substantially lower temperatures, near 170 K, between 90 and 94 km. Small negative corrections can be applied to the measured temperatures after taking into account the finite laser linewidth. If $\Delta\nu_{\mathrm{D}}$ represents the Doppler linewidth of each hyperfine component and $\Delta\nu_{\mathrm{L}}$ is the laser linewidth, it can be shown by replacing equation (1) by its convolution with a gaussian laser line-shape function that the first-order correction is given by

$$\frac{\Delta T}{T} = -(\Delta\nu_{\mathrm{L}}/\Delta\nu_{\mathrm{D}})^2 \tag{4}$$

which amounts to less than 3K for our measurements.

It is to be expected that the present method of measuring upper atmosphere temperatures will be capable of greater accuracy than that involving the use of a sodium absorption cell in the receiver which depends on integration over the spectral line shape. The accuracy currently available with the new technique can be substantially improved by the use of high laser repetition rates, improvements in receiver sensitivity and maximum photon counting rates, and optimum choice of laser frequencies. The capability of observing the small-scale structure of temperature offered by this laser technique is directly relevant to studies of the thermal balance of the upper mesosphere, of the neutral and ion chemistry involving temperature dependent rate coefficients, of noctilucent clouds and of short-wavelength atmospheric-wave disturbances. This ground-based technique could, therefore, be a useful supplement to existing satellite measurements of temperature based on observations of thermal emissions.

Environmental fluctuation effects on the global energy balance

C. Nicolis

Institut d'Aéronomie Spatiale de Belgique, 1180 Bruxelles, Belgique

G. Nicolis

Faculté des Sciences de l'Université Libre de Bruxelles, Campus plaine, CP 226, 1050 Bruxelles, Belgique

Much effort has been devoted to developing simple energy-balance climatic models. Although consideration of latitudinal energy transfer[1–4] gives more complete answers it has become clear that global, 'zero dimensional' models may also provide much useful information[5,6]. These models have the form:

$$C\frac{\mathrm{d}T}{\mathrm{d}t} = Q(1-a(T)) - \varepsilon\sigma T^4 \tag{1}$$

T **is the surface temperature,** ***C*** **the thermal inertia coefficient,** ***Q*** **the solar constants,** ***σ*** **the Stefan constant,** ***a*(*T*)** **the (generally temperature-dependent) albedo, and** ***ε*** **the emissivity of the Earth–atmosphere system. The variability of the climate system rests, therefore, on certain types of change experienced by the solar output, or by such planetary factors as emissivity, albedo, cloudiness and so forth. In addition to some long-term trends of the solar constant[7], it has been suggested that the Sun is in an almost-intransitive state[8,9]. Hence, it may generate large fluctuations around some mean value of its output, which will be perceived by the Earth–atmosphere system as an 'external noise' affecting** ***Q*****. The fact that the terrestrial atmosphere is likely to be in an almost intransitive state[10] can also generate appreciable fluctuations in factors influencing the albedo and the emissivity. In the absence of precise knowledge of the mechanism of these fluctuations, one is again tempted to regard them as an 'external noise' affecting** ***a*(*T*)** **and** ***ε*****. We explore here the qualitative effect of such environmental fluctuations in the thermal regime[13], at the level of a zero-dimensional planetary model. Previous analyses of nonlinear systems of chemical and biological interest[11,12] have shown that external noise can dramatically affect the macroscopic behaviour predicted by the deterministic equations of evolution, if coupled to these equations in a multiplicative way.**

All cases considered here refer to such multiplicative coupling. In this respect, our analysis differs from the work of Lemke[14] and Fraedrich[5] which is concerned primarily with additive fluctuations. Although such fluctuations are important, clearly the multiplicative coupling is a more appropriate representation of the dynamics of a complex system such as the Earth–atmosphere.

From the mathematical point of view, the effects of external noise change equation (1) to a stochastic differential equation, to which the Itô calculus can be applied[15]. Let us adopt an abstract notation and decompose equation (1) into two pieces, $f(T)$ and $g(T)$, which are linearly coupled through some parameter λ

$$\frac{\mathrm{d}T}{\mathrm{d}t} = f(T) + \lambda g(T) \tag{2}$$

Let λ be subject to environmental fluctuations referred to above. For simplicity, we take the idealised picture of a gaussian white noise. (The possible shortcomings of white noise, related to the possibility that the fluctuating parameters reach negative values, means that in each case the nature of the boundaries of the stochastic process must be checked carefully.) Hence[15]:

$$\lambda = \bar{\lambda}(1+\xi_t)$$

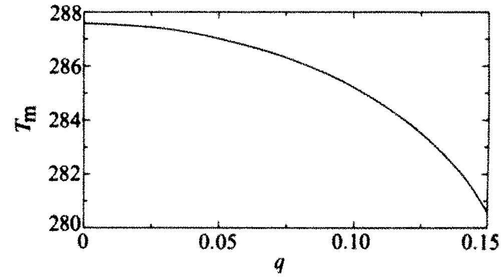

Fig. 1 Dependence of most probable temperature T_m on variance q. Q fluctuates around the mean value of 1.95 cal cm^{-2} min^{-1}. The thermal inertia coefficient used in the simulation is $C = 7.5$ kcal cm^{-2} K^{-1}. The emissivity ε is kept at the value 0.6, and the albedo is $a = \alpha + \beta T$ where $\alpha = 2.7888$, $\beta = -0.0086$.

0028-0836/79/370132—03$01.00

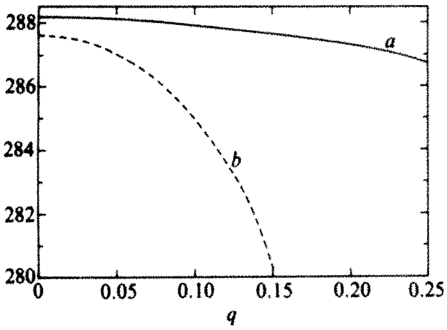

Fig. 2 T_m versus q when ε fluctuates around the value of 0.6. The thermal inertia coefficient is as in Fig. 1. *a*, The albedo is taken to be constant, $\bar{a} = 0.31$. *b*, The albedo is described by $a = \alpha + \beta T$ where $\alpha = 2.788$, $\beta = -0.0086$.

where $\bar{\lambda}$ is the value of λ appearing in the deterministic description and ξ_t is the derivative of a Wiener process, W_t:

$$\langle \xi_t \rangle = 0$$
$$\langle \xi_t \xi_{t'} \rangle = q^2\, \delta(t - t') \tag{3}$$

Equation (2) then takes the form (we now use the Itô rather than the Stratonovich interpretation[15]):

$$\mathrm{d}T = [f(T) + \bar{\lambda} g(T)]\,\mathrm{d}t + q\bar{\lambda} g(T)\,\mathrm{d}W_t \tag{4}$$

which is equivalent to a Fokker–Planck equation for the probability distribution $P(T, t)$:

$$\frac{\partial P}{\partial t} = -\frac{\partial}{\partial T}[f(T) + \bar{\lambda} g(T)]P(T, t) + $$
$$+\tfrac{1}{2} q^2 \frac{\partial^2}{\partial T^2} \bar{\lambda}^2 g^2(T) P(T, t) \tag{5}$$

A macroscopically observable stable temperature clearly corresponds to a maximum of the steady-state distribution $P_{st}(T)$ which obeys the equation:

$$-[f(T_m) + \bar{\lambda} g(T_m)] + \frac{q^2}{2} \frac{\mathrm{d}}{\mathrm{d}T}[\bar{\lambda}^2 g^2(T_m)] = 0 \tag{6}$$

we now apply this relation to the following situations.

(1) Q fluctuates around the present-day value of 1.95 cal cm^{-2} min^{-1}. If the planetary albedo, a, is taken to be constant, the noise becomes additive and equation (6) gives $\mathrm{d}g^2/\mathrm{d}T = 0$; hence one obtains the usual value of planetary temperature corresponding to present-day conditions. On the other hand, the fluctuations of Q begin to be effective if the planetary albedo depends on T. The simplest non-trivial such dependence is given by the linear function $a(T) = \alpha + \beta T$. Such expressions have been used widely[5,6,16], at least in the range between the highest temperature than can exist when the whole Earth is covered with ice, and the lowest possible temperature when no ice is present. Note that some pathological properties of linear albedo–temperature feedback pointed out by Schneider and Gal-Chen for one-dimensional energy-balance models[17] are not necessarily reproduced in a zero-dimensional planetary model. In the latter, the albedo must depend on the planetary temperature in a continuous fashion at least in a range of temperatures not too remote from present-day conditions.

(2) ε fluctuates around some mean value $\bar{\varepsilon}$ corresponding to a surface temperature of 287.6 K in the absence of fluctuations. The planetary albedo is taken to be, successively, equal to a constant value $\bar{a}$ or to a linear function of T. Physically speaking, fluctuations of ε at fixed albedo could be attributed to random modifications of atmospheric composition.

(3) a and ε both follow the fluctuations of cloudiness, n. The parameterisations of a and ε in terms of n are taken from Cess[16] and Schneider[18], and

$$n = 0.5(1 + \xi_t) \tag{7}$$

We now describe the results of some representative numerical simulations.

Figure 1 shows T_m as a function of q, the square root of the variance of Q. As q increases from 0.005 to 0.05 the most probable temperature decreases from about 287.6 K to 287 K. For higher q the decrease of T_m is more pronounced.

Finally, when $q \geq 0.16$ then T_m drops to extremely low values. The precise numbers are of no importance here, as the model should not be valid anyway for such ranges of temperature and additional feedback mechanisms could take over. The main point therefore of Fig. 1 is the tendency for runaway to lower temperature values.

Curve *b* of Figure 2 shows the analogous result in terms of the variance of ε for a linear albedo–temperature feedback (note that in this case equation (6) is an equation of seventh degree in T_m—a degree higher than that of the deterministic equation). Again, for $q \geq 0.16$ there is a similar tendency of runaway to extremely low values of T_m. Curve *a* describes the situation in the constant albedo case: the same tendency to lower T is observed, although there seems to be no runaway effect.

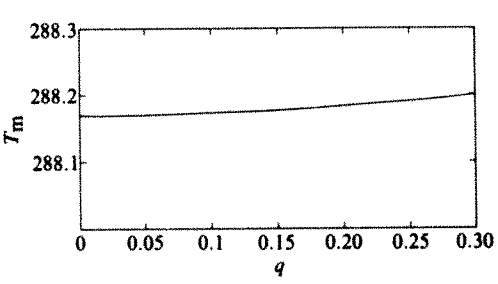

Fig. 3 Effect of fluctuating cloudiness using the following parameterisations. For the albedo (see ref. 16): $a = 0.18 + 0.26n$. For the emissivity (see ref. 18, for an effective cloud height of about 6.5 km): $\varepsilon = 0.71 - 0.22n$.

The effect of fluctuating cloudiness is rather different and described in Fig. 3 (here again, the equation for T is of seventh degree). As q increases from 0 to 0.30, the temperature remains substantially the same, varying by less than one-tenth of a degree. It appears that the fluctuations have opposite effects on the input and output terms in equation (4), thus giving a small overall effect. Another cause of the smallness of the effect may be that in the parameterisation of equation (7), cloudiness is taken to be temperature independent.

The thermal regime in a fluctuating environment seems thus to be established at temperatures that may differ substantially from those corresponding to a constant environment (actually, there always seems to be a tendency towards decreasing values). Eventually, in the presence of giant fluctuations a runaway regime may be reached in which there cannot be a stationary solution in a physically reasonable temperature range. These unexpected phenomena are all due to the multiplicative coupling between fluctuating parameters and the temperature[11]. In the case of additive noise or of linearised response[5,14] the effect would vanish because the function g^2 in equation (6) would be constant. One would thus recover the solution of the deterministic rate equation. It would be interesting to extend the present investigation to more realistic types of noise and to conditions prevailing in other planets, where a runaway regime is believed to exist.

We thank Dr W. Horstkemke for helpful discussions.

Intercalation of amino acids and polypeptides into 2H-TaS$_2$

V. M. Chapela* & G. S. Parry

Department of Chemical Engineering and Chemical Technology,
Imperial College, London SW7, UK

2H-TaS$_2$ can be intercalated by organic amines and empirical rules have been formulated[1–3] governing the properties that chemical species must possess in order to intercalate. One of these rules is that molecules in which the nitrogen is basic (pKa$>$4) usually form stable compounds provided the amine does not have bulky substituents. For certain amino acids, the values of pKa are significantly larger than this critical value (for example, glycine $pK_2 = 9.78$)[5] so that if the zwitterion is in a state where it can function as a base, it might be expected that the amino acid would intercalate 2H-TaS$_2$. This prediction has been verified for a number of amino acids. The discovery of these intercalation reactions provides a new range of intercalated compounds for study and also opens up the possibility of *in situ* polymerisation.

Saturated solutions of amino acids (chromatographically homogeneous or laboratory grade purity) in distilled water were prepared in a borosilicate glass ampoule at 75 °C. Samples of about 0.15 g of 2H-TaS$_2$, in either powder or single crystal form, were added and the ampoule was then sealed in air. The tubes were placed in an oven at 100 °C for between 1 and 3 weeks.

The intercalation reaction was monitored by opening capsules sequentially and examining the powder on an X-ray diffractometer with CuKα radiation. When the reaction product was entirely the stage 1 compound (judged by the position and line breadth of the 00l reflections), the new interlayer separation was obtained by extrapolating the parameter estimated from individual 00l reflections to $\theta = 90°$ as a function of cot θ cos θ. Selected single crystals were also examined using a single crystal goniometer with MoKα radiation.

The composition x in the formula TaS$_2$ (amino acid)$_x$ was determined using a Perkin-Elmer thermobalance. In making this calculation, the entire weight loss was attributed to amino acid for there was no sudden change in the rate of weight loss as might be expected if water was also intercalated along with the amino acid.

Superconducting transition temperatures were measured using a lock-in variable impedance method. Temperatures were measured using an Allen-Bradley carbon resistance thermometer calibrated against the vapour pressure of liquid helium and the superconducting transition temperatures of lead and niobium as calibration points. As noted in Table 1, certain compounds did not exhibit a superconducting transition between 1.2 and 15 K.

The intercalated species are shown in Table 1 and include amino acids such as glycine, β-alanine, L-proline, picolinic acid, diketopiperazine (glycine anhydride) as well as the polypeptides of glycine to pentaglycine. Attempts to intercalate isonicotinic acid, DL-proline and L-hydroxyproline were not successful. Values of the expanded gap (the difference between the layer separation before and after intercalation) show that, except for valine, the molecules lie parallel to the TaS$_2$ layer with the p$_z$ orbital containing the nitrogen lone pair orientated perpendicular to the layer. The results indicate that the peptide bond actively promotes intercalation. Thus glycine anhydride does not possess any amino groups at all and intercalation must have involved the two ring nitrogen atoms. Moreover pentaglycine (a 16-atom chain excluding hydrogens) remains parallel to the layer with an expanded gap of 3.4 Å in contrast to pentadecylamine[1] (also a 16-atom chain) which lies perpendicular to the layer with a 39 Å expanded gap.

Single-crystal X-ray studies indicate that the a-axis orientation of the matrix crystal is preserved on intercalation although the layer stacking order is destroyed (only hk rods are observed). This suggests a random sequence of stacking faults in contrast to the regular sequence of faults found in 2H-TaS$_2$(pyridine)[4]. Possibly the present choice of reaction conditions does not favour a highly orientated reaction product.

¶ The difference between the interlayer separation before and after intercalation.

0028–0836/79/370134—02$01.00

The superconducting transition temperatures are generally lower than for the amine intercalates[1] suggesting that the density of states at the Fermi level is modified less than in the amines. No superconducting transition could be detected in three of the compounds. The result was unexpected and further study is necessary before we can comment on the significance of this finding.

We thank Dr Forgan (University of Birmingham) for allowing us to use his superconducting transition apparatus. V.M.C. acknowledges financial support from the CIM-UNAM and UNAM-Banco de Mexico scholarship programme.

Effect of *in situ* leaching on amino acid racemisation rates in fossil bone

Kenneth King, Jr

Lamont–Doherty Geological Observatory of Columbia University,
Palisades, New York 10964

Jeffrey L. Bada

Scripps Institution of Oceanography, and Institute of Marine Resources,
University of California, San Diego, La Jolla, California 92093

Amino acid racemisation reactions provide a promising approach for estimating the absolute ages of fossil bones[1]. However, an important question remains unanswered: what is the effect of *in situ* leaching on apparent racemisation rates[2,3]? We report here the relationship between leaching history and the corresponding D/L aspartic acid ratio for 12 well-dated fossil samples, using γ-carboxyglutamic acid (Gla) as a quantitative index of leaching[4], in an attempt to resolve this problem.

High-temperature simulation studies provided the initial evidence that intensive leaching of bone organic matrix can substantially change the D/L ratios of the matrix amino acids and consequently generate misleading apparent ages[2,3]. In contrast, racemisation ages of natural fossil samples (presumably representing a range of different leaching histories) were found to be in close agreement with independently determined radiocarbon dates[5–7]. Availability of a bone-specific leaching index (Gla) unaffected by environmental organic matter[4] has allowed us to study directly the possible role of leaching in the alteration of the D/L ratios used for the amino acid dating of fossil bones.

The six pairs of fossil bone samples in which Gla was measured included a wide range of ages, environmental temperatures, and leaching histories (Table 1). The first two samples (Buhen Horse and Mindanao SU-1) came from localities having nearly identical air temperatures. However, their respective environments were quite different in terms of annual rainfall—the Buhen Horse sample was from the arid Sudan ($0.4\ \mathrm{cm\ yr^{-1}}$ precipitation) and the Mindanao SU-1 sample was from an estuarine swamp in the Philippines ($232\ \mathrm{cm\ yr^{-1}}$ preciptiation)—and this is reflected by their Gla values of 845 and $516\ \mathrm{nmol\ g^{-1}}$, respectively. As percentages of the Gla concentration in fresh bovine bone (1,076 nmol per g bone[4]), the Gla content of the Buhen Horse sample is 79% and the Mindanao sample 48%. Both samples have the collagenous organic matrices expected in slightly to moderately leached specimens[2]. Despite a significant difference in leaching histories reflected by the Gla contents, the two samples show essentially equal racemisation rate constants (k_{asp}) when the environmental temperatures are taken into account.

Both of the La Jolla palaeo-Indian samples have undergone substantial leaching as shown by their low Gla values. Although sample SDM 16709 has a Gla content equivalent to only 5% of fresh bovine, its organic matrix is still collagenous in composition. When the D/L ratio of SDM 16709 is used to calibrate the racemisation reaction, the resulting racemisation age for W–12/76 is in good agreement with the radiocarbon date.

The sites at which the Olduvai Gorge and Nasera Rock Shelter samples were collected are only about 30 km apart. Both have been heavily leached, although the less intensely leached Olduvai Gorge sample (13% Gla content relative to fresh bovine bone) still has a collagen-like pattern. The calculated racemisation age of the Nasera Rock sample (using the Olduvai Gorge specimen for calibration) is within 8% of its radiocarbon date.

The Murray Springs and Double Adobe samples, very similar in age, are also intensively leached as shown by the Gla contents and the absence of collagen in both organic matrices. As a result of good agreement between the D/L aspartic acid ratios of the Double Adobe sample and the calibrating sample (Murray Springs), the calculated racemisation age is concordant with the radiocarbon age.

The two older samples from the Nasera Rock Shelter (levels 5A and 6) have similar radiocarbon ages. Both have undergone severe leaching and neither show detectable Gla nor a collagenous organic matrix. The racemisation age of level 6, based on a calibration with level 5A, is about 13% higher than the radiocarbon age.

The oldest pair of samples is represented by two from Mt Carmel. Both are leached to an extreme degree as shown by the absence of Gla in the Tabūn sample (non-collagenous) and the trace of Gla in the Sefunim specimen (collagenous). Although there is an age difference of ~14,000 yr between the Sefunim calibration sample and the Tabūn sample, the calculated racemisation age for the Tabūn specimen is within 8% of the radiocarbon age.

The data in Table 1 indicates concordance of aspartic acid racemisation age with radiocarbon data for each of the six unknown samples (despite measurable differences in leaching history between the unknown and calibration samples). Thus, *in situ* leaching seems to have a negligible effect on the racemisation parameters calculated from these six pairs of fossil bone samples.

How can this finding be reconciled with the original laboratory results showing significant alteration of racemisation rates with intensive leaching[2,3]? A closer examination of the

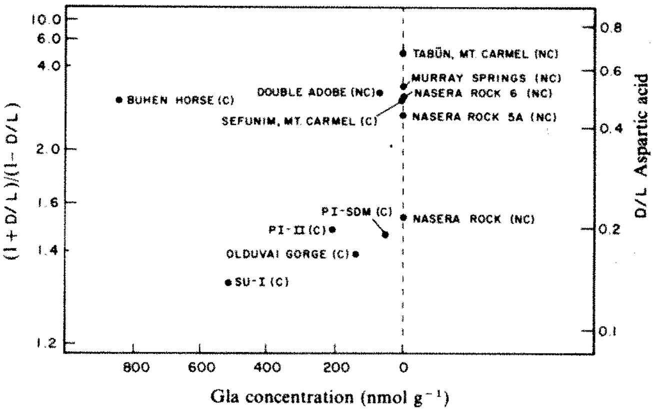

Fig. 1 Relationship between aspartic acid racemisation parameters and degree of *in situ* leaching. Intensity of leaching increases with decreasing values of Gla content. The parameter $\ln[(1+\mathrm{D/L})/(1-\mathrm{D/L})]$ is the key variable in the equation used to calculate racemisation ages[8]. C, collagenous matrix; NC, non-collagenous matrix.

0028–0836/79/370135—03$01.00

leaching data (Fig. 1) suggests an answer to this question and helps to define the conditions in which leaching could adversely affect racemisation calculations.

The 12 samples segregate into two major clusters (Fig. 1): a low aspartic acid D/L ratio group ($\bar{X} = 0.18$), and a high aspartic acid D/L ratio group ($\bar{X} = 0.51$). The lower cluster of five samples can be characterised as young in age ($\bar{X} = 4{,}100$ yr), moderately leached (only one sample has < 0.1 nmol Gla per g), and predominantly collagenous in composition (only one sample contains a non-collagenous organic matrix). In contrast, the other group of seven samples with higher D/L values has a mean age of 12,400 yr, generally exhibits intense leaching (five samples have undetectable or trace amounts of Gla) and contains predominantly non-collagenous matrices (only two samples display a collagen pattern).

Note that amino acid concentration (Table 1), another possible leaching index, generates a plot remarkably similar to the Gla plot (Fig. 1). With the exception of the Buhen Horse/Mindanao comparison, the sample having the higher amino acid concentration in each pair also had the higher Gla content. However, the Mindanao sample, with a 28% higher amino acid concentration than the Buhen Horse specimen, showed a 39% lower Gla content. This unusual relationship is thought to result from the interaction of two factors: (1) minimal solubilisation (through decreased chain length) of the collagen in the Mindanao sample during the short time interval represented (~500 yr); and (2) a more rapid loss of Gla in the Mindanao sample due to the intensive leaching conditions of its estuarine environment. Although more susceptible to perturbation by environmental contamination, amino acid concentration could be used as a leaching parameter in very heavily leached samples after Gla has disappeared.

It is probably significant that, with only one exception (the slightly leached Buhen Horse specimen), the sample used to calibrate the racemisation reaction is in the same group as the unknown sample to be dated. This suggests the possibility that each of the calibration samples has, in effect, calibrated the racemisation reaction in the corresponding unknown for degree of leaching as well as environmental temperature. This hypothesis may be tested by attempting to 'cross-calibrate' between the two groups using data from the Nasera Rock Shelter site (Table 1). If the k_{asp} value ($7.4 \times 10^{-5}\ \mathrm{yr}^{-1}$) used for the young (~2,000 yr BP) Nasera Rock Shelter sample (low D/L group) is used to calibrate the racemisation process for dating the Nasera Rock Shelter Level 6 sample (high D/L group), the resulting age estimate is 6,200 yr BP or 73% lower than the radiocarbon age. In addition, if the k_{asp} value of the calibration sample (postglacial exposure) is reduced by 40% to compensate for the lower integrated temperature of the older Nasera Rock Shelter (Level 6) sample (postglacial and glacial exposures)[9], the calculated amino acid racemisation age is only increased to 10,400 yr BP (55% less than the radiocarbon age). As shown in Table 1, the

racemisation age for this same sample calibrated with the Nasera Rock Shelter Level 5A sample (same high D/L group) is 26,000 yr BP, 13% higher than the radiocarbon date. This example further suggests that a 'cross-over' between the two groups in calibrating a racemisation reaction may introduce substantial error in estimating absolute age.

The need for intra-group calibration most probably stems from key compositional differences between the two groups produced, in part at least, by *in situ* leaching. Although detailed information on the relevant properties (for example, molecular weight, amino acid composition, and degree of racemisation) of each individual matrix component is not yet available, comparative total amino acid compositions provide some evidence for a requirement of compositional similarity between calibration and unknown samples. As shown in Table 1, four of the six racemisation calculations involved sample pairs having organic matrices of similar composition (2 collagenous; two non-collagenous). Note that the only successful cross-calibration between the two groups involves one of the compositionally similar pairs—the collagenous Buhen Horse and Mindanao SU-1 samples. These two samples also show the lowest degrees of leaching among the samples analysed. Successful calibration with pairs of similar organic matrices is not unexpected as the laboratory leaching data indicates changes in racemisation rates coincident with the compositional change from collagenous to non-collagenous matrix[10].

The remaining two pairs each involved a combination of different matrices—Olduvai Gorge (collagenous)/Nasera Rock Shelter (non-collagenous) and Sefunim (collagenous)/Tabūn (non-collagenous). An explanation for successfully achieving concordancy with these unlike matrices will require detailed characterisation of the major diagenetic components of each matrix to reveal key compositional and stereoisomeric similarities not evident in overall amino acid composition. Nevertheless, it is interesting that the calibration and unknown samples of each pair are in the same D/L group (Fig. 1) despite their dissimilar compositions.

No significant alteration in racemisation rates by *in situ* leaching was detected in this study of six pairs of fossil bone samples. The data (Fig. 1), however, suggest that the general concordancy observed between racemisation ages and radiocarbon dates may have resulted from a close matching of the calibration and unknown samples in each pair in terms of composition, leaching history and degree of racemisation. Accordingly, we recommend that amino acid composition, Gla content and amino acid concentration be measured with the D/L ratio in both the calibration and unknown samples to minimise the possibility of introducing significant errors in the calibration step. In addition to improving the reliability of the racemisation dating method, the routine measurement and reporting of these parameters would, over a period of time, generate a valuable data base for profiling the leaching–racemisation relationship at ambient temperatures.

We thank Dr P. E. Hare for helpful discussions, Mrs P. L. Manley and Mrs C. D. Ernst for technical assistance, and contributors of the samples for their generosity. This work was supported by the NSF. J.L.B. is an Alfred P. Sloan fellow (1975–79).

Origin and palaeoenvironmental interpretation of sarsens

M. A. Summerfield

School of Geography, Mansfield Road, Oxford, UK

No detailed explanation has yet been provided for the origin of sarsens (silicified Cenozoic sediments) which are widely distributed across southern England (Fig. 1). The problem of sarsen formation is related to that of analogous terrestrial siliceous deposits recorded from every continent except Antarctica[1–7]. In addition sarsens are of considerable archaeological interest as they were extensively used in the construction of megalithic monuments, notably those at Avebury and Stonehenge. It has been suggested that sarsens are glacially transported erratics[8,9], although this view has been challenged[10]. Their occurrence in areas in which other evidence of glacial activity is lacking, and the preservation on the surface of some sarsen stones of pockets of very weakly cemented sand, does not concur with the idea of long-distance transportation, but rather suggests local derivation from an original Cenozoic cover. Here the initial formation of sarsens is considered and recognition that they represent silcrete remnants enables broad conclusions to be drawn about their genesis and palaeoenvironmental significance. From macromorphological, micromorphological and chemical comparisons with low latitude silcretes, primarily from southern Africa, it is concluded that sarsens represent remnants of surface and near-surface silicification developed on tectonically stable landsurfaces of minimal local relief. Most sarsens seem to have formed under a semi-arid or arid climate, although there is evidence of development in a relatively humid environment for some occurrences.

As there are no entirely reliable reports of *in situ* sarsen occurrences, field evidence is confined to individual sarsen stones, up to 5 m or more across, found resting on the Chalk and on, or within, Cenozoic sediments. Sarsens range from orthoquartzites to predominantly fine-grained siliceous sediments and silicified conglomerates (Hertfordshire and Bradenham Puddingstones). A surface, or near-surface, origin is indicated by the presence of apparent rootlet channels in many samples and, more rarely, by silicified roots[11]. Sarsens represent various forms of silcrete[12] and consequently their genesis may be elucidated by comparison with the extensive silcrete occurrences of Africa and Australia.

Sarsens are highly siliceous sediments (Table 1). Micromorphologically they can be classified into GS-(grain-supported), F-(floating) and C-(conglomeratic) fabric types[13]. GS-fabric sarsens consist of skeletal framework grains ($>30\ \mu m$ across), almost exclusively of quartz, usually cemented by optically continuous overgrowths, and less frequently by microquartz. F-fabric sarsens are composed of predominantly quartz skeletal grains, floating in a microquartz or cryptocrystalline silica matrix. C-fabric sarsens most commonly consist of flint pebbles in a 'matrix' of the GS-fabric type.

Field investigations of silcretes from southern Africa have shown that a distinction can be made between those occurrences associated with weathering profiles (weathering profile silcretes, WPS), and those that are not (non-weathering profile silcretes, N-WPS). These differences in field occurrence are accompanied by contrasting chemical and micromorphological characteristics. GS-fabrics, C-fabrics, optically continuous overgrowths, chalcedonic overgrowths and chalcedony vugh-fills are absent in WPS while M-(matrix) fabrics ($<5\%$ skeletal grains ($>30\ \mu m$ across)) are abundant (Table 2). In N-WPS authigenic glaebules and colloform features are apparently absent and M-fabrics are rare. WPS are titanium-rich ($TiO_2 > 1\%$) while N-WPS are titanium-poor ($TiO_2 < 0.2\%$) (Table 1). N-WPS are typically

Table 1 Bulk chemical analyses of sarsens and southern African silcretes

Analyses by XRF normalised to 100%. The high mean K_2O content of N-WPS is associated with (glauconite-rich?) green pan silcretes (silicified pan clays). Letters in parentheses refer to sample locations in Fig. 1.

more chemically and micromorphologically variable than WPS as they represent the silicification of a wide variety of host materials including calcretes, fluvial deposits and pan sediments.

In the sarsen samples examined the GS-fabric type (with optically continuous overgrowths) is the most common. F-fabrics are relatively scarce, except locally. Comparative micromorphological evidence from southern African silcretes militates against a weathering profile origin for GS- and C-fabric sarsens (Table 2). The status of F-fabric sarsens is less certain in that the micromorphological and chemical evidence points to a weathering profile origin for at least some occurrences. This is supported by the high titanium content (2.08% TiO_2) (Table 1) of an F-fabric sarsen which is micromorphologically identical to many F-fabric WPS from southern Africa (Fig. 2). The titanium appears to be present in dull brownish aggregates (identified by X-ray diffraction as anatase in southern African silcretes) within the matrix. Titanium- and iron-rich zones as colloform features have also been reported in F-fabric sarsens (K. Isaac, personal communication). Further analyses are required to establish whether F-fabric sarsens are characteristically titanium-rich.

The nature of the host material and of the circulating solutions responsible for silicification are the key factors in influencing sarsen micromorphology. GS-fabric sarsens formed through passive void-filling by overgrowths or microquartz of a quartzose host sediment. The development of optically continuous overgrowths implies a lack of clay within the host sediment[14,15] and circulating solutions characterised by both low concentrations of silica and of other ions (which could disrupt the orderly growth of macro-crystals). Conversely the presence of intergranular clay and of relatively high concentrations of silica and/or 'disruptive' ions would promote microquartz or even cryptocrystalline silica precipitation[16]. A similar interpretation may be applied to C-fabric sarsens as these differ from the GS-fabric type only in the size range of their skeletal grain fraction. F-fabrics can be generated by displacement or partial replacement of skeletal grains or by replacement of the matrix of an F-fabric host material such as clayey weathering deposit containing floating quartz grains. Matrix replacement is the favoured interpretation for sarsens as evidence of marked skeletal grain replacement is lacking and as displacive growth of authigenic quartz within voids is an untenable explanation of F-fabrics with a small skeletal grain component (Fig. 2) because of the considerable volume increase required. In silcretes from southern Africa there is no field evidence for the anticipated macroscale expansion which would be associated with F-fabrics generated by displacive crystal growth (such as there is in some cases for calcretes in the form of pseudoanticlines).

Previous explanations of sarsen formation have focused on macroscale climatic factors and have largely ignored geochemical conditions and micromorphological properties. A capillary rise mechanism has been favoured involving silica mobilisation and surface concentration (due to evaporation) in response to a seasonally dry climate[11]. However, only thin surface crusts (rather than the typically observed short-axis sarsen dimensions of $\sim$1 m) could form in this way as initial surficial silica precipitation would inhibit, and eventually prevent, the upward movement of solutions to the surface.

Comparison with silcretes from southern Africa and Australia

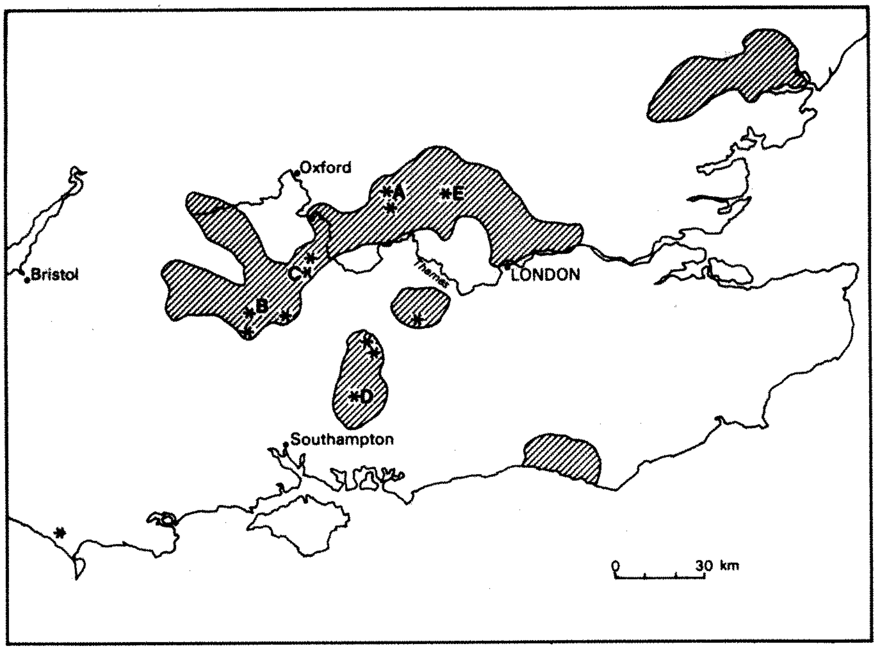

Fig. 1 Distribution of sarsens in southern England. Shaded areas indicate main regions of sarsen concentrations. Sample sites marked by asterisk. For key to letters see Table 1.

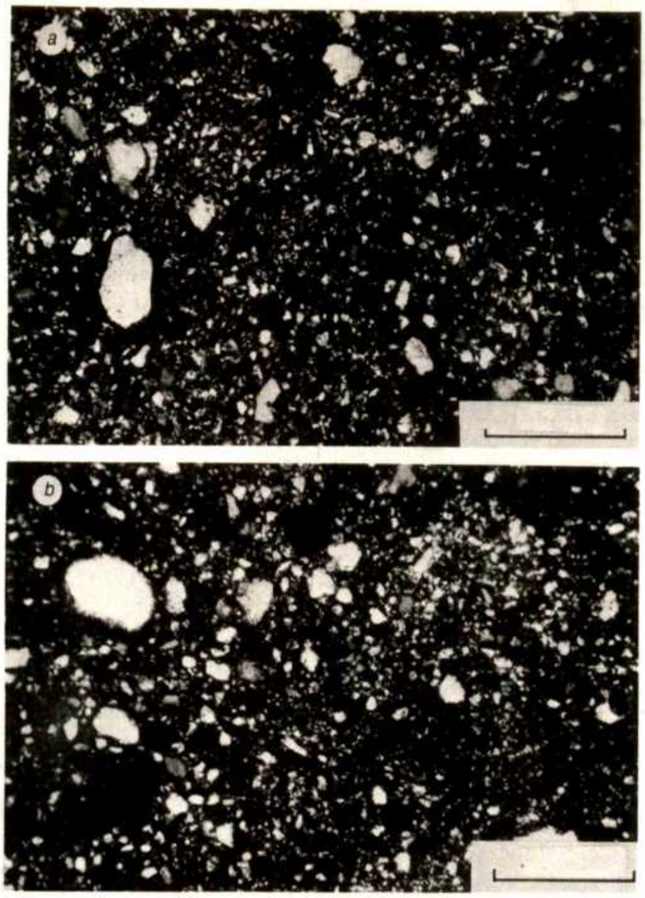

Fig. 2 Photomicrographs of *a*, F-fabric sarsen (sample C in Table 1) and *b*, F-fabric silcrete from Riversdale, South Africa. Both samples have a small skeletal grain fraction and titanium-rich matrix (2.08% TiO_2 in *a*, and 1.72% TiO_2 in *b*). Crossed polarisers. Scale bars, 500 μm.

suggests several possible origins for sarsens. Probable local silica sources for N-WPS include direct dissolution of quartz grains and enhanced solubility quartz particles produced through grain abrasion, and release of silica during calcrete formation or from diatoms and other silica-secreting organisms. Silica may also be supplied from surface waters and atmospheric fall-out. A decrease in *p*H from >9 to <9, is considered to be a probable silica precipitating mechanism. Periodic changes in *p*H produced by dilution by fresh surface waters could produce alternating phases of high silica mobility (*p*H >9) and silica precipitation (*p*H <9). Alternatively, in the absence of *p*H changes, silica may gradually precipitate (particularly as overgrowths) from slowly migrating solutions only moderately supersaturated with respect to quartz. Water table fluctuations and downward percolation are regarded as the most viable models of N-WPS formation as these are the only mechanisms which allow the development of laterally extensive and relatively thick silcrete horizons.

Silica released within the weathering zone, either through bedrock weathering or clay mineral alteration (such as illite → kaolinite) provides the most likely silica source for WPS. Silica so released could become precipitated lower down the profile if drainage were sufficiently restricted. Aluminium mobilisation accompanying silica replacement of weathering profile clays would probably be associated with a low *p*H environment (*p*H <4) and titanium mobility and concentration in WPS supports this idea[13,17].

Table 2 Relative frequency of micromorphological features and fabrics in sarsens, WPS and N-WPS from southern Africa

Micromorphological feature/fabric	Sarsens	N-WPS	WPS
Optically continuous overgrowths	A	U	X
Chalcedonic overgrowths	X	U	X
Glaebules (authigenic)	X	X	A
Colloform features	U	X	A
M-fabric	X	R	A
F-fabric	U	A	A
GS-fabric	A	U	X
C-fabric	C	U	X

A, abundant; C, common; U, uncommon; R, rare; X, absent. No. of samples: sarsens, 18; N-WPS, 29; WPS, 93.

The proposed high *p*H environment and lack of associated deeply weathered sediments suggests a semi-arid or arid climate during N-WPS formation; a similar interpretation is appropriate for GS- and C-fabric sarsens. WPS probably formed under a relatively humid climate where rates of organic activity were sufficiently high to promote a low *p*H environment, and it is likely that titanium-rich F-fabric sarsens formed in similar conditions.

Future investigations of *in situ* sarsen equivalents in France (meulière) and elsewhere in mainland Europe associated with a more complete Cenozoic stratigraphic record should clarify the problem of dating sarsen formation and provide a basis for independent evidence for palaeoclimatic interpretation.

I thank Drs A. S. Goudie and W. B. Whalley for helpful discussions. Dr A. S. Goudie also supplied some of the sarsen samples. Initial project finance was provided by NERC and supplementary finance by the Marico Mineral Co.

Host specificity of temperate and tropical animals

R. A. Beaver

Department of Biology, University of Zambia, P.O. Box 2379, Lusaka, Zambia

Many groups of animals show a gradient of increasing species richness from polar to equatorial regions[1,2]. Theory[3,4] suggests that species should be more specialised ecologically in the tropics. Most of the evidence for this comes from studies on birds[5–10]. Birds appear to subdivide the habitat more finely and specialise more in their food in the tropics. It has been suggested[11] that tropical Papilionidae (Lepidoptera) are more specialised in their hosts than temperate species, but host specificity was considered only at the level of the plant family, and more detailed studies of a wide range of butterflies[12] suggest that they are little (if at all) more specialised in their food plants in the tropics. Similarly, monogenean trematode parasites of fish show no change in the degree of host specificity at different latitudes[13]. Here it is shown that one group of insects, the bark and ambrosia beetles (Coleoptera: Scolytidae and Platypodidae), are less host-specific in the tropics than in temperate regions, even though there are considerably more species present in the tropics. The 'reverse' latitudinal gradient in host specificity can be related to the greater proportion of relatively non-specific xylomycetophagous species (ambrosia beetles) in the tropics and to the greater heterogeneity of tropical forests which will make host specialisation more difficult.

Fiji	18,300	16–19° S	81	81

* No. of species expected in an area the size of Fiji, assuming a linear relationship between log (no. of species) and log (area) with a slope of 0.2–0.35.

Comparisons have been made between the bark and ambrosia beetle faunas of two temperate areas, France[14] and California[15], and two tropical areas, West Malaysia[16,17] and Fiji[18]. The data obtained from refs 14 and 16–18 have been extended and/or updated by reference to many other sources. Table 1 indicates a gradient in species richness from the temperate to the tropical zone when area is taken into account. The islands of Fiji are perhaps no richer in species than California if equal areas are compared, but relatively fewer species are expected in isolated oceanic islands than on the mainland.

The data are classified according to host specificity and feeding habits of the beetles in Table 2. (Terms used to describe the feeding habits are defined in Table 2 legend.) Information on both parameters is available for 98% of the species recorded in the temperate areas, but only 69% in Fiji and 54% in Malaysia. However, my own observations of the fauna of West Malaysia and of other tropical areas suggest that the main conclusions obtained here will not be significantly changed if further information becomes available for the tropical areas.

Errors are possible in the assignment of beetle species to different grades of host specificity. Thus if a host genus is monospecific in an area, or a host family is monogeneric, the true specificity of the beetle may be overestimated. Conversely, some species occasionally attack hosts outside their normal range. Breeding in such hosts may not occur, but the host may still appear in host lists. Errors in assignment are generally likely to overestimate host specificity and to be greater for the tropical areas. Corrections of such errors as more information becomes available will probably increase the observed differences between temperate and tropical areas.

Table 2 Number of species of Scolytidae and Platypodidae with different feeding habits confined to a particular species, genus or family of host plants or polyphagous

* Phloeophagous species construct gallery systems and breed in the phloem and inner bark of woody plants; herbiphagous species in the stems of non-woody plants, in the pith of twigs or in leafstalks; spermatophagous species in seeds and fruits. Xylophagous species live and feed on the wood; xylomycetophagous species usually live in the wood but cultivate and feed on ambrosia fungi growing on the walls of their galleries[19,20].

Table 3 Values of χ^{2*} based on percentages of species of Scolytidae and Platypodidae with different host specificity for pairs of countries

Species group	Countries compared† Fr/Ca	Fr/Ma	Fr/Fi	Ca/Ma	Ca/Fi	Ma/Fi
All	10.5	81.3	74.2	107.4	88.0	15.9
Phloeophagous	10.9	63.9	54.5	91.3	46.0	52.5
Xylomycetophagous	13.0	15.9	8.7	12.8	22.7	7.6

* Values greater than 7.8 are significant at the 5% level; 11.3 at the 1% level.

† Ca, California; Fi, Fiji; Fr, France; Ma, West Malaysia.

The Platypodidae (all xylomycetophagous) have been lumped together with the Scolytidae because (1) they are probably no more than a divergent subfamily of Scolytidae[21]; and (2) the proportions of Platypodidae in the different grades of host specificity in West Malaysia are not significantly different ($\chi^2 = 3.1$) from the proportions found in the xylomycetophagous Scolytidae in that country. The family is only abundant in West Malaysia among the study areas (63 species included in Table 2). It forms a minor part of the fauna of the other areas (one species in California, two in France, five in Fiji).

The results of χ^2 tests carried out on the percentages of phloeophagous and xylomycetophagous species and all species together are shown in Table 3. Numbers of species in the groups with other feeding habits are too low for comparisons to be made. Comparing the total fauna of the four areas, it is clear that the tropical beetles as a whole are far less host specific than those of temperate areas. There is far greater similarity within the tropical or temperate zones than between them. Host specificity is greatest in California and least in Malaysia. One reason for this is apparent from the more detailed analysis. A far higher percentage of the fauna consists of xylomycetophagous species in the tropics. This group shows low host specificity (Table 2). Values of χ^2 are relatively low for all comparisons within this group of species, indicating a similar low specificity in both temperate and tropical regions. The ambrosia fungi, on which both adults and larvae feed, will grow in a great variety of trees. It must be remembered that the beetle, so far as is known, feeds on the same fungi whatever host it is attacking, and it is really the fungi that are polyphagous and not the beetle. However, it is the beetle that selects the host tree.

The host specificity of the phloeophagous species is similar in France and California, and higher than in the tropical countries. The difference is perhaps related to the greater species diversity and heterogeneity of tropical forests. Specialisation is only possible if the resource(s) on which specialisation occurs is renewed in a way that is reasonably regular relative to the dispersive ability and lifespan of the species concerned. Too great a scattering of the resource in space or time and the species can not specialise on it[22]. The beetle–host tree system has two basic characteristics[23]. The first is that the habitat stability[24] of the habitat unit (plant stem, leafstalk, fruit or seed) is approximately unity, so that only one beetle generation is possible in the unit. The second is that habitat units in a suitable state for colonisation form a spatial patchwork in the environment. Since each unit can be colonised for only a limited period, the spatial pattern continually shifts with time. As a result, the beetles are faced in each generation with the problems of relatively long-distance dispersal and host-finding. The problems are greater in tropical than temperate forests because of the higher species diversity and the more rapid processes of decay. In a highly heterogeneous environment, it can be advantageous to evolve strategies that reduce the apparent heterogeneity of the system from the point of view of the individual insect. One such strategy is to increase the degree of polyphagy[23].

The finding that host specificity of phloeophagous species is greater in Fiji than in West Malaysia is also contrary to current thought. Birds on islands tend to have broader habitats and eat more kinds of food than on the mainland[8,25]. For the Fijian beetles, it is useful to distinguish between endemic and introduced species. The former are more host specific than the latter, and tend to be confined to the native forest trees[18]. The introduced species are mostly 'tramp' species which have been transported over wide areas of the tropics and are able to breed in both native and introduced trees. The greater host specificity of the endemic species may be related to the lower diversity of Fijian than Malaysian forests. From the point of view of the beetles, the Fijian forest is less heterogeneous and greater specialisation is possible. The introduced species with broader niches seem likely to gradually displace the endemic specialists[26,27].

The reasons for the low proportion of xylomycetophagous species in temperate areas, and of phloeophagous species in tropical areas are not clear[20]. The ambrosia fungi presumably grow more slowly in colder climates, and the rate of production may be insufficient to keep the beetles and their offspring alive. The number of phloeophagous species in the tropics may be reduced by the greater abundance of Cerambycidae (longhorn beetles), many of which occur in the same niche, and whose larvae act as predators of bark beetle broods. Other factors are doubtless involved.

The data presented above do not support the usual view that species are more specialised in the tropics. Other animal taxa whose essential resources are more scattered in space and/or time in tropical than temperate latitudes may well show 'reverse' latitudinal gradients too. There is so little information available on the host specificity of invertebrates along latitudinal gradients that generalisations are premature.

I am grateful to P. W. Price for his help and encouragement.

Swimming control in a cubomedusan jellyfish

R. A. Satterlie & A. N. Spencer

Department of Zoology, The University of Alberta, Edmonton, Alberta, Canada T6G 2E9

Although it has been established that swimming in scyphozoans is under control of rhopalial pacemakers and an associated subumbrellar nerve-net[1–3], little is known about this control at the cellular level. There is some doubt whether scyphozoan neurones have all-or-none action potentials[3–6]. Here we show that subumbrellar neurones of the sea wasp *Carybdea rastonii* Haacke (Class Scyphozoa, Order Cubomedusae) propagate such action potentials, and that activity in these neurones originates in the rhopalial pacemakers and produces a contraction of the swimming musculature. The neurophysiology of swimming has not previously been studied in this order.

In order to determine the structure of the subumbrellar nerve-net of *Carybdea* we examined both live material and electron micrographs. Bipolar and tripolar neurones form an apparently random network throughout the subumbrella of *Carybdea*. The diameter of neurites ranges from 0.2 to 5 μm while the cell bodies can be up to 40 μm long. Interneural and neuromuscular synapses occur throughout the subumbrellar nerve-net.

Pacemaker activity is restricted to the rhopalia since jellyfish stopped swimming when we removed the rhopalia. When suction electrodes were attached to a rhopalium and to an adjacent region of the subumbrella, motor impulses originating in the rhopalium and conducted into the subumbrellar nerve-net were recorded. Potentials recorded over the nerve-ring during swimming consisted of two distinct components; a rapid (<10 ms) invariable biphasic spike, up to 80 μV, and a complex multiphasic spike of variable amplitude and duration (Fig. 1*a*). Changes in amplitude of the second component were associated with variations in the magnitude of muscular contractions (Fig. 1*b*). Therefore, we interpret the two components as an initial nerve spike followed by a compound muscle potential. As the interpulse interval of pacemaker spikes decreases, the amplitude of muscle potentials and contractions increases, suggesting neuroeffector facilitation. Excess Mg^{2+} (1:1 solution of

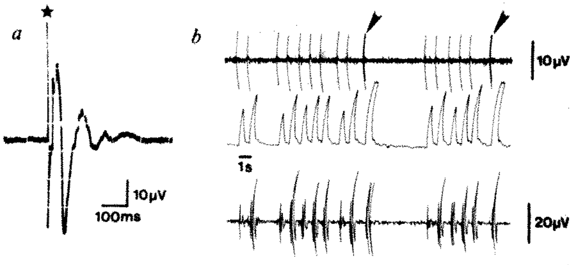

Fig. 1 *a*, An extracellular suction electrode covering the nerve-ring and surrounding subumbrellar muscle records a single, spontaneous swimming contraction. The rapid biphasic nerve spike (★) is followed by a complex muscle potential. *b*, Extracellular recordings from a rhopalial pacemaker site (top trace) and the nerve-ring of the opposite bell quadrant (bottom trace). An uncalibrated force transducer record shows circular muscle contractions at a point midway between the two electrodes (middle trace). The amplitude of the muscle contractions can be roughly correlated with the size of the compound muscle potentials of the bottom trace. Two double pacemaker spikes (arrows) give rise to double muscle potentials and a far larger contraction.

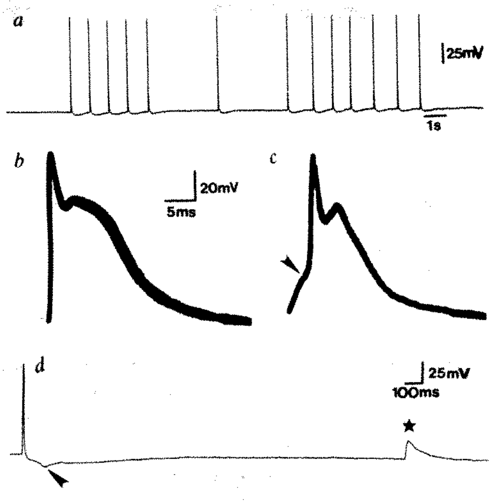

Fig. 2 *a*, Spontaneous intracellular action potentials from a subumbrellar motoneurone soma initiating 13 swimming contractions. Note the flat resting potential and the hyperpolarisations which follow each spike, *b*, Six superimposed action potentials from a motoneurone soma. In any one recording, there is little variation in the shape of the spike. *c*, The rapid depolarisation of a neuronal action potential was frequently superimposed on an apparent synaptic event (arrow). Similar synaptic events were occasionally recorded alone (*d*, ★). The notch seen in the spike after-hyperpolarisation (*d*, arrow) is a movement artefact caused by contraction of the surrounding muscles. d.c. amplification was used with 20–60 MΩ, 3 M KCl filled micropipette electrodes. The subumbrellar muscle sheet was dissected from one quadrant of the animal and pinned to a Sylgard base. A small circle of pins surrounded the penetrated neurone soma, which was visible with oblique substage illumination.

0.37 M $MgCl_2$: seawater) in the bath blocked muscular contractions within 5 min. This was followed by total cessation of all recordable electrical activity.

Cell bodies of bipolar and tripolar subumbrellar neurones gave stable recording for up to 15 min, when impaled with glass microelectrodes filled with 3 M KCl. Negative resting potentials of 72–76 mV were interrupted by all-or-none, positive-going action potentials of 105–120 mV and 12–20 ms duration (Fig. 2*a*, *b*). The slow membrane potential oscillations that have been recorded from the 'giant' neurones of hydromedusae[7,8] were not seen. Action potentials consisted of a rapid rise to peak amplitude (1–2 ms risetime) and a slow partial decay with a second rounded peak (Fig. 2*b*, *c*). The action potential was followed by a 700–800 ms, 3–15 mV after-hyperpolarisation (Fig. 2*a*). In all but one record, in which a poor penetration was suspected, little variation in the shape of the action potential was evident during repetitive activity (Fig. 2*b*). In particular, the second peak did not vary with the strength of muscular contractions. The initial rise of many spikes was superimposed on a small 10–30 mV pre-potential (Fig. 2*c*). Occasionally similar depolarisations (200–300 ms duration) were recorded which did not trigger action potentials (Fig. 2*d*). We presume that these small amplitude events represent excitatory synaptic input from adjoining neurones of the net. Each action potential preceded a muscular contraction of the surrounding subumbrellar sheet, as judged by visual observation. Only occasionally were contractions not accompanied by spikes in the impaled neurone. In these instances, a conduction block was suspected, owing to the extensive pinning required to minimise movement near the electrode.

Those properties of the neuromuscular system of *Carybdea* which most clearly show it to be of the scyphozoan type are as follows. First, if the rhopalia, containing the pacemakers, are removed then there is no activity in the subumbrellar nerve-net and swimming ceases. Second, the flat resting potential (absence of pacemaker potentials) of subumbrellar neurones, together with the observation that action potentials in these cells seem to be driven by excitatory synaptic potentials, suggest that the subumbrellar neurones are not autorhythmic but merely pass the motor pattern on to neighbouring cells of the net. These neurones function as both interneurones and motorneurones since spiking in subumbrellar neurones is associated with contractions of the underlying musculature.

Intracellular and extracellular electrophysiological recordings indicate that information in the subumbrellar nerve-net of *Carybdea*, and possibly other scyphozoans[4,5], is frequency coded with all-or-none impulses. The neuromuscular characteristics of swimming in *Carybdea*, described here, indicate that the Cubomedusae are closely related to other scyphozoans. This conclusion may be significant since the systematic position of cubomedusae has recently been questioned[9].

All-or-none action potentials were recorded recently by Schwab in the subumbrellar neurones of another scyphozoan, *Cyanea* (personal communication).

Part of this work was completed in the laboratory of Dr J. F. Case, University of California, Santa Barbara, and supported by the US Office of Naval Research contract N00014-75-C-0242. Additional support came from NSERC (Canada) Grant A0419 to A.N.S. We thank Shane Anderson and Gary Robinson for collecting the jellyfish.

Fast and slow myosin within single skeletal muscle fibres of adult rabbits

H. Lutz, H. Weber, R. Billeter & E. Jenny

Institut für Pharmakologie und Biochemie der Universität Zürich,
Winterhurerstr. 260, CH-8057 Zürich, Switzerland

There is good evidence for the coexistence of different myosin types both in developing muscles[1–3] and in Purkinje cells from adult chicken hearts[4]. In skeletal muscle fibres of adult animals, however, coexistence of fast (FM) and slow (SM) myosin has only been demonstrated after long-term electrical stimulation[5,6]. The term 'promiscuity' has recently been coined[7] to describe the coexistence of different myosin isoenzymes within a single fibre. Using novel, refined immunological methods we demonstrate here the presence of both FM and SM within single fibres of the musculus tibialis anterior of adult rabbits. Essentially identical results were also obtained with other muscles. Our findings imply that the genes coding for FM and SM can be expressed simultaneously within the same cell throughout an animal's entire life, and not only during development or after artificial electrical stimulation.

To test for the presence of FM and SM, antibodies of high specificity and high affinity[8] were raised against rabbit FM, SM and the light chains of rabbit cardiac myosin[9,10]. These antibodies were used in two types of assay. First, immunohistochemistry for myosin was performed on sections of shock-frozen muscle pieces and the reaction monitored by histochemical photometry. In addition, conventional histochemistry for myosin-ATPase[11], NADH-tetrazolium reductase[12] and phosphorylase[13] allowed the fibres to be classified into fibre types[11,14]. Combining the nomenclatures proposed by Brooke and Kaiser[11] and Peter *et al.*[14], the fibres were designated as type I (slow-twitch-oxidative), type IIA (fast-twitch-oxidative-glycolytic), type IIB (fast-twitch-glycolytic) and type IIC (the very

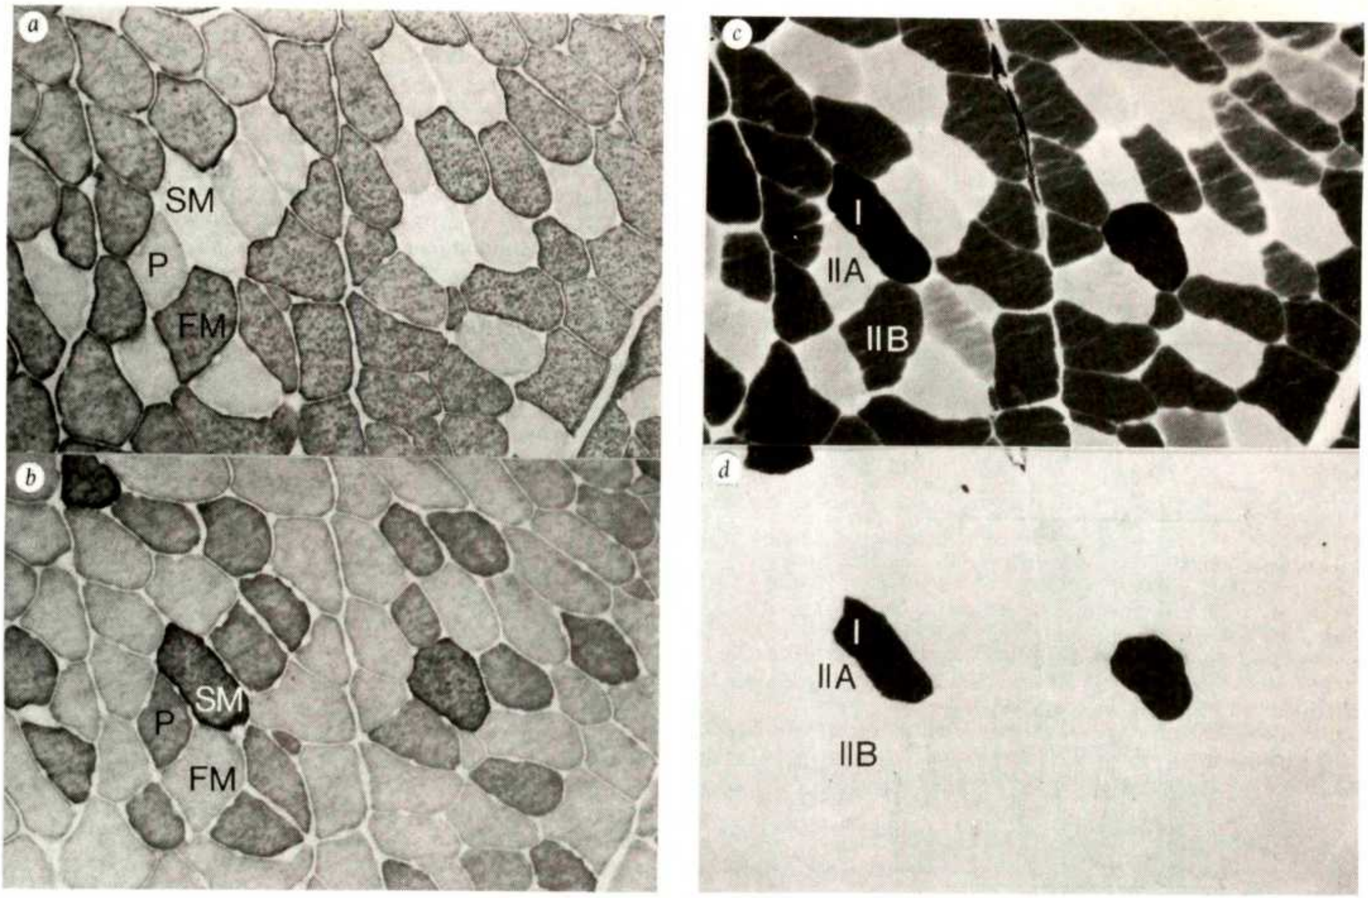

Fig. 1 Successive serial transverse sections of the musculus tibialis anterior of an adult (18 months old) rabbit analysed for FM (*a*), SM (*b*) and histochemical fibre type (*c*, *d*). Antibodies of high affinity and low heterogeneity were induced in high-responder guinea pigs using a long-term, low-dose immunisation programme[8] and their specificities demonstrated as described[9]. Antibodies against the light chains of rabbit cardiac myosin were also prepared[10] and analysed in the same way. Cryostat sections (8–10 μm) of shock-frozen muscle pieces were reacted with antibody and the immuno-complexes visualised using a protein A-peroxidase technique optimised for our needs[18]. *a*, Reaction with anti-FM serum. *b*, Reaction with anti-SM serum; the same staining pattern was obtained with anti-cardiac-light-chain sera shown to cross-react strongly with the two light chains of SM but only negligibly with those of FM (Fig. 3*a*, *b*). *c*, *d* Staining for myosin-ATPase[11] after preincubation at *p*H 4.6 or 4.35, respectively, for 5 min as a means of classifying fibres into types I, IIA, IIB and IIC; identical results were obtained when staining was for NADH-tetrazolium reductase[12] and phosphorylase[13] (data not shown). Note that some fibres, one of them marked P (promiscuous), react with both antisera (*a*, *b*); histochemically they belong to type IIA (*c*). ×150.

rare type IIC fibres have been designated as undifferentiated fibres[15]). Second, myosin light chains from dissociated muscle tissue were analysed by combining classical gel electrophoresis[16] with subsequent assay of the separated proteins by an enzyme-linked-immunosorbent-assay (ELISA) technique[9].

When serial sections of the anterior tibial muscle were reacted with sera raised against FM (Fig. 1*a*) or SM (Fig. 1*b*) and the fibres histochemically typed (Fig. 1*c*, *d*), a clear correspondence of the staining patterns emerged. Type I fibres reacted with anti-SM sera only and type IIB fibres with anti-FM sera only. In contrast, type IIA fibres reacted with both antisera, as did the rarely occurring type IIC fibres. Close examination of the staining intensities of type IIA (P) fibres (Fig. 1, *a*–*c*) indicated the existence of subpopulations containing varying proportions of FM and SM. Computer-assisted analysis of the staining intensities of 132 randomly chosen fibres reacted with anti-FM and anti-SM sera revealed three well separated clusters (Fig. 2) corresponding to fibres containing only SM (7.3% of all fibres), only FM (61.4%) or both SM and FM in varying proportions (31.3%). Our results agree with those of Spamer and Pette[17], who presented evidence suggesting the existence of subpopulations of type II fibres having a wide range of aerobic oxidative capacities and differences in their ability to oxidise fatty acids.

To confirm the presence of SM within type II fibres, 10 serial 40-μm sections of the anterior tibial muscle were selected for absence of type I fibres. Following dissociation, the released proteins were separated by gel electrophoresis and analysed

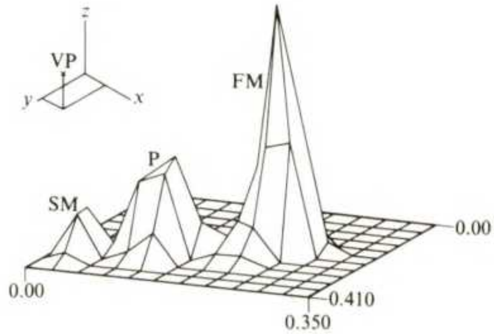

Fig. 2 Computer-assisted analysis of the FM and SM contents of 132 randomly chosen fibres from the anterior tibial muscle of an adult (18 months old) rabbit. Two successive transverse cryostat sections (8–10 μm) were reacted with anti-FM or anti-SM, respectively, and developed using a protein A-peroxidase technique[18]. Protein A binds to the Fc portion of immunoglobulins (IgG) and the covalently attached peroxidase thus allows detection of antigenic sites. The absorbance of each fibre was measured (Leitz microscope photometer MPV 2), computed and plotted to give a relative frequency distribution. *x*, Absorbance after reaction with anti-FM serum. *y*, Absorbance after reaction with anti-SM serum. *z*, Relative frequency of absorbance values. VP, computer adjusted viewpoint for optimal three-dimensional impression. P, fibres containing both FM and SM; the width of this peak suggests the presence of subpopulations of fibres containing varying proportions of FM and SM.

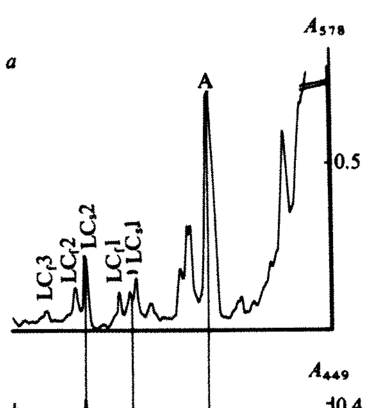

Fig. 3 Analysis of myosin light chains by a combination of 12% polyacrylamide gel electrophoresis and ELISA. *a*, Densitogram of gel stained with Coomassie brilliant blue after electrophoresis[16] of an artificial test mixture obtained from dissociated (5 min at 98 °C in SDS sample buffer) myofibrils of fast and slow twitch fibres (~20 μg of protein each). *b*, Immunoreaction of the same proteins as in *a*: proteins were eluted from slices (1 mm segments) of a parallel gel, reacted with antiserum (dilution 1:100) raised against the light chains of rabbit cardiac myosin and assayed by an ELISA technique[9]; this antiserum reacted negligibly with light chains from FM alone but gave a trace identical to the one shown here with light chains from SM alone (not shown); anti-SM sera were not used in this assay as they only recognise LC$_s$1 (ref. 9). *c*, Densitoram of gel stained with Coomassie brilliant blue after electrophoresis of total proteins from selected segments of anterior tibial muscle (adult rabbit, 18 months old); shock-frozen muscle pieces were serially sectioned (40 μm), the fibres typed histochemcally in every fifth section, and 10 intervening sections chosen for absence of type I fibres; the sections were dissociated as in *a* and the proteins analysed by electrophoresis. *d*, Immunoreaction of the same proteins as in *c* separated on a parallel gel and analysed by an ELISA technique[9] (serum dilution 1:75) as in *b*. Densitograms in *a* and *c* were aligned with respect to actin. A, actin; LC$_f$1, LC$_f$2 and LC$_f$3, light chains of FM; LC$_s$1 and LC$_s$2, light chains of SM.

using an antiserum directed against the light chains of SM (Fig. 3*a*, *b*). This revealed two main peaks corresponding exactly to the positions of the two light chains of SM (Fig. 3*c*, *d*). This result supports the view that type II fibres also contain SM. However, identification of the SM-containing subtype(s), for example types IIA, IIB or IIC, was not possible.

There is already evidence that fibres contain both FM and SM. In rat diaphragm, Gauthier *et al.*[1] occasionally detected fibres reacting with both anti-FM and anti-SM sera. In the anterior tibial muscle of rabbits we[9] and Gröschel-Stewart[19] found three populations of fibres, one of them giving an intermediate reaction with antibodies raised against either human pectoral muscle actomyosin or rabbit FM, respectively. In addition, reciprocal transformations of fibre types occurred in rats[20] and humans[21] depending on physical activity, suggesting a profound change in the proportions of myosin isoenzymes. However, in histochemically identified single fibres of adult rabbit skeletal muscles, Weeds *et al.*[22] and Pette and Schnez[23] could only demonstrate the presence of either FM or SM by microgel electrophoresis. Rubinstein *et al.*[6] did not find fibres staining with anti-FM and anti-SM sera by direct immunofluorescence. These seemingly contradictory results can be explained if we consider the sensitivities of the methods used. We believe that a suitable sensitive immunological method can detect a smaller amount of one myosin species in a mixture of two than microgel electrophoresis of isolated single muscle fibres[22,23]. The direct immunofluorescence technique[6] has its well known limitations; we found that the more sensitive indirect immunofluorescence method was insufficient to detect unambiguously the presence of fibres containing both FM and SM[9]. From this we conclude that, in general, type IIA fibres probably contain very small amounts of SM.

An alternative explanation of our results could be the occurrence, in fibres reacting with both FM and SM antisera, of a hybrid myosin consisting of FM heavy chains and SM light chains. Such an hypothetical hybrid in adult muscles has been proposed by Hoh[24]. Hybrids in developing muscles have been suggested by Rubinstein *et al.*[2] and by Pette *et al.*[25].

The results reported here demonstrate that the presence of FM and SM within single muscle fibres of adult animals occurs naturally. Weeds[7] has recently pointed out that isoenzymes of myosin should provide useful markers for unravelling the early events in myogenesis and the differentiation of muscle fibres following innervation. In view of our recent observation that the myosin composition of muscle fibres changes with physical training (R.B., unpublished observation) and during ageing[26], we may add that the analysis of myosin isoenzyme composition could help in understanding the plasticity of muscle throughout life.

Since submission of this manuscript the presence of FM and SM within single fibres of adult rat soleus muscle has been demonstrated[27].

We thank Drs C. C. Kuenzle, C. Heizmann and N. Gitzelmann for reading the manuscript, Mr W. Roemer for technical assistance, Dr H. Fey for a gift of protein A peroxidase and the Contraves AG for support (computer facilities).

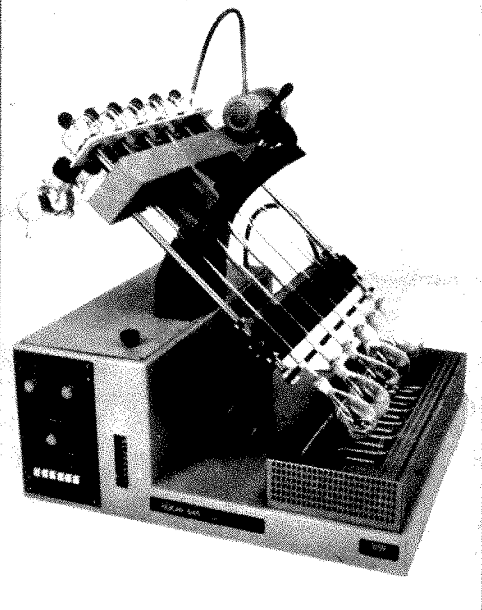
System for trace elements analyses

The BÜCHI Digestor 445 sets new standards in sample preparation!

Convincing advantages

- fully automated system for the digestion of large samples
- sample weight up to 30 g
- simultaneous digestion (ashing) of 6 samples in quartz-glass flasks
- small quantities of reagents – no contamination
- no loss of trace elements during digestion
- high reproduceability
- sealed fume exhaust unit
- stepless regulation of the digestion temperature between 150–400°C.
- salt bath – safe and clean operation
- cooling system for exhaust tubes
- rotation of flasks



We are interested on your Digestor 445.
Please send us your detailed information.

'Square arrays' in the sarcolemma of human skeletal muscle fibres

H. Schmalbruch

Institute of Neurophysiology, University of Copenhagen,
Copenhagen, Denmark

Fast twitch fibres of rat[1] and rabbit[2] show rectangular patterns of intramembrane particles in freeze-fracture preparations of the sarcolemma. These 'square arrays' are almost totally absent in the slow twitch soleus muscle of rat[1]. I report here differences in the incidence of square arrays in human fetal and adult muscle and in different fibres within a human muscle. Square arrays probably classify fast and slow twitch fibres in freeze-fracture preparations of mixed muscles.

A fetal brachial biceps muscle was obtained from a male fetus weighing 385 g (20–24th week of gestation). Surgical biopsies were taken from the medial vastus muscle of two normal male subjects 29 and 36 yr old; the site of biopsy was close to the motor point. Specimens fixed in 2.5% glutaraldehyde were fractured at −100 °C in a Balzers BAE 120 unit and replicated without etching.

Square arrays were found in all fibres from adult muscles but in none of the fetal muscle fibres. The arrays consisted of particles, 6–7 nm in diameter, attached to the P-face of the plasma membrane (Fig. 1); the E-face showed corresponding pits. In some fibres square arrays occurred in clusters and the individual arrays might contain up to 60 particles, whereas in other fibres arrays were dispersed randomly and rarely contained more than 20 particles. The numbers of square arrays per μm² plasma membrane determined in individual fibres formed a two-peak histogram; in fibres in which square arrays occurred frequently the individual arrays were larger than in fibres in which square arrays were rare (Fig. 2).

Thus, the frequency and size of square arrays of the plasma membrane of adult muscle fibres in man identify two classes of fibres; both are different from fetal muscle fibres. This was not due to the fact that junctional and non-junctional parts of the membrane were compared, because none of the preparations contained endplates. From the findings in fast and slow twitch muscles in rat[1] I conclude that the fibres with large square arrays that constitute the right peak of the histogram (Fig. 2) are fast twitch fibres and that those with smaller arrays that constitute the left peak are slow twitch fibres. This difference is less obvious than in rat muscles, where fast twitch fibres display 5–15 square arrays per μm² and slow twitch fibres almost none[1]. The fraction of fibres that were presumably fast (29 of 51, Table 1) agrees with the percentage of fibres that in frozen sections stained intensely for ATPase at *p*H 9.4 (52% and 57%, respectively). In normal mature muscle an intense reaction is thought to identify fast twitch fibres. In the fetal muscle studied all fibres reacted uniformly with quite high intensity.

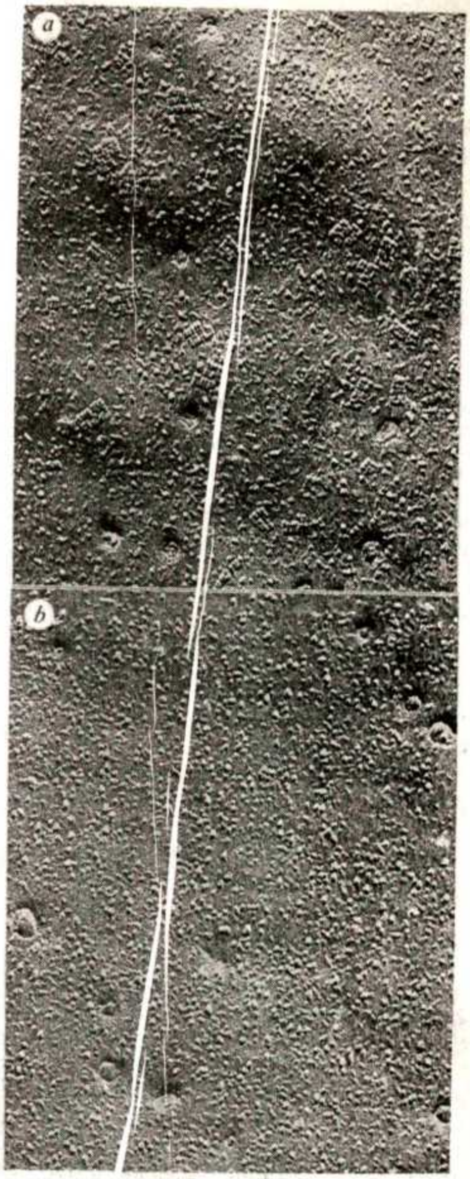

Fig. 1 Freeze-fractures of the medial vastus muscle of man. Both micrographs were taken from the same preparation, the direction of shadowing is from below. The P-faces of the sarcolemma of presumed fast twitch (*a*) and slow twitch (*b*) fibres are shown. Note the many orthogonal arrays of particles in *a* which are absent in *b*. Of each fibre, 22 μm² of the plasma membrane was studied; the number of square arrays was 11.1 per μm² and 1.3 per μm² in the fibres shown in *a* and *b*, respectively. Particles not contained in square arrays vary in diameter. The shallow invaginations represent openings of T-tubules or of caveolae of the plasma membrane. (×72,000).

Table 1 Quantitative findings in the P-face of the sarcolemma of human muscle fibres

	Adult muscle		Fetal muscle	Final magnification of micrographs
	Presumed fast twitch fibres	Presumed slow twitch fibres		
Square arrays per μm² mean (s.d.; *n* fibres)	5.9(3.07; 29)	1.3(0.85; 22)	—	×60,000
Intramembrane particles not in square arrays				
Particles per μm²	949	909	929	×400,000
Size (nm) mean (s,d,; *n* particles	9.7(1.9; 247)	9.4(1.3; 237)	10.5(2.4; 223)	×400,000
Caveolae per μm² mean (s.d.; *n* micrographs)	11.6(4.4; 40)	15.5(7.2; 32)	7.1(3.3; 10)	×60,000

In adult muscles, fibres were classified as presumably fast or slow twitch by size and arrangement of square arrays (unhatched and hatched areas in Fig. 2).

Intramembrane particles attached to the cytoplasmic fracture face (P-face) but not contained in square arrays had the same diameter and were similar in number in fetal and adult and in fast and slow twitch fibres (Table 1). The differences in size were at most 1 nm and thus well below the resolution and reproducibility of the method. The number of this sort of intramembrane particles was higher (900 per μm²) than in previous studies (250 per μm²)[3–5]. In these studies, particles were counted at low magnification (×60,000)[4,5] and small particles may have been

0028–0836/79/370145—02$01.00

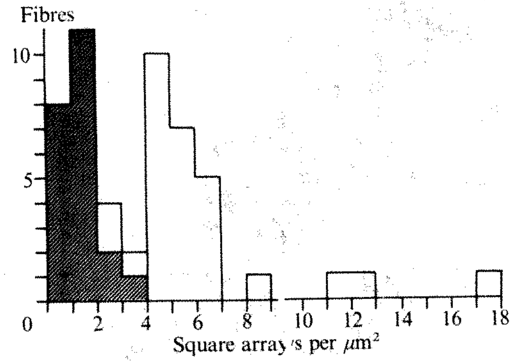

Fig. 2 Histogram of the frequencies of square arrays in 51 randomly selected fibres. Of each fibre, 22 μm^2 of the P-face of the sarcolemma was investigated. The hatched area represents fibres with small and scattered square arrays, the unhatched area represents fibres with large and clustered square arrays.

overlooked. The size was not measured. Although it is possible that some intramembrane particles are artefacts due to condensation of water before shadowing, it is unlikely that the discrepancy is due to the fact that condensation of water was more pronounced in this than in the previous studies.

In rat soleus muscles cross-innervated by a nerve to a fast muscle, square arrays become more frequent; denervation alone does not change the number of square arrays[6]. As cross-innervation changes the contractile properties and the type of myosin[7], this might suggest that innervation exerts a coordinated control of membrane and cytoplasmic aspects of muscle differentiation. Nevertheless, it is unlikely that the type of myosin and number of square arrays are determined by the same factor because fetal muscle fibres that lack square arrays contain a type of myosin that corresponds to myosin in fast twitch fibres of adult muscle[8-12].

There is evidence that intramembrane particles are proteins that, at least partly, determine the physiological properties of the plasma membrane; these properties differ in mature and immature and in fast and slow twitch fibres[13-19]. The number and size of particles not contained in square arrays were the same in the three sorts of fibres studied. This indicates either that square arrays, that is, the unknown protein constituting the particles within these arrays, determine specific properties of the membrane, or that structural differences of particles not contained in square arrays were too small to be demonstrated.

To speculate on the function of square arrays requires a comparison of findings in different species. Structures resembling square arrays are abundant in astrocyte membranes rich in ($Na^+ + K^+$)ATPase; hence, it has been suggested that the number of arrays is related to the activity of this enzyme in muscle fibres[1]. The activity of ($Na^+ + K^+$)ATPase, however, is the same in plasma membranes of fast and slow twitch fibres[20]. One could relate square arrays to a particular type of sodium channel, because only in mature, not immature, muscle fibres are action potentials blocked by tetrodotoxin[18]. Finally, one might consider the distribution of acetylcholine receptors, which is related strictly inversely to that of square arrays: in immature fibres, receptors are randomly distributed and square arrays are absent[15], in fast twitch fibres, receptors are concentrated in the endplate region[21] and square arrays occur everywhere except in the endplate region[1], and in slow twitch fibre some receptors also occur in the extra-junctional membrane[15] where square arrays are less frequent than in fast twitch fibres.

The work was supported by the Danish MRC. I thank Mrs M. Bjærg for technical assistance.

Use of chlorotetracycline fluorescence to demonstrate Ca^{2+}-induced release of Ca^{2+} from the sarcoplasmic reticulum of skinned cardiac cells

Alexandre Fabiato & Françoise Fabiato

Department of Physiology, Medical College of Virginia, Richmond, Virginia 23298

It has been proposed that the trans-sarcolemmal influx of Ca^{2+} occurring during the plateau of the mammalian cardiac action potential is insufficient in itself to activate the myofilaments, but can trigger a release of Ca^{2+} from the sarcoplasmic reticulum (SR) which is sufficient for activation[1]. The demonstration of this Ca^{2+}-induced release of Ca^{2+} relied entirely on experiments in which the tension developed by the myofilaments was used as a sensor of the changes of myoplasmic free Ca^{2+} concentration ([free Ca^{2+}]) in segments of single cardiac cells from which the sarcolemma had been removed by microdissection (skinned cardiac cells)[1]. The small size of these preparations has previously prevented the use of more direct methods for the detection of myoplasmic Ca^{2+} movements[2-4]. The present study is a direct demonstration of Ca^{2+}-induced release of Ca^{2+} from the SR of skinned cardiac cells treated with chlorotetracycline (CTC), a fluorescent chelate probe which enables changes in the amount of Ca^{2+} bound to a variety of biological membranes or micelles to be monitored[5-8]. The fluorescence increases when more Ca^{2+} is bound.

Skinned cardiac cells, 10 μm wide and 50 μm long, from the rat ventricle were prepared as described previously[1]. It was essential to limit the duration and intensity of illumination used for fluorescence excitation so as to avoid a progressive deterioration of the Ca^{2+} accumulation in and release from the SR. Microdissection and attachment of the skinned cell to the microtools were carried out using the regular low-voltage transmitted light of the Biovert inverted microscope (Reichert). Then, in the absence of any illumination, the skinned cell was superfused for 10 min with 5.0×10^{-5} M CTC in a solution containing 3.2×10^{-8} M free Ca^{2+} and 3.2×10^{-4} M free Mg^{2+}, at pH 7.10 and 22 °C. To eliminate any contractile movement during Ca^{2+} release from the SR which would have disturbed the optical recording, a high concentration (1.0×10^{-3} M) of EGTA was used in all the solutions. The [free Ca^{2+}] of 3.2×10^{-8} M has been shown to result in only slightly less than optimal Ca^{2+} loading of the SR[9]. The cell was then washed for 5.0 s in the same Ca^{2+}-containing solution but in the absence of CTC. Only at this time was the shutter open; the fluorescence was excited with the incident illumination of the Biovert microscope through an interference filter (with peak transmission at 400 nm and a bandwidth of 4 nm at half height), a heat absorption filter and an exciter filter. The fluorescence emission was collected with a

0028-0836/79/370146—03$01.00

×60 objective (0.90 n.a.) through a monochromator adjusted at 530 nm, and was measured with a photomultiplier as part of a modified high-sensitivity Reichert microspectrophotometer.

When the perfusion containing 3.2×10^{-8} M free Ca^{2+} was replaced by one with 1.8×10^{-7} M free Ca^{2+}, there was a rapid decrease in fluorescence (Fig. 1*a*). Perfusion with 1.0×10^{-8} M free Ca^{2+} caused a slight increase in fluorescence, and 3.2×10^{-8} M free Ca^{2+} a larger fluorescence. In contrast, a further increase in [free Ca^{2+}] to 1.8×10^{-7} M caused an abrupt decrease in fluorescence.

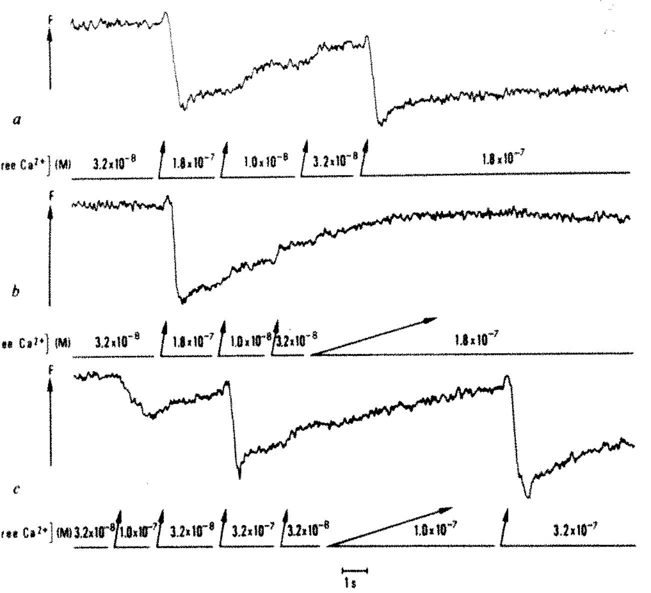

Fig. 1 Effects of varying the myoplasmic [free Ca^{2+}] in skinned cardiac cells on the fluorescence of chlorotetracycline (US Biochemical Corporation). The arrow labelled F at the left of each tracing indicates an increase in fluorescence and the size of the arrow corresponds to 5% of the fluorescence measured during the initial perfusion with 3.2×10^{-8} M free Ca^{2+} (measurement done during a 1.0-s opening of the shutter, not shown). The arrows below each tracing indicate the time and rate of the solution changes. A slow variation of the [free Ca^{2+}] between two values was obtained by varying the relative output of two simultaneous perfusions with two solutions of [free Ca^{2+}] equal to the initial and terminal values, respectively. The perfusion solutions contained 1.0×10^{-3} M total EGTA, 3.2×10^{-3} M Mg-ATP, 3.2×10^{-4} M free Mg^{2+}, 1.5×10^{-2} M creatine phosphate, 15 U ml^{-1} creatine phosphokinase, 0.160 M ionic strength with K^+ and Cl^- as major ions, and 1.0×10^{-1} M sucrose. The *p*H was maintained at 7.10 with 3.0×10^{-2} M *N*-tris(hydroxylmethyl)methyl-2-aminoethanesulphonic acid (TES), which is sufficient for *p*H buffering during Ca^{2+} release from the SR of skinned cardiac cells[9]. The stability constants and the computer program used in the calculation of the multiple equilibria between metals and ligands have been reported in detail elsewhere[9]. In particular, the stability constant described by Allen and Blinks was used for the Ca–EGTA complex (see ref. 9 for refs and correspondence to other stability constants). An apparent stability constant of 7.53×10^2 M^{-1} from the Ca–CTC complex was included in the computer program although this binding is much smaller than the binding of EGTA to Ca. Experiments similar to that of *a* except that the 5.0 s washing and the increase in [free Ca^{2+}] from 3.2×10^{-8} M to 1.8×10^{-7} M were applied at various intervals after the beginning of the CTC-containing perfusion (and experiments using caffeine for inducing a fluorescence decrease) demonstrated that the mean value of the half-time of the CTC perfusion necessary to obtain a maximum amplitude of transient decrease of fluorescence was 176 s. During a continuous perfusion with 3.2×10^{-8} M free Ca^{2+} in the absence of the CTC, there was a progressive decrease in the amplitude of the transient fluorescence decrease. The half-time for this decrease was 142 s when the preparation was illuminated by opening the shutter only at the time of the increase of the [free Ca^{2+}] to 1.8×10^{-7} M. The consistency between the half-times for the increase (176 s) and decrease (142 s) in the amplitude of the fluorescence transient suggests that the decrease was mainly caused by a progressive leakage of CTC from the SR. Additional mechanisms such as a weak Ca^{2+}-ionophoretic effect of CTC[17] could have a minor role. However, during continuous illumination the amplitude of the fluorescence transient decreased much faster because of photodynamic damage to the Ca^{2+} accumlation in and release from the SR. Accordingly, conclusions were derived only from experiments in which, as in *c*, the amplitude of the transient was larger during the second triggering than during the first one. The findings would have been even more dramatic if corrections for the progressive deterioration had been made. Finally, the simplest explanation for the small and transient increase in fluorescence that preceded the Ca^{2+}-induced decrease is to attribute it to the effect of reaching myoplasmic [free Ca^{2+}] values itermediary between 3.2×10^{-8} M and 1.8×10^{-7} M during the time required for perfusion change (0.2 s). This would explain the finding that the fluorescence increased further until a [free Ca^{2+}] sufficient to trigger Ca^{2+} release had been reached.

Although CTC binds to Mg^{2+} as well as to Ca^{2+}, the wavelength of 400 nm selected for excitation favoured the fluorescence of the Ca^{2+} chelate over that of the Mg^{2+} chelate. When excitation was at wavelength 375 nm, which favours the Mg^{2+} chelate, the same increase in [free Ca^{2+}] from 3.2×10^{-8} M to 1.8×10^{-7} M produced a decrease in fluorescence of less than 1% of the maximum fluorescence (defined in Fig. 1 legend). In contrast, a decrease of [free Mg^{2+}] from 3.2×10^{-4} M to 3.2×10^{-5} M, in the presence of a constant [free Ca^{2+}] at 3.2×10^{-8} M, produced a fluorescence decrease of 3% and 14% at excitation wavelengths of 400 and 375 nm respectively. Thus, the changes of fluorescence shown in Fig. 1*a* directly monitored changes in the amount of bound Ca^{2+}, rather than changes in the amount of bound Mg^{2+} resulting from the Ca^{2+} translocation.

The changes in fluorescence intensity (Fig. 1*a*) did not correspond to changes in the amount of Ca^{2+} bound to the mitochondria because results similar to those shown in Fig. 1*a* were obtained in skinned cardiac cells treated with 5.0×10^{-3} M azide or 5.0×10^{-6} M carbonyl cyanide *p*-trifluoromethoxyphenylhydrazone, which should inhibit the energy-linked Ca^{2+} transport by the mitochondria[10], or in cells treated with 1.0×10^{-6} M ruthenium red, which should inhibit passive Ca^{2+} binding to the mitochondria[10]. These findings are consistent with previous results from tension recordings in skinned cardiac cells suggesting that the mitochondria do not interfere with either the active transport or the passive binding of Ca^{2+} when the myoplasmic [free Ca^{2+}] is lower than 1.0×10^{-6} M (refs 1, 9). Furthermore, the classical data supporting the evidence that isolated mitochondria present high-affinity binding sites for Ca^{2+} effective at concentrations lower than 1.0×10^{-6} M have recently been claimed to be artefactual[11,12]. A rapid decrease in fluorescence similar to that shown in Fig. 1*a* could be induced by 1.0×10^{-2} M caffeine or 1.0×10^{-5} M of the ionophore A23187. Both interventions release Ca^{2+} from the SR[9]. The amplitude of the fluorescence decrease induced by increasing the [free Ca^{2+}] was about half of that induced by caffeine and one-quarter of that induced by A23187. In contrast, no decrease in fluorescence was induced by either increasing the [free Ca^{2+}] or adding caffeine or ionophore in cells treated with 0.5% of the detergent Brij 58, which destroys the ability of the SR actively to accumulate and release Ca^{2+} (refs 1, 9). Accordingly, the transient changes in fluorescence intensity (Fig. 1*a*) were entirely attributed to changes in the amount of Ca^{2+} bound by the SR. Note, however, that the preparation retained about 75% of its maximum fluorescence after treatment with Brij 58 and that about 20% of the fluorescence was background fluorescence already present before the application of CTC.

Using a Millipore filtration technique for monitoring changes in the CTC content of the medium bathing SR vesicles, Millman and Haynes[13] have recently demonstrated that CTC penetrates the SR. They concluded that both the influx and efflux of CTC are much slower than those of Ca^{2+}. These findings are consistent with the results obtained from skinned cardiac cells and summarised in Fig. 1 legend. Thus, the 10-min perfusion that preceded the tracing shown in Fig. 1*a* permitted the slow diffusion of CTC into the SR and its complexation with the Ca^{2+} bound to the SR membrane. As the [free Ca^{2+}] inside the SR attains a rapid equilibrium with the Ca^{2+} bound to the SR membrane, a decrease in the [free Ca^{2+}] inside the SR caused by Ca^{2+} release should decrease the amount of Ca^{2+} bound, and this should result in a decrease in fluorescence intensity[5–8]. Accordingly, the rapid fluorescence decreases observed in Fig. 1*a* are interpreted as a demonstration of Ca^{2+} release. Because of the slow efflux of CTC, most of the CTC that had penetrated the SR during the 10-min loading period remained trapped there after the Ca^{2+} release which caused the initial decrease of fluorescence (Fig. 1*a*). The subsequent application of solutions with increasing [free Ca^{2+}] caused a reloading of the SR with Ca^{2+} which resulted in a recovery of the fluorescence. Conversely, the sudden decrease in fluorescence observed when the [free Ca^{2+}] of the solution reached 1.8×10^{-7} M demonstrates a Ca^{2+}-induced release of Ca^{2+} from the SR.

The minimum [free Ca^{2+}] required for triggering a Ca^{2+}-induced fluorescence decrease varied between 5.6×10^{-8} M and 1.8×10^{-7} M in 22 experiments of the type shown in Fig. 1*a*. These values are within the same range as the [free Ca^{2+}] required for Ca^{2+}-induced release of Ca^{2+} from the SR previously inferred from tension recordings in skinned cardiac cells[9], and are lower than the [free Ca^{2+}] necessary to induce a detectable tension (about 1% of maximum) by the direct activation of the myofilaments, which was between 3.2×10^{-7} M and 5.6×10^{-7} M. Finally, the rate of the Ca^{2+}-induced decrease of fluorescence is in the same range as the rate of tension development in the intact rat ventricle at 22 °C.

All the experiments shown in Fig. 1 were carried out in the presence of 3.2×10^{-4} M free Mg^{2+} to permit comparison with our previous experiments on tension recordings that were done at this [free Mg^{2+}] (refs 1, 9). It has recently been suggested that the intracellular [free Mg^{2+}] of the intact muscle cell may be 10 times higher[14]. However, in eight experiments similar to that of Fig. 1*a*, but carried out in the presence of 3.2×10^{-3} M free Mg^{2+}, the [free Ca^{2+}] required to trigger a Ca^{2+}-induced decrease of fluorescence ranged between 1.0×10^{-7} M and 3.2×10^{-7} M. This was still less than the [free Ca^{2+}] required to induce a detectable tension by the direct activation of the myofilaments, which was 5.6×10^{-7}–1.0×10^{-6} M at this [free Mg^{2+}].

The preceding results (Fig. 1*a*) demonstrate directly a Ca^{2+}-induced release of Ca^{2+} from the mammalian cardiac SR. Fig. 1*b* and *c* correspond to additional findings which may help in understanding the mechanism of this process and in evaluating its relevance to the excitation–contraction coupling of the intact cardiac muscle. One of these findings is that the Ca^{2+}-induced release of Ca^{2+} depends not only on a critical level of [free Ca^{2+}] being reached in the myoplasm but also on the rate at which this change of myoplasmic [free Ca^{2+}] takes place. The initial part of Fig. 1*b* shows that increasing the [free Ca^{2+}] from 3.2×10^{-8} M to 1.8×10^{-7} M within 0.2 s caused a Ca^{2+}-induced decrease of fluorescence in this cell similar to that observed in the experiment shown in Fig. 1*a*. The cell was then subjected to the same succession of perfusions as in the experiment of Fig. 1*a* except that the second increase in [free Ca^{2+}] from 3.2×10^{-8} M to 1.8×10^{-7} M was effected very slowly, in 5.0 s. This resulted in no Ca^{2+} release but in a continued increase of fluorescence corresponding to further loading of the SR. With such a slow (5.0 s) perfusion change a minimum [free Ca^{2+}] in the range of 3.2×10^{-7}–5.6×10^{-7} M (17 experiments) was necessary to induce a Ca^{2+} release in the presence of 3.2×10^{-4} M free Mg^{2+}.

Although the mechanism of Ca^{2+}-induced release of Ca^{2+} is unknown, it was generally believed that the trigger was simply an increase of [free Ca^{2+}] outside the SR[1,2] or the gradient of [free Ca^{2+}] across the SR membrane[9]. The present results (Fig. 1*b*) indicate that this is not the case, although more experiments will be needed to define the exact relationship between the two variables—the level of [free Ca^{2+}] and the rate of change of [free Ca^{2+}]—on which the Ca^{2+} release depends. With respect to the physiological role of the Ca^{2+}-induced release of Ca^{2+} from the SR, the present findings (Fig. 1*b*) may help to explain some aspects of the force–frequency relationships of the intact heart. For example, it may be proposed that for each beat a rapid initial Ca^{2+} influx occurring during the plateau of the action potential may trigger the release of Ca^{2+} stored in the SR. This may be followed by a slower influx of Ca^{2+}, loading the SR with an amount of Ca^{2+} which will be available for release during subsequent beats.

Another finding is that the magnitude of Ca^{2+}-induced release of Ca^{2+} can be increased by at least two mechanisms: (1) an increase in the level of the [free Ca^{2+}] used as a trigger, and (2) an increase in the level of Ca^{2+} loading of the SR just before the triggering of the Ca^{2+} release. The initial part of the tracing of Fig. 1*c* shows that 3.2×10^{-7} M free Ca^{2+} induced a larger and much faster release of Ca^{2+} than was induced by 1.0×10^{-7} M free Ca^{2+}, even though the rate of perfusion change and, presumably, the level of Ca^{2+} loading were unchanged.

The end of the tracing of Fig. 1*c* shows that a slow increase in [free Ca^{2+}] from 3.2×10^{-8} M to 1.0×10^{-7} M did not induce a Ca^{2+} release (in contrast to the effect of a fast increase to the same level seen at the beginning of the tracing), but produced a continued increase in fluorescence. Note that the fluorescence remained below the level observed during the initial perfusion with 3.2×10^{-8} M free Ca^{2+} because the CTC content of the SR was the limiting factor and had decreased slowly during the experiment. However, the larger loading of the SR is unequivocally demonstrated (see discussion in Fig. 1 legend) by the greater magnitude of the fluorescence decrease induced by the rapid increase in [free Ca^{2+}] to 3.2×10^{-7} M after its slow increase to 1.0×10^{-7} M.

This gradation of the Ca^{2+} release demonstrated in Fig. 1*c* is relevant to the understanding of the mechanism of the Ca^{2+}-induced process, which must be more complex than the all-or-none process originally proposed[15]. It is also relevant to the compatibility of this process with the known gradation of cardiac contraction with the extracellular [Ca^{2+}] and with the magnitude of the trans-sarcolemmal Ca^{2+} current[16].

We thank Dr A. H. Caswell for advice, and the NHLBI and the AHA for financial support.

Specific tricyclic antidepressant binding sites in rat brain

Rita Raisman, Michael Briley & Salomon Z. Langer

Synthélabo, LERS, Department of Biology, 58, Rue de la Glacière, 75013 Paris, France

The discovery of high-affinity binding sites for psychoactive drugs such as benzodiazepines[1,2], opiates[3] and neuroleptics[4] has opened up new approaches to the study of these drugs and their mechanisms of action. Although most tricyclic antidepressants inhibit neuronal uptake of noradrenaline and serotonin[5], their mechanism of action remains unclear. Changes in the sensitivity of the β-receptor after chronic tricyclic antidepressant treatment[6,7] suggest that they modulate noradrenergic neurotransmission. Tricyclic antidepressants also act directly on cholinergic[8], histaminergic[9], α-adrenergic[10] and serotonergic[11] receptors. It is not clear, however, which, if any, of these effects

are related to the primary antidepressant effect or whether they are simply responsible for some of the side effects. We have thus investigated the possibility that specific binding sites for tricyclic antidepressants exist in the central nervous system. So far, binding studies using ^{3}H-labelled tricyclic antidepressant drugs have only detected binding to histaminergic H_2 and cholinergic muscarinic receptors[12] and low-affinity binding[13]. We demonstrate here a population of specific high-affinity binding sites for ^{3}H-imipramine on brain membranes which may be responsible for the antidepressant effects of these drugs.

Cerebral cortex dissected from 180–250 g male Sprague–Dawley rats was homogenised in 50 volumes of buffer (50 mM Tris-HCl, *p*H 7.4, 120 mM NaCl, 5 mM KCl) and centrifuged at 30,000*g* for 10 min. The pellet was twice resuspended in the same buffer and recentrifuged. The final, washed pellet was resuspended in 33.3 volumes of buffer (final protein concentration ~3 mg ml^{-1}). The binding of ^{3}H-imipramine was measured at 0 °C after incubating 180 µl of membrane suspension with ^{3}H-imipramine (0.5–20 nM) (specific activity 29.8 Ci mmol^{-1}, NEN) in a total volume of 250 µl for 60 min. 100 µl was taken and rapidly diluted into 5 ml ice-cold buffer and immediately filtered through Whatman GF/F glassfibre filters. The filters were washed with 3 × 5 ml ice-cold buffer, dried and the radioactivity measured by liquid scintillation spectrometry. The specific binding of ^{3}H-imipramine was defined as the difference between the total binding and that remaining in the presence of 10 µM desipramine. At 5 nM ^{3}H-imipramine, specific binding was 60% of the total binding.

Specific high-affinity ^{3}H-imipramine binding was saturable (Fig. 1) whereas the nonspecific binding increased linearly with ^{3}H-imipramine concentration. A Scatchard analysis of the specific binding (Fig. 1*b*) gave a straight line, indicating a single population of non-interacting sites. The mean apparent dissociation affinity constant, K_d, was 4.0 ± 0.5 nM (mean ± s.e.m., $n = 13$) and the total number of binding sites, B_{max}, was 13.8 ± 1.3 pmol per g original wet tissue weight. Hill analysis (not shown) gave a Hill number of 1.04, indicating a lack of cooperativity. ^{3}H-imipramine binding reached equilibrium rapidly even at 0 °C (Fig. 2). The $t_{1/2}$ for association at 2.5 nM ^{3}H-imipramine was 5 min. Dissociation, induced by an excess (10 µM) of desipramine, was also rapid, complete displacement being achieved within 60 min ($t_{1/2}$, 5 min).

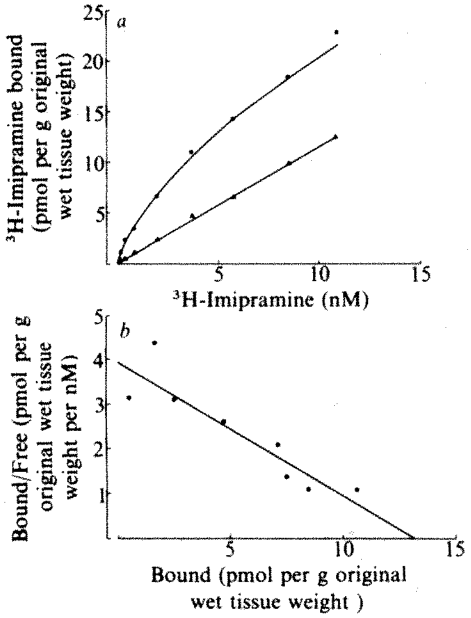

Fig. 1 Binding of ^{3}H-imipramine to rat cortical membranes. ^{3}H-imipramine at 0.1–12 nM was incubated in duplicate with or without excess desipramine (10 µM). *a*, Total binding (●) and that not displaced by 10 µM desipramine (▲) (nonspecific binding). *b*, The specific binding as a Scatchard plot ('bound', specifically bound ^{3}H-imipramine (pmol per g original wet tissue weight); 'free', free ^{3}H-imipramine (nM)).

Table 1 Inhibition of ^{3}H-imipramine binding in rat cortex

	IC_{50}(nM)		IC_{50}(nM)
Tricyclic antidepressants		Monoamine uptake blockers	
Imipramine	7	Fluoxetine	200
Desipramine	18	Nisoxetine	200
Protriptyline	20	Quipazine	700
Chloripramine	25	Cocaine	900
Amitriptyline	25		
Doxepin	300	Other drugs	
		Phentolamine	200
Atypical antidepressants		Chlorpromazine	200
		Pyrilamine	500
Iprindole	5,500	Serotonin	1,000
Viloxazine	11,500	WB 4101	2,000
Mianserin	20,000	Atropine	10,000
		Histamine	20,000

IC_{50} is the concentration required to inhibit 50% of the specific ^{3}H-imipramine binding at 5 nM. The following compounds were inactive (IC_{50} greater than 100 µM): pargyline, noradrenaline, dopamine, yohimbine, clonidine, methysergide, carbamylcholine, spiroperidol, cimetidine, Met-enkephalin, substance P, amphetamine.

The distribution of ^{3}H-imipramine binding sites varied among the major brain regions (cortex, striatum, cerebellum, hypothalamus). The greatest binding was found in the hypothalamus (K_d, 5.21 ± 3.4 nM; B_{max}, 15.97 ± 2.71 pmol per g original wet tissue weight, $n = 4$), which had seven to eight times more receptors than the region of lowest binding, the cerebellum (K_d, 8.0 ± 3.1 nM; B_{max}, 2.20 ± 0.39 pmol per g original wet tissue weight, $n = 3$). No ^{3}H-imipramine binding was detected in the heart.

All the tricyclic antidepressants studied are normally used clinically in the range of 60–300 mg per day. Five of these displaced ^{3}H-imipramine binding with very similar affinities (Table 1). Doxepin, however, was about 10-fold less potent. This difference may reflect a different absorption, distribution and metabolism for this drug *in vivo*. Tricyclic antidepressants, atypical antidepressants and monoamine uptake-blocking agents inhibited ^{3}H-imipramine binding (Table 1). However, the binding site for ^{3}H-imipramine seems to be distinct from the neuronal noradrenaline uptake site; cocaine, which blocks noradrenaline uptake, inhibits ^{3}H-imipramine binding fairly actively, but amphetamine, which *in vitro* is almost equipotent with cocaine in inhibiting noradrenaline uptake, is completely inactive at displacing the binding of ^{3}H-imipramine. Furthermore, ^{3}H-imipramime binding sites are absent in the rat heart whereas noradrenaline uptake is very active in this organ. Finally, a comparison of the inhibition of the uptake of dopamine, noradrenaline and serotonin by antidepressants with their potencies for the inhibition of ^{3}H-imipramine binding

Table 2 ^{3}H-Imipramine binding and monoamine uptake inhibition

	^{3}H-imipramine binding (IC_{50}, µM)	Uptake inhibition (IC_{50}, µM) DA	NA	5-HT
Imipramine	0.007	12.5	0.02	0.24
Desipramine	0.018	8.7	0.0015	2.24
Protriptyline	0.020	4.9	0.003	1.62
Chloripramine	0.025	3.8	0.044	0.015
Amitriptyline	0.025	5.6	0.020	—
Iprindole	5.5	7.9	2.6	10.0
Mianserin	20.0	19.0	0.084	11.0

The IC_{50} values for ^{3}H-imipramine binding are taken from Table 1. The uptake inhibition data are taken from Randrup and Braestrup[17]. DA, dopamine; NA, noradrenaline; 5-HT, Serotonin.

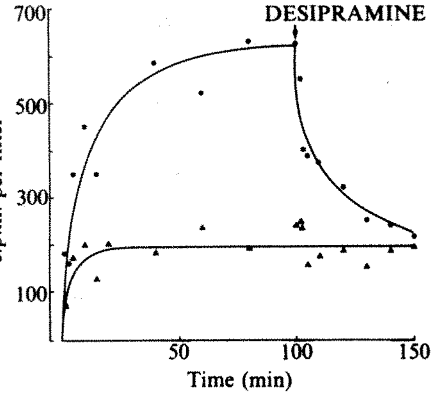

Fig. 2 Time course of ^{3}H-imipramine total (●) and nonspecific (▲) binding. 2.5 nM ^{3}H-imipramine was incubated with the membrane suspension at 0 °C as described in the text and samples were filtered at various times. At 100 min desipramine (10 μM) was added to displace the specifically bound ^{3}H-imipramine.

(Table 2) shows them to be unrelated. Desipramine, for example, which is at least 10 times more active than imipramine at inhibiting noradrenaline uptake and 10 times less active at inhibiting the uptake of serotonin, is almost equiactive with imipramine at inhibiting ^{3}H-imipramine binding. Although various other compounds were weakly active in inhibiting specific ^{3}H-imipramine binding (Table 1), there is no clear pattern or obvious relationship with other known pharmacological activities. Muscarinic and histaminergic H_2 receptors, which have been implicated in the action of tricyclic antidepressants,[8,9] do not seem to be involved, as atropine and cimetidine (muscarinic and H_2 histaminergic antagonists, respectively) are inactive.

It is difficult to establish a correlation between an *in vitro* biochemical activity of a drug and its clinical therapeutic efficacy in depression because of the heterogeneous nature of the clinical condition, the variable plasma levels resulting from the same dose and the similarity of potency for the commonly used antidepressants. Comparison of binding data with *in vivo* pharmacological tests which predict therapeutic drug activities is another possibility. The inhibition of reserpine-induced ptosis in mice is a widely used predictive test for antidepressant activity[14,15]. A comparison of the inhibition of reserpine-induced ptosis in mice with the inhibition of ^{3}H-imipramine binding in rats for a series of seven tricyclic and atypical antidepressants (imipramine, desipramine, amitriptyline, chloripramine, iprindole, viloxazine and mianserin) gave a correlation coefficient, *r*, of 0.588 ($P<0.25$) (R.R., M.B. and S.Z.L., unpublished results). A larger sample is, however, needed before any conclusions can be drawn. The poor correlation might be due to such factors as metabolic conversion to more or less active forms of the drugs and the possibility that tricyclic and atypical drugs really fall into two classes of which only the former act on the ^{3}H-imipramine binding site.

Thus, the specific binding of ^{3}H-imipramine to rat brain membranes is of high affinity, rapid, saturable and possesses a unique selectivity. It is, however, too early to say whether this binding is to an as yet undescribed receptor, as seems to be the case for the benzodiazepines. However, our results suggest that it may be related to the site of action of tricyclic antidepressant drugs, and as such could open up new approaches to the study of the biochemical basis of depression and its treatment with drugs.

A rapid communication of these findings has already been published[16].

Attempted asymmetric radiolysis of D,L-tryptophan with ^{32}P β radiation

W. A. Bonner & N. E. Blair

Department of Chemistry, Stanford University, Stanford, California

J. J. Flores

Ames Research Center, NASA, Moffet Field, California

In 1957 Vester[1] suggested that the then recently discovered[2,3] violation of parity in weak interactions might be ultimately responsible for the present unique chirality of asymmetric molecules in the biosphere. Since then there has been a growing number of investigations involving the longitudinally polarised electrons from natural β decay. Initial attempts[4,5] to detect asymmetric effects in several synthetic and degradative organic reactions using a number of β emitters failed and it was not until 1968 that Garay reported[6] that β radiation from ^{90}Sr/^{90}Y caused D-tyrosine to degrade more than L-tyrosine in alkaline aqueous solution. Studies have subsequently looked at the possible asymmetric interaction of β rays (or their bremsstrahlung) from a variety of sources (for example ^{104}Rh (ref. 7), ^{90}Sr/^{90}Y (refs 8, 9), ^{14}C (refs 10–12) ^{32}P (ref. 13) and polarised electrons from an accelerator[14,15]) with a number of racemic or optically active substrates (usually amino acids). Conflicting results emerging from these and certain related experiments have been tabulated[13]. Perhaps the most striking positive report among these studies is the claim by Darge and coworkers[13] that D,L-tryptophan (4.9×10^{-7} mol in 2 ml frozen (−25°C) aqueous solution) was 33% decomposed with a 19% relative enrichment of the D-enantiomer in the undestroyed residue by the action during 12 weeks of the β rays from 5 mCi of co-dissolved ^{32}P phosphate. The 33% gross decomposition was estimated from the UV absorption spectrum, and the 19% optical enrichment from the optical activity of the crude diluted reaction mixture, as compared with L-tryptophan at the same concentration ($\sim10^{-5}$ M). The observed optical rotations used in the latter calculation were minute, −0.0036° for L-tryptophan and +0.0007° ± 0.0004° (average of 16 observations) for the crude diluted reaction mixture. Because the remarkably large asymmetric effect claimed was based solely on these small observed rotations, and as the results have already been used by others in additional calculations[16], we thought it desirable to attempt to duplicate the observations of Darge *et al.*[13]. We report here the use of a different analytical technique to estimate the enantiomeric composition of the undecomposed residual tryptophan, namely, gas chromatography (GC). The significant advantages of GC over optical rotation for determining the enantiomeric composition of small amounts of an optically active component admixed with impurities have already been described[17].

Two 2-ml aliquots of a solution of D,L-tryptophan (5.1 mg) in 1.8×10^{-3} M HCl (100 ml) were placed in culture tubes and each was treated with 5 mCi (200 µl) of aqueous $KH_2\,^{32}PO_4$ solution (NEN). A control for each sample was prepared by mixing 2 ml of the above tryptophan solution with 200 µl 0.042 M KH_2PO_4. The tubes were sealed and stored at −25 °C for 85 days, then thawed and opened. The irradiated samples were each divided into two equal portions and one portion was treated with 20 µl of a 1.3×10^{-2} M solution of D-tryptophan to allow estimation of the per cent degradation using GC and the enantiomeric marker technique[18]. Each solution was then warmed and evaporated in a nitrogen stream and the residues were treated with 1 ml 2-propanol saturated with HCl gas. The culture tubes were sealed and heated at 120 °C for 2.5 h, opened and the volatiles were again evaporated in a nitrogen stream. The residues were treated with 1 ml ethyl acetate and 50 µl heptafluorobutyric anhydride, then were maintained at 120°C for 45 min. The volatiles were again evaporated and each oily residue was dissolved in dichloromethane to give an $\sim10^{-2}$ M solution for GC analysis. The samples were analysed as previously described[17] using a 46 m × 0.5 mm (i.d.) stainless steel capillary GC column coated with *N*-docosanoyl-D-valine-*tert*-butylamide phase[19]. At 160 °C (isothermal) and a N_2 flow rate of ~10 ml min^{-1}, baseline GC resolution of the enantiomeric tryptophan derivatives was achieved with the L-isomer eluting in 51.7 min and the D-isomer in 56.9 min. All samples were analysed in replicate, with the control samples interspersed 'back-to-back' with the irradiated samples. The results of these analyses are shown in Table 1, along with the analysis of a known mixture of D- and L-tryptophan which was included to see if an enantiomeric excess (e.e.) as small as ~6% could be reliably detected with such tryptophan derivatives by the GC technique used. A combined GC–mass spectra analysis of the above D,L-tryptophan derivative showed that each GC peak gave the same fragmentation pattern and corresponded to a tryptophan isopropyl ester having one heptafluorobutyryl residue on each nitrogen atom.

Table 1

‡ Containing 47.1% D- and 52.9% L-tryptophan.
s.d. Standard deviation.

Although the gross degradation which we observed (43.5% average, Table 1) was somewhat larger than that reported (33%) by Darge *et al.*[13], we found no evidence whatsoever for any asymmetric radiolysis. While the GC analyses in Table 1 do not seem to be quite as precise as those previously noted[17] for leucine enantiomers, it is nevertheless clear that the irradiated tryptophan residues have an enantiomeric composition not experimentally distinguishable from that of the D,L-tryptophan controls. Furthermore, the detection of a known 5.8% e.e. (as 3.4%) in the known mixture of Table 1 suggests that the ~19% e.e. (59.7% D-, 40.3% L-tryptophan) claimed by Darge *et al.*[13] could scarcely have been missed by the present GC technique. Unable to find an asymmetric effect after using an alternative analytical procedure (GC), we can only conclude that Darge's reported 19% asymmetric radiolysis of D,L-tryptophan with ^{32}P β radiation may have resulted from a systematic error in the very small polarimetric readings involved or from an artefact present in the crude solutions examined.

W. Darge*, I. Laczko† and W. Thiemann‡ reply: Bonner *et al.* criticise the reproducibility of our earlier results[1] and claim to have reproduced the original experiment. In fact they have applied a very different analytical technique based on gas-chromatographic analysis of the irradiation residue. There is also the difference that Bonner *et al.* have been able to analyse exclusively the enantiomeric composition of the partially destructed residual tryptophan only, while in our earlier optical rotatory dispersion (ORD) measurements we were able tc detect the effect of the sum of all potential chiral products (be they residual tryptophan, intermediate or final irradiation products such as any oxyacids, ketonic, or even peptidic substances commonly encountered in similar experiments). There are possibilities that any such intermediate products exhibit quite specifically large optical rotations and thus contribute to the overall effect in spite of their possibly small concentration in the investigated solution. We believe that this is exactly the advantage of a carefully performed ORD measurement over GC or other analytical methods. Having eliminated 'physical artefacts' as far as possible according to available techiques[2], one is left with any 'chemical artefacts' in the above defined sense, namely the existence of hitherto unidentified chiral intermediate irradiation products in the chain of the decomposition process of D,L-tryptophan. We never had claimed that any 'stereoselective effect' would manifest itself necessarily in the destruction of racemics but included the equally probable chance of stereoselective synthesis as a source of optical activity.

We wonder why Bonner *et al.* declare out earlier results as 'the most striking positive result': Garay in his original paper[3] and Merwitz[4] had both published much larger 'striking' stereoselective effects as a result of irradiation. Bonner *et al.* themselves confirm the basic hypothesis with their polarised electron bombardment of D,L-leucine[5]. What then is the essential difference between accelerated polarised electrons and β^- particles emitted from radionuclides in this context of 'helicity transferred from the classically physical level to the chemical level'?

Evidence that three structural genes code for human alkaline phosphatases

Lorne E. Seargeant & Robert A. Stinson

Department of Pathology, Medical Laboratory Science, University of Alberta, Edmonton, Alberta, Canada T6G 2G3

The number of structural gene loci that code for the different molecular forms of human alkaline phosphatase is unknown. Physical properties of the enzymes, immunological data, chemical inhibition and genetic studies suggest that at least three structural genes[1] are involved: one coding for alkaline phosphatase from placenta, another for the enzyme from intestine, and one or more for the enzymes from liver, kidney and bone. Badger and Sussman[2] have shown that alkaline phosphatases from human liver and placenta are products of different structural genes, and Greene and Sussman[3] have shown that alkaline phosphatase from a metastasised bronchogenic carcinoma was nearly identical to the enzyme from placenta. However, other tumour-associated alkaline phosphatases and the enzymes from normal tissues other than placenta and liver have not been identified by conclusive structural criteria[4], and thus it is not known whether these onco-alkaline phosphatases represent ectopic production or unusual post-translational modification of the enzymes found in normal tissues. We present here, using a sensitive peptide-mapping technique[5], structural evidence that the enzyme forms from liver, kidney and serum from a patient with Paget's disease of bone (osteitis deformans) are products of the same structural gene and can be easily distinguished from either the intestinal or placental isoenzymes. The technique seems to be useful for the classification of tumour-associated alkaline phosphatases on a structural basis.

The relative pattern of radiolabelled peptides (Fig. 1) clearly shows that there are remarkable structural similarities between the enzymes purified from liver, kidney or Paget's serum. The maps of the radiolabelled peptides of alkaline phosphatase from intestine or placenta are markedly different from each other and from those for the other tissues. Products of different structural genes would be expected to show significant differences in amino acid sequences[11] and therefore have different tryptic–peptide compositions. But, allelic proteins of a single structural gene generally have almost identical amino acid sequences[11] and therefore would be more difficult to identify on the basis of tryptic–peptide composition. Thus our evidence strongly suggests that only three structural gene loci code for these alkaline phosphatases. The enzymes from intestine or placenta are products of two different loci, and the enzymes found in kidney, liver and in a serum from a patient with Paget's disease of bone, are products of a third locus.

The origin of the elevated serum alkaline phosphatase found in patients with Paget's disease of bone has not been proved, although it is generally considered to be derived from increased osteoblast activity[12]. The alkaline phosphatase level as determined by catalytic activity in the Paget's serum used in these studies was 30–40 times the level found in normal sera. The major component of the serum alkaline phosphatase was obtained in homogeneous form in 26% yield and was characterised as 'bone-type' alkaline phosphatase by heat stability, electrophoresis and differential inhibition studies.

Evidence that the stained protein bands were alkaline phosphatase protein was derived from experiments in which heating at 100 °C for 5 min was omitted when samples were prepared for SDS polyacrylamide gel electrophoresis (PAGE). The unheated samples in 1% SDS showed a single enzymatically active, slow-moving band which was coincident with the single protein-stained band[6]. When the protein is heated in 1% SDS in preparation for SDS-PAGE the enzymatically active band disappears and a faster migrating inactive band appears (equivalent to the subunit molecular weight) (Fig. 2). Peptide maps resulting from either treatment were identical. Also, the loss of enzymatic activity on prolonged incubation at 30 °C in the presence of 1% (w/v) SDS and 5% (v/v) mercaptoethanol was correlated with the disappearance of the slow-moving active band and the appearance of the faster inactive band in the SDS gels[6]. In addition, the peptide map of the protein band from analytical PAGE[13] of a liver alkaline phosphatase preparation was identical to that obtained by SDS-PAGE. We have also carried out chemical inhibition, electrophoretic, isoelectric focusing and heat stability studies on both the native and desialylated enzymes from each source (unpublished results). We found that these results are entirely consistent with the three structural gene loci hypothesis that is strongly supported by the peptide maps. Furthermore, the properties of the individual enzymes were as would be expected from the appropriate tissue source.

Note that, although the apparent subunit molecular weight (MW) values determined by SDS-PAGE may not be accurate, as the enzymes are glycoproteins and could migrate anomalously on polyacrylamide gels[14], the enzymes from liver, kidney, intestine and Paget's serum all had apparent subunit MWs of ~92,000. The enzyme from kidney was heterogeneous and had subunit MWs of ~96,000, 70,000 and 53,000. However the peptide maps from these three bands suggest that the two lower MW species may have been derived from the larger protein species and thus may represent partially degraded enzyme protein. This degradation may have occurred during the isolation procedure.

The relative spot intensity of two peptide maps from the same preparation is variable. This may be due, at least in part, to variation in the extent of radiolabelling with ^{125}I. It is likely that tyrosine residues are selectively iodinated, but diiodotyrosine derivatives as well as iodinated derivatives of phenylalanine and histidine may also be formed[15]. Thus peptides may be represented by more than one spot depending on the extent of iodination.

Alkaline phosphatase from various sources may differ in carbohydrate composition. However, the similarity of the peptide maps of alkaline phosphatase from liver, kidney and Paget's serum suggests that differences in carbohydrate composition, if present, have little influence on the resultant peptide map. Elder *et al.*[16] have suggested that the glycopeptides do not migrate in the apolar solvent system used here for thin-layer chromatography. Also our observation that the peptide maps for native and desialylated liver alkaline phosphatase were very similar suggests that the presence of carbohydrate does not greatly influence the results.

The approach used here to classify tissue alkaline phosphatases on a structural basis is suitable for the identification of the enzyme from normal and cancerous tissues. Maps of the radioiodinated peptides can readily be obtained in only a few days using less than 2 μg alkaline phosphatase protein. In addition, it is not necessary to purify the protein to homogeneity provided that it can be separated sufficiently from other proteins by SDS-PAGE (or other techniques) to allow excision of the stained protein band from the gel. Classification of alkaline phosphatases by structural composition will avoid the potential inaccuracies present when classifying gene products on the basis of heat stability, differential inhibition, immunological specificity, electrophoretic mobility or other functional properties.

Another technique used by others to study the structure of alkaline phosphatases is active site labelling with ^{32}P. Two-dimensional electrophoretic analysis of the labelled enzyme or one-dimensional electrophoresis of the labelled and partially trypsin degraded enzyme have been used to compare the enzymes from milk, placenta, liver, bone and intestine[17,18]. Active site peptides of alkaline phosphatase have been similarly studied[19]. However, this technique is usually applied to impure preparations and makes the assumption that alkaline phosphatase is the only protein that incorporates phosphate in the

0028-0836/79/370152—03$01.00

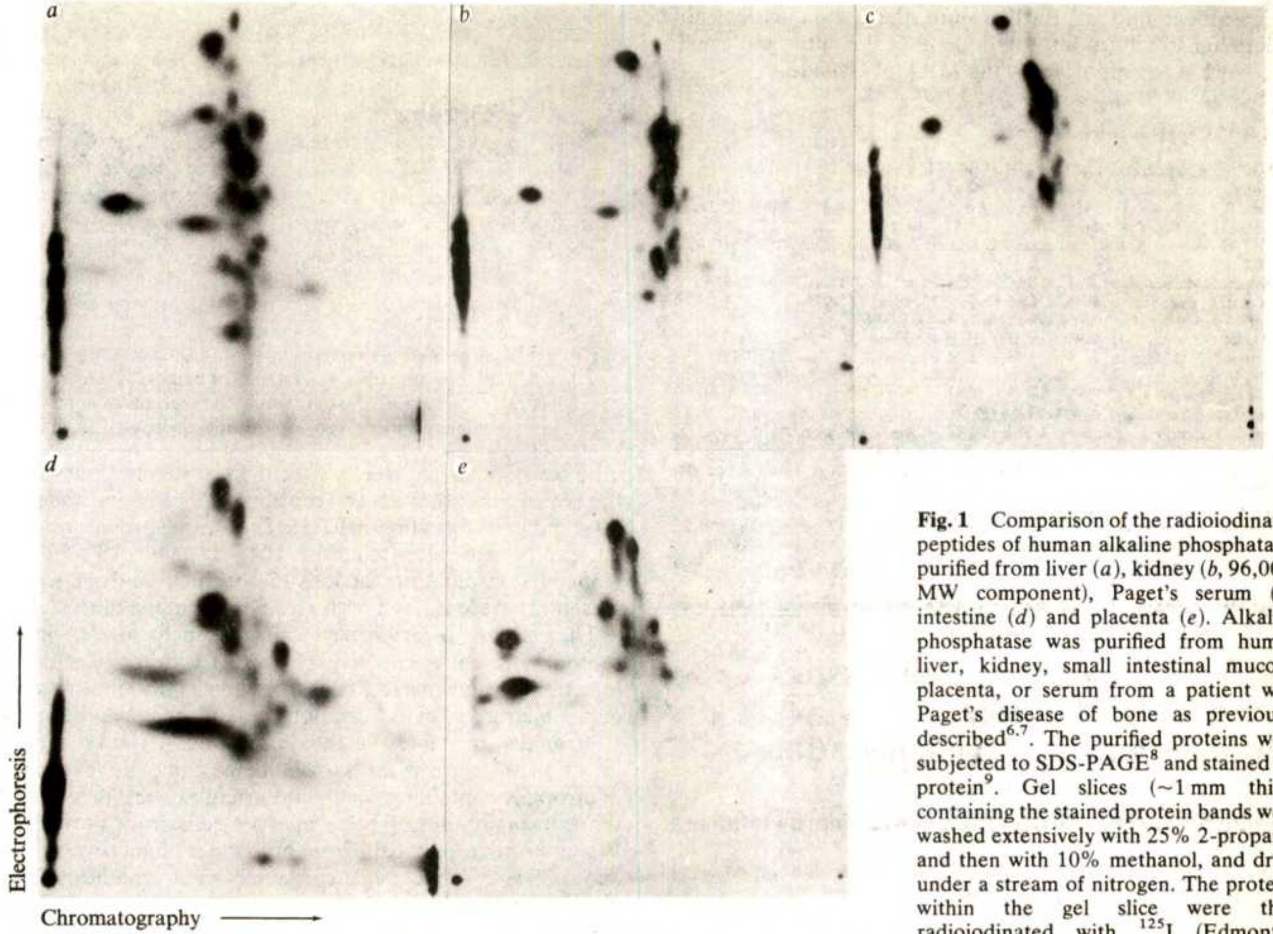

Fig. 1 Comparison of the radioiodinated peptides of human alkaline phosphatases purified from liver (*a*), kidney (*b*, 96,000-MW component), Paget's serum (*c*), intestine (*d*) and placenta (*e*). Alkaline phosphatase was purified from human liver, kidney, small intestinal mucosa, placenta, or serum from a patient with Paget's disease of bone as previously described[6,7]. The purified proteins were subjected to SDS-PAGE[8] and stained for protein[9]. Gel slices (~1 mm thick) containing the stained protein bands were washed extensively with 25% 2-propanol and then with 10% methanol, and dried under a stream of nitrogen. The proteins within the gel slice were then radioiodinated with ^{125}I (Edmonton Pharmaceutical, specific activity ~17 Ci mg^{-1}) by a modification of the chloramine *T* method[10] as described by Elder *et al.*[5]. Each gel slice was dried under a stream of nitrogen and incubated in 0.5 ml of 50 μg ml^{-1} trypsin (Sigma T-1005, 7,500 U mg^{-1}) in 50 mM NH_4HCO_3 buffer (*p*H 8.0) for 16 h at 37 °C, after which the supernatant was lyophilised. The tryptic digests were then analysed by thin-layer electrophoresis followed by thin-layer chromatography in a second direction. The lyophilised samples were dissolved in 20 μl of solution A (acetic acid/formic acid/water, 15:5:80) and ~1×10^6 c.p.m. (1–5 μl) were spotted onto 20 cm × 20 cm cellulose-coated TLC plates (Eastman Kodak). The plates were moistened with solution A and electrophoresed at 1,000 V for ~1 h at 8 °C. The plates were dried and chromatographed in a second direction using a solvent mixture containing butanol/pyridine/acetic acid: water (65:50:10:40). Radioactivity was detected by autoradiography using Kodak XR-1 X-ray film with an intensifying screen (Dupont, Cronex par speed) and exposure at −70 °C for 4 h, or as required.

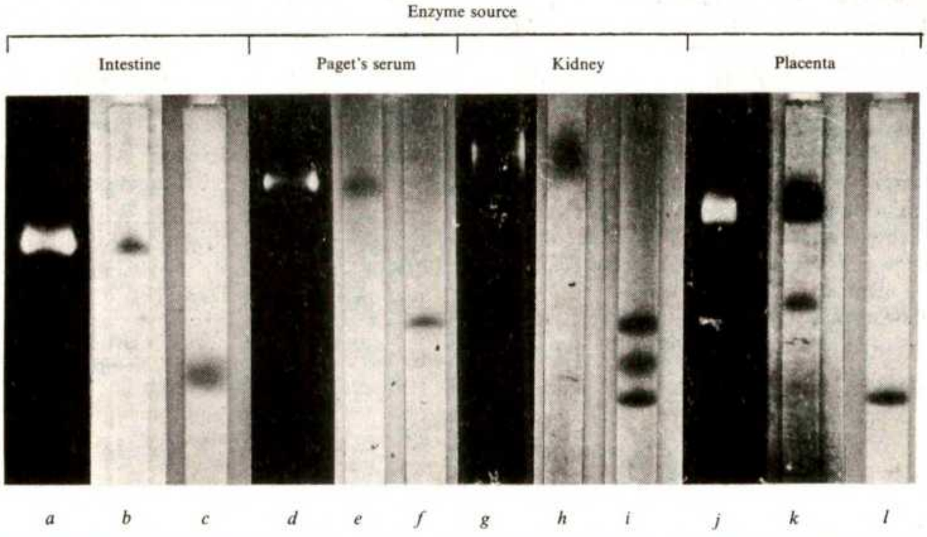

Fig. 2 Purity of alkaline phosphatases from human tissues. Alkaline phosphatases purified from small-intestinal mucosa, Paget's serum, kidney or placenta were subjected to SDS-PAGE[8] in denaturating and non-denaturing conditions. Identical criteria of purity for the enzyme from liver have been previously presented[6]. Non-denaturing conditions were identical to denaturing conditions except that heating the sample in 1% SDS to 100 °C for 5 min was omitted; instead, the sample in 1% SDS was left at room temperature for 5 min. *a, d, g, j*, Samples were prepared in non-denaturing conditions, electrophoresed, stained for enzyme activity[6], photographed and then (*b, e, h, k*) stained for protein[9]. *c, f, i, l*, Samples were prepared in denaturing conditions, electrophoresed and stained for protein[9]. Samples not denatured showed an enzymatically active band which corresponded to a protein-stained band. Two protein-stained bands were evident for nondenatured placental enzyme and both of these were active. In denaturing conditions samples from intestine, Paget's serum or placenta showed a single protein-stained band and the enzyme from kidney showed three bands (see text). For any one tissue denatured and non-denatured protein gave identical peptide maps. The two faster migrating bands in the kidney sample appeared to be proteolytic degradation products.

experimental conditions. Furthermore, the technique does not give detailed structural information about the entire molecule.

Clonal nature of mast-cell clusters formed in W/W^v mice after bone marrow transplantation

Yukihiko Kitamura, Hiroshi Matsuda & Kaoru Hatanaka

Institute for Cancer Research and Department of Pathology, Medical School, Osaka University, Kita-ku, Osaka, 530 Japan

We have recently found that the number of mast cells in the skin of adult W/W^v mice is less than 1% of that observed in congeneic +/+ mice, and that no mast cells are detected in other tissues of W/W^v mice[1]. After the transplantation of bone marrow cells from congeneic +/+ mice, the number of mast cells in the skin, stomach, caecum and mesentery of the W/W^v mice increased to levels similar to those of the +/+ mice[1]. Study of the mast-cell number in the W/W^v mice at various times after transplantation suggested to us that mast cells might develop in groups, particularly in the skin and mesentery. In this report, we have attempted to elucidate the possible clonal origin of such mast-cell clusters from a single precursor cell, using giant granules of beige (C57BL/6-bg^J/bg^J, Chediak–Higashi syndrome) mice as a marker to identify the origin of the mast cells[2–4] (Fig. 1). We found that when WB-W/+ × C57BL/6-W^v (WBB6F$_1$)-W/W^v mice were injected with a mixture of bone marrow cells from beige C57BL/6 mice and normal C57BL/6 mice, more than 95% of mast-cell clusters consisted of either beige-type cells alone or normal-type cells alone. We conclude, therefore, that the cluster of mast cells originated from a single precursor cell.

Three-month-old WBB6F$_1$-W/W^v mice were injected with bone marrow cells from either beige C57BL/6 mice (2×10^7) or normal C57BL/6 (2×10^7), or with a mixture of bone marrow cells from beige C57BL/6 mice (10^7) and normal C57BL/6 mice (10^7).

On various days after the cell injection, a blood sample was obtained from a lateral tail vein of W/W^v recipient mice, and the number of erythrocytes was counted with a haemocytometer. The smears were fixed in formaldehyde vapour, stained with Sudan Black B and counterstained with Giemsa solution[5,6]. One hundred neutrophils with distinctly segmented nuclei were scored for the presence or absence of giant sudanophilic granules.

A biopsy of the dorsal skin of the W/W^v recipient mice was carried out 10 weeks after bone marrow transplantation, and the mice were killed 15 weeks after the transplantation. Pieces of the dorsal skin, stomach and caecum were removed and fixed in 10% buffered formalin (*p*H 7.2). The stretch preparation of the mesentery was also fixed in 10% formalin. Tissues were embedded in paraffin; sections (5 μm thick) and the stretched mesentery were stained with acidified toluidine blue.

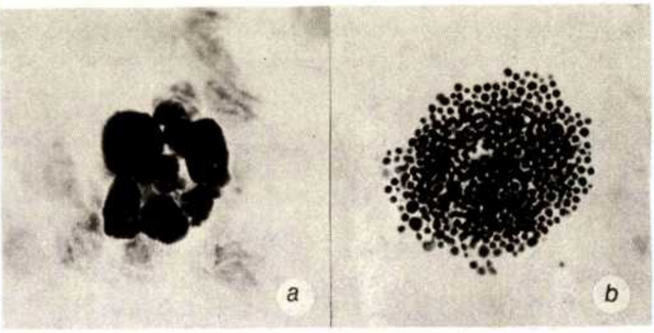

Fig. 1 Mast cells in a stretch preparation of mesentery, stained with acidified toluidine blue. *a*, Mast cell of beige C57BL/6 mouse; *b*, Mast cell of normal C57BL/6 mouse. The granules in the beige cell are significantly increased in size and decreased in number.

The number of erythrocytes increased to levels similar to those of normal mice (WBB6F$_1$-+/+) within 6 weeks of the injection of bone marrow cells from beige mice or normal mice, or the mixture of cells from both types of mice. About 80% of neutrophils contained giant granules 15 weeks after the injection of marrow cells from beige mice. In contrast, no neutrophils containing such giant granules were detected after the transplantation of bone marrow cells from normal mice. When the mixture of cells from both types of mice was injected, about 30% of neutrophils contained giant granules 15 weeks after transplantation.

Clusters of mast cells were detected in the sections of the skin removed by biopsy 10 weeks after the cell injection (Fig. 2*a*). All clusters consisted of mast cells containing giant granules alone when bone marrow cells of beige mice had been injected, whereas they were all composed of mast cells containing granules of regular size when the cells of normal mice had been used. When the mixture of cells from both types of mice was transplanted, about half of the clusters contained beige-type mast cells alone and the other half contained only normal-type mast cells. Although very few clusters were observed to contain both types of cells, one type of cell was predominant (more than 90% of total) in all cases. Serial sections of the skin revealed that the type of mast cells did not change in different parts of the same cluster.

In the skin, stomach and caecum of WBB6F$_1$-W/W^v mice killed 15 weeks after the injection of mixed marrow cells, it was

Total	101	88	7	196

The method of bone marrow transplantation has been described previously[1].

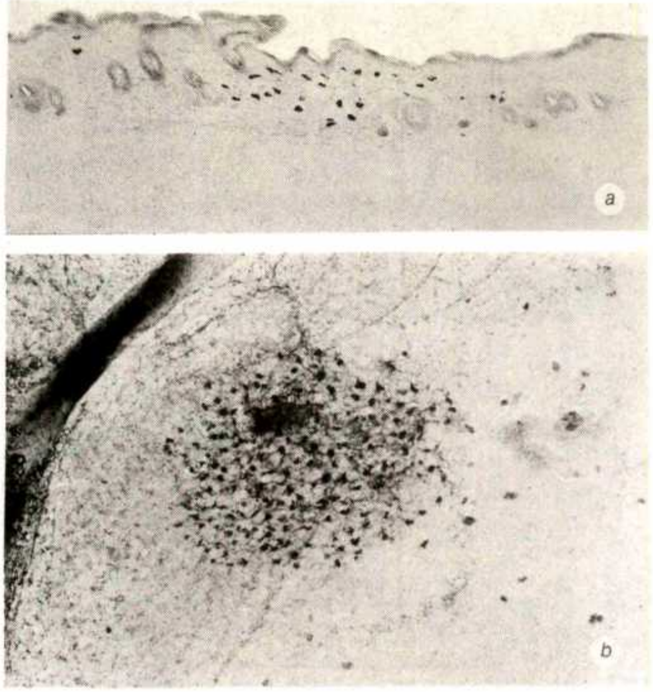

Fig. 2 *a*, A mast-cell cluster in the skin of a WBB6F$_1$-W/W^v mouse detected 10 weeks after bone marrow transplantation. A group of more than 10 mast cells in one section (5 μm thick) was defined as a cluster. *b*, A mast-cell cluster in the mesentery of a WBB6F$_1$-W/W^v mouse detected 15 weeks after the bone marrow transplantation. A discrete group of more than 20 mast cells in the stretched mesentery was defined as a cluster.

rather difficult to find discrete clusters because of the diffuse development of the mast cells. However, only one type of mast cell seemed to predominate in any given area of tissue.

In contrast with other tissues, discrete clusters of mast cells were observed in the stretched mesentery 15 weeks after bone marrow transplantation (Fig. 2*b*), located mainly in the fat tissue near blood vessels. As all cells contained in a cluster could be scored in the stretched mesentery without tedious examination of serial sections, the type and number of mast cells in each cluster were determined. As shown in Table 1, 189 out of 196 clusters (96%) consisted of either beige-type mast cells or normal-type mast cells. The largest cluster contained about 300 cells.

The present results demonstrate that mast-cell clusters which appeared in the skin and mesentery of W/W^v mice after the transplantation of bone marrow cells are derived from a single precursor cell. This is consistent with our recent observation that the precursor of the mast cell migrates through the bloodstream[7] and proliferates at the site of differentiation[4]. The bone marrow-derived precursor cell seems to produce up to 300 progenies when it differentiates into mast cells in the mesentery.

We have recently found that mast cells are as severely decreased in number in the Sl/Sl^d mice as in W/W^v mice[8]. In contrast to W/W^v mice, the number of mast cells in Sl/Sl^d mice did not increase after the transplantation of bone marrow cells from congeneic +/+ mice[8]. The injection of bone marrow cells from Sl/Sl^d mice increased the number of mast cells in the skin, stomach, caecum and mesentery of W/W^v mice. This indicates the presence of mast-cell precursors in the bone marrow of Sl/Sl^d mice[8]. The failure of haematopoietic colony formation in the spleen of Sl/Sl^d mice[9] and the failure of melanocyte differentiation in the skin of the same mutant mice[10] are attributed to a defect in the microenvironment[10–12]. The development of mast-cell clusters also seems to be under the control of the microenvironment.

We thank Dr K. J. Mori for reviewing the manuscript, and Professor K. Matsumoto and Dr K. Ezumi for valuable discussions. The mice were obtained from the Jackson Laboratory. This work was supported in part by the Japanese Ministry of Education, Science and Culture.

Interaction of C-reactive protein with artificial phosphatidylcholine bilayers

John E. Volanakis

Division of Clinical Immunology and Rheumatology, University of Alabama in Birmingham, Birmingham, Alabama 35294

Karel W. A. Wirtz

Laboratory of Biochemistry, University of Utrecht, Utrecht, The Netherlands

C-Reactive protein (CRP), the most characteristic of the 'acute phase proteins' (ref. 1) is thought to participate in the mediation and/or modulation of acute inflammatory processes, but its exact function is unknown. CRP has a Ca^{2+}-dependent binding specificity for phosphorylcholine,[2] the polar head group of two widely distributed lipids, lecithin (phosphatidylcholine, PC) and sphingomyelin (SM). A number of observations [3–5] suggest that at least some of the biological activities of CRP depend on its interaction with phospholipids of cell membranes. In addition, interaction of CRP with PC- and SM-containing lipid dispersions[6] and with PC-containing liposomes[7] can activate the complement system. We report here that binding of CRP to model membranes of PC requires the incorporation into the bilayer of lysophosphatidylcholine (LPC). Thus, a disturbance of the molecular organisation of the bilayer appears to be necessary for binding of CRP. These findings provide a possible biochemical explanation for binding of CRP to damaged but not intact cell membranes[3] and might be relevant to its biological function.

Binding of CRP to multilamellar PC-liposomes and single-walled PC-vesicles was studied by molecular sieve chromatography on agarose columns. CRP was purified from ascitic fluid by a recently described method[8] and labelled with ^{125}I by the lactoperoxidase method[9]. PC from egg yolk, LPC and phosphatidic acid (PA) were prepared as described previously [10]. Their purity was ascertained by thin layer chromatography on silica gel H. In initial experiments the binding of CRP to multilamellar liposomes and single-walled vesicles was examined. To this end, lipid dispersions consisting of PC, cholesterol and PA (77:15:8 mol%) were sonicated for short periods and after incubation with ^{125}I-CRP were subjected to chromatography on Sepharose-4B columns. As shown in Fig. 1, two peaks of phosopholipid were obtained: one containing large multi-layered liposomes corresponding to the void volume of the column, and a second containing small single-walled vesicles[11]. ^{125}I-CRP eluted from the column as a separate single peak at the same position as unbound protein. In addition, binding of ^{125}I-CRP was tested with neutral, negatively charged (10 mol% PA) and positively charged (10 mol% stearylamine) PC-vesicles by subjecting the CRP-vesicle mixture to chromatography on Bio-Gel A-0.5m columns. In repeated runs, the phospholipid and the protein eluted from the column as distinctly separate peaks. Only a small amount of the eluted

^{125}I-CRP (1–13%) was occasionally found associated with the vesicle peak. Identical results were obtained with dimyristoyl-PC and also when up to 40% cholesterol was incorporated into negatively charged vesicles. Similarly, when unlabelled CRP was substituted for ^{125}I-CRP only 10% of the eluted protein was associated with the vesicle peak. In these experiments, the concentration of CRP in the eluted fractions was determined by measuring intrinsic tryptophan fluorescence.

On the basis of these data we conclude that CRP cannot form a complex with the polar head group of PC present in an artificial bilayer. Given the known binding affinity of CRP for phosphorylcholine[12], these data could be interpreted to indicate that in intact PC bilayers the polar head groups are not freely accessible to the protein. This interpretation seems to contradict available models of the structure of phospholipid bilayers which indicate that polar head groups are exposed to the external aqueous phase and thus available for reaction. However, NMR data on artificial PC-bilayers have demonstrated the presence of intramolecular interactions between polar head groups restricting the extent of their accessibility to the water phase[13]. Furthermore, studies using human red cells revealed that hydrolysis of phosphoglycerides by phospholipase C required the presence of surfactants [14], indicating that the polar head groups were not freely accessible to this enzyme in the intact bilayer. These considerations led us to test the effect of detergent incorporation into the PC-bilayers on the binding of CRP. Considerable amounts of detergent can be incorporated into PC bilayers without disrupting them[15], and up to 50 mol% of LPC, Triton X-100 or SDS does not cause a breakdown of the bilayer structure. On the other hand, incorporation of detergent results in changes in a number of the known properties of the bilayers including changes in permeability[16], transition temperature[17] and susceptibility to hydrolysis by lipolytic enzymes[14].

The effect of incorporating increasing amounts of LPC into PC-vesicles on the binding of ^{125}I-CRP is shown in Fig. 2. At a molar ratio of PC:LPC 2:1, 83% of the eluted ^{125}I-CRP was found associated with the phospholipid peak. The ratio of radioactivity to lipid phosphorus was constant across the peak, indicating homogeneous binding of the protein to the vesicles. This shows that the membrane interface formed by PC and LPC exposes the phosphorylcholine group to the extent that CRP can form a regular complex. Increasing the molar ratio of PC:LPC resulted in a decrease of the percentage of vesicle-bound ^{125}I-CRP with a concomitant increase of the free ^{125}I-CRP peak. Thus, the percentage of eluted ^{125}I-CRP found associated with vesicles containing PC:LPC at molar ratios of 4:1, 10:1 and 1:0 (no LPC) was 73, 34 and 12%, respectively.

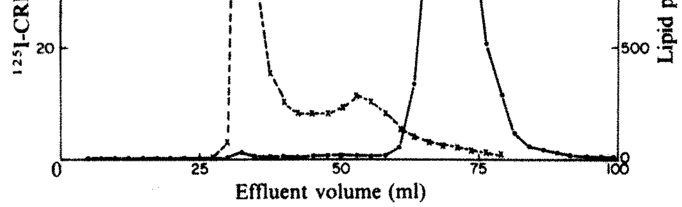

Fig. 1 Gel filtration of a mixture of ^{125}I-CRP and PC-vesicles using Sepharose 4B. Vesicles were prepared by suspending 55 μmol egg-PC, 11 μmol cholesterol and 5.5 μmol PA in 5.0 ml of 10 mM Tris-HCl, 150 mM NaCl, 2 mM $CaCl_2$, pH 7.2. The dispersion was subjected to sonic irradiation for 10 min at 0 °C under a stream of nitrogen, using a Branson tip sonifier at 70 W. Vesicles (6.6 μmol PC) were incubated with 0.56 nmol ^{125}I-CRP in a total volume of 0.8 ml for 30 min at room temperature. The mixture was then applied on a 1.5 × 45 cm column of Sepharose 4B equilibrated in 10 mM Tris, 150 mM NaCl, 2 mM $CaCl_2$, pH 7.2. Phospholipid content of fractions is expressed as lipid phosphorus, measured by the method of Rouser *et al.*[19]. The recovery of applied protein and lipid was 78% and 75% respectively.

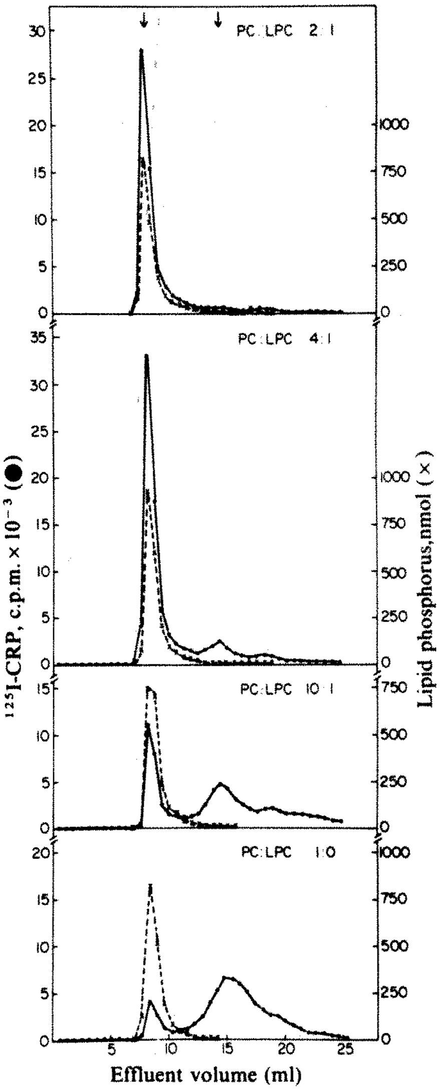

Fig. 2 Gel filtration of mixtures of ^{125}I-CRP and PC-vesicles containing various amounts of LPC, using Bio-Gel A-0.5 m. Vesicles were prepared from a chloroform solution of a mixture of egg-PC and egg-LPC at the indicated molar ratios. The lipid was dried by rotary evaporation under reduced pressure and dispersed in 10 mM Tris-HCl, 150 mM NaCl, pH 7.2 at a concentration of 12 μmol ml^{-1}. The dispersion was sonicated under nitrogen at 0 °C until it became clear. Sonication time varied from 10 min for the PC:LPC 2:1 vesicles to 45 min for the PC vesicles. The vesicle preparations were then centrifuged at 160,000g for 30 min to remove metal particles and large lipid aggregates. Vesicles (2.6 μmol of phospholipid) were incubated for 30 min at room temperature with 0.23 nmol ^{125}I-CRP in a total volume of 315 μl in buffer containing 9.5 mM $CaCl_2$. The mixture was then applied on a 7 × 45 cm Bio-Gel A-0.5 m column equilibrated and eluted with 10 mM Tris-HCl, 150 mM NaCl, 2.5 mM $CaCl_2$, pH 7.2. Mean recoveries ± s.e.m. for ^{125}I-CRP and phospholipid were 67 ± 4% and 79 ± 3%, respectively. The arrows indicate elution volumes of blue dextran (left) and ^{125}I-CRP (right).

To examine whether the observed binding of CRP to the vesicles was an exclusive function of LPC or could also be reproduced with other surfactants, three other surfactants were also examined. Figure 3 shows that Triton X-100 (Rohm and Hass), or sodium deoxycholate (DOC, Merck) incorporated into egg-PC-vesicles at molar concentrations of 45% did not promote the binding of ^{125}I-CRP to the vesicles. The experiment with Triton X-100 was repeated by equilibrating and eluting the column in buffer containing 0.35 mM Triton X-100, which is slightly above its critical micellar concentration, to avoid dissociation of the surfactant from the vesicles during the chromatography[18]. Again, no binding of ^{125}I-CRP to the vesicles was observed. However, when sodium dodecyl sulfate (SDS, Merck) was incorporated into PC-vesicles at the same molar concentration of 45%, some binding of ^{125}I-CRP was observed. As shown in Fig. 3, 38% of the eluted protein was associated with the SDS-containing vesicles. This compares to a binding of 84% for the PC-vesicles that contain LPC at a molar concentration of 50%.

The present data demonstrate that LPC is by far the most effective surfactant in promoting the binding of CRP to PC vesicles. We do not yet know whether binding occurs to the polar head group of LPC or to that of LPC and PC. The failure of Triton X-100 and DOC to promote binding raises the question of whether derangement of the molecular organisation of the PC bilayer is a prerequisite for binding. On the other hand, different surfactants are known to interact differently with phospholipid bilayers, the mode of interaction depending on such factors as the overall conformation, size, charge and length of acyl chain[15]. In terms of the possible biological implications of the present observation, previous data on the *in vivo* deposition of CRP are relevant. Kushner and Kaplan[3] reported that at experimental inflammatory sites CRP could be demonstrated in close association with membrane structures of altered or necrotic but not of normal cells. Thus, an alteration or complete breakdown of the natural orientation of cell membranes appeared to be necessary for *in vivo* binding of CRP, although the nature of the CRP-binding moieties was not determined. However, considering the two sets of data together, it seems reasonable to speculate that following tissue injury or necrosis, CRP can bind to phosphorylcholine-containing phospholipids of necrotic or altered cell membranes. As previously suggested[6], such binding could lead to complement activation and generation of chemotactic and opsonic factors, resulting in attraction of phagocytic cells and enhanced phagocytosis and thus contributing to the repair of the injured site. This hypothetical sequence of events should be considered as a possible biological function of CRP.

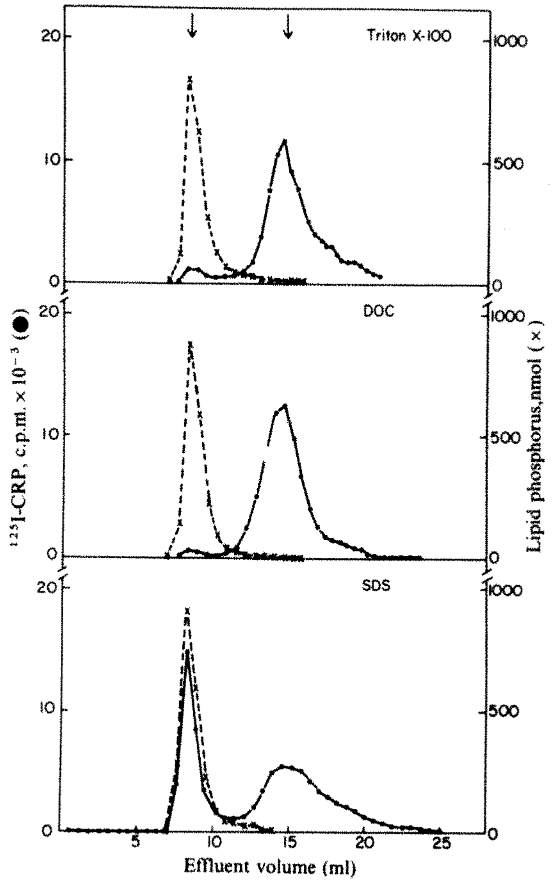

Fig. 3 Gel filtration of mixtures of ^{125}I-CRP and PC-vesicles containing various surfactants, using Bio-Gel A-0.5 m. Vesicles were prepared by dispersing egg-PC (11 μmol ml^{-1}) in 10 mM Tris-HCl, 150 mM NaCl, *p*H 7.2 containing 5 μmol ml^{-1} of the respective surfactant. Each dispersion was sonicated until it became clear (3–5 min). Other experimental details were as for Fig. 2. Mean recoveries ± s.e.m. for ^{125}I-CRP and phospholipid were 82 ± 4% and 88 ± 1%, respectively.

Evidence for the bilobal nature of diferric rabbit plasma transferrin

B. Gorinsky, C. Horsburgh, P. F. Lindley, D. S. Moss, M. Parkar & J. L. Watson

Department of Crystallography, Birkbeck College, University of London, Malet Street, London WC1, UK

Plasma transferrin is involved in iron transport within the circulatory system of vertebrates, and provides an iron source for haemoglobin synthesis and other metabolic requirements. However, despite extensive studies by spectroscopic, biochemical and physiological techniques, the nature of iron binding and the mechanisms of uptake and release of iron are not fully understood. Plasma transferrins[1] are monomeric glycoproteins with a molecular weight of approximately 80,000 (ref. 2); they have two similar and very strong binding sites for Fe(III), together with two associated anion binding sites. Fragmentation studies on various transferrins[3-6] have shown that the polypeptide chain is composed of two domains formed from the N-terminal and C-terminal halves of the polypeptide chain. Each domain contains one metal binding site. The marked sequence similarities which exist between the two halves may reflect a doubling of an ancestral structural gene during the phylogenetic development of the protein[2,7]. Preliminary crystallographic investigations of diferric rabbit plasma transferrin have been reported from this laboratory[8]. We now report initial studies of the X-ray structure determination of diferric rabbit plasma transferrin which have led to a 6-Å resolution electron density map.

The protein crystallises in the space group $P4_12_12$ or the enantiomorph, with $a = b = 127.5(3)$ Å, $c = 145.4(3)$ Å, and one molecule per asymmetric unit. The native crystals are grown within the temperature range of 4–8 °C; at higher temperatures

0028-0836/79/370157—02$01.00

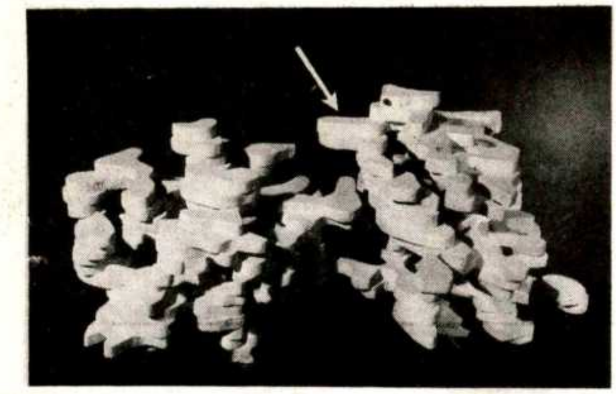

Fig. 1 A balsa wood model of electron density taken to represent one molecule of diferric rabbit plasma transferrin. The bilobal nature of the molecule is clearly seen and the arrow indicates the region of high electron density in the right hand lobe which may be α-helix. The prominent cleft in this lobe lies immediately below this region. The common platinum/mercury site is at the top of the left hand lobe.

they dissolve. Sixty-eight per cent of the crystal volume is occupied by solvent. The crystals are unstable in the absence of the mother liquor and derivatives were prepared by soaking the native crystals in solutions of heavy atom reagents in the mother liquor. The soaking conditions for the three derivatives used to produce the map are given in Table 1.

X-ray diffraction data for an octant of reciprocal space were collected on a Hilger and Watts Y290 automated four-circle diffractometer for the native crystals and three isomorphous derivatives. The diffractometer was equipped with a helium path, and a low-temperature device and Ni-filtered copper radiation were used throughout. Data were collected at 5 °C using ω-step scans. Three or four crystals were required per data set and intensities were estimated by a 'moving window' technique[9]; absorption corrections were made according to the method of North *et al.*[10].

Difference Patterson syntheses computed with ΔF_{iso}^2 (where ΔF_{iso} is the isomorphous difference) as coefficients enabled two major heavy atom sites to be located for the mercury derivative and one site for the platinum derivative. Only a partial interpretation of the uranyl map was possible at this stage. The three major uranyl sites were located from difference maps computed with protein phases obtained by multiple isomorphous replacement using the refined mercury and platinum positions. In addition, the heavy atom positions of the mercury and platinum derivatives were checked by the use of cross-difference Fourier syntheses based on single isomorphous protein phases from the uranium positions.

For each derivative the heavy atom coordinates and relative occupancies were refined against ΔF_{iso} for the centric reflections. Isotropic temperature factors were held constant at a value of 20 Å. Difference electron density maps were computed with coefficients $(\Delta F_{iso} - F_{Hcalc})e^{i\alpha_{Hcalc}}$ (where F_{Hcalc} and α_{Hcalc} are the calculated amplitude and phase of the heavy atom structure factor), but only revealed significant minor sites for the uranyl derivative.

The final heavy atom parameters and R factors are presented in Table 2. Protein phases were calculated from these parameters using the method of multiple isomorphous replacement with all three derivatives in space group $P4_12_12$.

Table 1 Derivatives used to produce the electron density map

Heavy-atom reagent	Time of soaking	Concentration	Method
Potassium chloroplatinate	36 h	7 mM	Direct soaking
Mercuric chloride	24 h	8 mM	Dialysis cell
Uranyl acetate	9 d	10 mM	Dialysis cell

Data collected to 6 Å.

Table 2 Heavy atom parameters and refinement statistics

Site	x	y	z	Z	B(Å^2)
Mercuric chloride					
1	0.487	0.125	0.178	0.086	20
2	0.032	0.278	0.185	0.046	20
		R(centric) = 0.61			
Potassium chloroplatinate					
1	0.024	0.285	0.184	0.063	20
		R(centric) = 0.58			
Uranyl acetate					
1	0.307	0.257	0.090	0.032	20
2	0.214	0.495	0.090	0.029	20
3	0.633	0.391	0.013	0.020	20
4	0.756	0.066	0.069	0.010	20
5	0.458	0.315	0.075	0.014	20
		R(centric) = 0.62			

x, y, z are the heavy atom fractional co-ordinates. Z is relative occupancy. All site occupancies are on the same arbitrary scale. $\langle|\alpha_P - \alpha_H|\rangle$, the mean absolute difference between the protein and heavy atom phase angles, is 86.9°, 89.3° and 90.7°, respectively, for mercuric chloride, potassium chloroplatinate and uranyl acetate.

The mean overall figure of merit for the 3,226 reflections is 0.50.

The 'best' phases and figures of merit[11] were used to calculate a 6-Å resolution electron density map. This map shows a well defined volume of high electron density with approximate maximum dimensions of 95 × 60 × 50 Å. This is represented by a balsa wood model (Fig. 1) which defines the molecular boundary. The high solvent content of the crystals and the low salt concentration of the liquid of crystallisation proved useful in this respect. The model shows that the molecule consists of two lobes of roughly equal size. The major axes of these lobes are inclined at about 30° to one another and their total volume is consistent with a protein content of about 30% in the crystal. All the heavy atom sites lie close to the surface of the molecule. Four of the uranyl sites and the major mercury site are on one lobe, and the remaining uranyl site and the common platinum and mercury site, which may correspond to the position of a methionine residue, are on the second lobe. The former lobe exhibits a pronounced cleft in the region of the join between the two lobes and close to this feature there is a column of high electron density which could be α-helix. On the opposite side of this same lobe another strong region of electron density may prove to be β-sheet at higher resolution. The second lobe also has a cleft, although less pronounced, close to the join.

The two lobes of the molecule may correspond to the two domains, each containing an iron binding site, proposed from fragmentation studies. However, the locations of the iron binding sites and the arrangement of amino acid residues in the diferric rabbit plasma transferrin molecule must await study at higher resolution. The collection of X-ray data to 3.0 Å resolution, the practical limit of the diffraction pattern using conventional sources, is now in progress.

We thank the MRC for providing support for B.G. and J.L.W. and the SRC. for supporting C.H.

applied excellence

Advanced techniques in routine use at The Radiochemical Centre

Described below are just two examples of the many up-to-date techniques, which have been pioneered or applied for routine use at The Radiochemical Centre. These developments are part of our constant endeavour to maintain our position at the forefront of the specialised field of tracer methodology, so that we can continue our supply of radiochemicals of the highest quality and technical specifications.

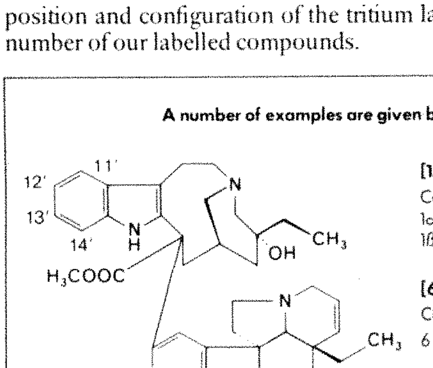
Distribution of labelling in tritium compounds

Modern techniques for the production of tritiated compounds are more sophisticated than those used in the early days of tritium labelling, and produce compounds labelled in specific positions rather than generally labelled. Nevertheless, it is necessary for many tracer applications of tritium compounds to know the *precise* position and configuration of the tritium labels. Traditional chemical methods of doing this are tedious and time consuming and subject to considerable error, and so the routine supply of such information has until recently not been possible.

The Radiochemical Centre, in collaboration with the University of Surrey, has developed over the past eight years the technique of tritium nuclear magnetic resonance (tnmr) spectroscopy for this purpose. This method is much quicker and more accurate than the traditional chemical or biochemical methods for determining distribution of tritium labelling.

It is now used routinely to establish the distribution of tritium labelling produced by the usual methods of tritiation employed at The Radiochemical Centre. We supply accurate details as to the position and configuration of the tritium labels for an increasing number of our labelled compounds.

A number of examples are given below:



[G-^{3}H]VINBLASTINE
Code TRK.507
17 .... 44% 11' 8%
12',13' .... 46% 14' 2%

[1β, 2β(n)-^{3}H]TESTOSTERONE
Code TRK.162
1α .... 5.9% 2α 8.2%
1β .... 46.0% 2β 39.9%

[6-^{3}H]BENZO[a]PYRENE
Code TRK.501
6 .... >95% 1 .... <5%

D-[2-^{3}H]GLUCOSE
Code TRK.361
2(α) .... 40% 2(β) 60%

L-[3,4(n)-^{3}H]VALINE
Code TRA/K.533
2 .... 8% 4 .... 64%
3 .... 28%

High performance liquid chromatography (HPLC)

This relatively new development of column chromatography is carried out using high efficiency microparticulate column packings of closely defined size.

Chromatography is carried out under pressure to ensure good flow rates and reduce diffusion of separated compounds. Dead volumes are kept to an absolute minimum. The result is that many separations can be carried out more quickly and with better resolution than with previously used chromatographic methods such as thin-layer chromatography or conventional column chromatography.

Work aimed at developing the applications of this method to radiolabelled compound separations is still in progress, but The Radiochemical Centre is already using the technique in many of its production processes, and in analytical applications. The result is purer compounds for the customer and greater efficiency of working.

The example illustrated below illustrates the clear superiority of HPLC when used as an analytical tool. The mixture used comprised the tritium labelled mono-, di- and triphosphates of adenosine, cytidine, guanosine and uridine, and all are clearly separated in the HPLC system.

reviews

Shaping psychology

O. L. Zangwill

Pioneers of Psychology. By R. E. Fancher. Pp. 397. (W. W. Norton: New York, 1979.) $15.95.

THE author tells us in his Preface that this book is about "the lives and works of some of the people who have shaped the modern science of psychology." Although there are still some people who hold, with William James, that psychology is less a science than the hope of a science, it can safely be said that the people Dr Fancher writes about, whether they were primarily philosophers or physicists, physiologists or physicians, have had much to do with the shaping of psychology as we know it today. His account even extends to a few, such as Wilhelm Wundt, who were essentially experimental psychologists even if the posts they occupied fell within other academic disciplines, and to two contemporary "pioneers", Jean Piaget and B. F. Skinner. Nevertheless, it is essentially an outline, somewhat superficial though extremely readable, of the background of modern psychology.

The opening chapter, on Descartes, sets the tone of the book. This may be described as a blend of thumb-nail biography and the history of ideas. As Dr Fancher right points out, Descartes' knowledge of anatomy was amateur even by the standards of his time and his physiology was mostly wrong. Nevertheless, his concept of reflex action and the mechanistic model of the nervous system which it inspired has largely animated the growth of neurophysiology and provided experimental psychology with its basic philosophy. True, Descartes' resolution of the mind-body problem has left many people unsatisfied but it has nevertheless remained an influential belief not only among philosophers but many scientists too. Cartesian dualism may well be wrong but it is inseparable from the evolution of modern science.

The next chapter is headed "The Physiology of Mind" and traces the development of our ideas about brain function from Gall's phrenology to present-day neurosurgery. Inevitably, Dr Francher deals at some length with Pierre Flourens, whose work on the effects of brain lesions on behaviour in animals did much to discredit phrenology and promote the view that sensory and motor functions lack discrete representation in the cerebral cortex. As has often been pointed out, his conclusions in many respects anticipated those of Karl Lashley over a century later. Indeed it was the clinicians rather than the experimental physiologists who changed the whole climate of localisation theory. Following the claims of Broca and others that supposedly circumscribed disorders of language might follow localised cerebral lesions, a kind of neo-phrenology evolved envisaged in terms not of bumps but of brain centres. Although the concept of a brain centre was soundly based on the theory of reflex action, it became only too readily contaminated by psychology. The result was a new mythology of cerebral functions bearing little relation either to the mechanisms of nervous action or to the realities of human behaviour.

It can perhaps be said that neurology is now working towards a less extreme conception of the cerebral localisation of psychological function. Although focal deficits resulting from cortical lesions have been charted with a very fair degree of precision, we still lack any clear conception of the relation of deficit to normal function and the extent to which the machinery of the brain may be inferred from studies of its breakdown. Interestingly, Dr Fancher views Penfield's work on the effects of cortical stimulation in conscious man as the latest and most decisive phase in the localisation controversy. Brilliant indeed as was Penfield's work, it cannot really be said to have made a major theoretical contribution to solution of the mind-body problem. Indeed, Roger Sperry's work on 'split-brain' man might seem to offer greater hope of a fresh consideration of the physical basis of mind and consciousness. It is a pity that Sperry's work fails to find mention in Dr Fancher's book.

We then come to two chapters mainly concerned with the origins of modern experimental psychology. The first deals principally with studies of human sensation and perception and centres on Helmholtz: the second with Wilhelm-Wundt, whom the author places in sharp contrast with William James, somewhat to Wundt's disadvantage. In connection with Helmholtz, Dr Fancher does well to place stress on the Kantian influence on his thinking, which his strongly empiricist bias has caused many to disregard. It is evident, for example, that, although Helmholtz laid great emphasis on the role of experience and learning in human perception, more especially the perception of space, he treated sensation as basically innate. Whether we regard Helmholtz as a physicist, a physiologist or a psychologist is irrelevant. Though he did not himself wish to be regarded as a psychologist, there can be no doubt that, without him, human experimental psychology would never have found its feet.

This inevitably brings us to Wundt, who is remembered as the founder of the first laboratory in the world exclusively dedicated to experimental psychology. Indeed it celebrates its centenary this year. James was sceptical as to its promise: As he tartly remarked, "there is little of the grand style about these new prism, pendulum and chronograph philosophers." Yet, to give him his due, Wundt did try to bring together psychophysical studies and the physiology of the senses, and his work enabled experimental psychology to emerge as an independent discipline. Yet James has perhaps been proved right in so far as experimental psychology, though nowadays respectable, is seldom scintillating.

The scene now shifts to a very different theme, remote from the University but close to the consulting room. This is the theme of psychological medicine, and its origins are traced to the early hypnotists beginning with Mesmer and culminating in Freud. On Mesmer, Dr Fancher has disappointingly little new to tell us. In particular, he throws no light on Pattie's contention that his doctoral thesis was cribbed almost word-by-word from a thesis by one Richard Mead, an obscure Irish physician. This claim, if true, detracts considerably from the more sympathetic judgements of Mesmer's personal integrity advanced by several recent biographers. On Freud, the subject of an earlier book by the same author, Dr Fancher is knowledgeable and sympathetic. His chapter is of considerable value in stressing the importance of much of Freud's earlier work, in particular his draft project for a scientific psychology, written in 1895 but published only several years after his death, and the early case studies on hysteria. His book on *The Interpretation of Dreams* rightly receives high commendation. It is disappointing, however, that Dr Fancher sees no obvious way whereby the insights of psychoanalysis might be linked with the sterner disciplines of the neurosciences.

The only reference to British psychology is a chapter on Francis Galton and the psychology of individual differences. This once again covers familiar ground and it is a pity that a recent biography by D.W. Forrest, altogether more digestible than Pearson's monumental three volumes, fails to find mention. Fancher's short account is useful in stressing Galton's fascinating studies of visual imagery and word-association, which have been relatively neglected in recent years, and he deserves credit for not getting too embroiled in the nature-nurture controversy, so productive of emotion though hardly of wisdom in contemporary psychological discussion.

The last two chapters bring us closer to the modern scene. The penultimate chapter gives an account of Pavlov's work followed by a short outline of the history of behaviourism. Although the account of J. B. Watson's life and work is not without historical interest, it fails to bring out fully how little behaviourism, in its early days at least, owed to Pavlov (it was more influenced by his rival Becterev); nor how greatly Pavlov himself detested behaviourism, which he regarded as little better than the mentalistic psychology it replaced. The importance of Lashley as a co-founder of behaviourism is insufficiently stressed. The final chapter contrasts Jean Piaget with B. F. Skinner, both described as modern pioneers. Only the future will show.

Although much of this book has been compiled from secondary sources and makes no advance on the widely accepted version of the history of experimental psychology which we owe to the late E. G. Boring, this book can be recommended for its thoughtful and well-written account of some important threads in its more recent phases of development. It is only perhaps in the sections dealing with German psychology that the author fails in some measure to catch the spirit of the age, due to the probability that he is unable to read German. Although it may be true that English is now the accepted language of European science, the historian of science would do well to acquire at all events, a reading knowledge of the mother tongue of European scientists. □

O. L. Zangwill is Professor of Experimental Psychology at the University of Cambridge, UK.

Free radical chemistry

Radicals. By D.C. Nonhebel, J.M. Tedder and J.C. Walton. Pp. 200. (Cambridge University Press: Cambridge, 1979.) Hardback £14; paperback £5.50.

To cover adequately the many important aspects of free radical chemistry in approximately 200 pages, even at the undergraduate level, is an impossible task. This book makes an excellent attempt at the impossible.

The book is aimed at honours and post-graduate chemists but should also be useful to chemists at all levels in need of background information on radical chemistry. The coverage is wide-ranging although the depth of treatment is variable. Almost no original references are quoted but there is an extensive list of books and reviews for each chapter collected at the end of the book.

Not unexpectedly, in view of the authors' research interests, the chapters entitled "Radical transfer reactions" (18 pages), and "Radical addition reactions" (22 pages) are particularly well done and are a first-class source of facts and current concepts of radical mechanisms. The chapter on "Radicals in biological systems" (15 pages) is also admirable and timely, as this is a growth area in free radical chemistry. Indeed, I would have preferred if this chapter had been somewhat longer, perhaps at the expense of part of that on "Radical polymerisation" (13 pages). The chapter devoted to "Stereochemistry of free radicals" (9 pages) is also most welcome, as this subject usually receives little attention in textbooks at this level. Awareness of the shape and preferred conformations of radicals is essential if a proper understanding of radical reactions is to be achieved.

Oxidation and reduction in free radical chemistry is a notoriously difficult subject to cover because the terms themselves seem to mean different things to different chemists and the subject matter does not lend itself easily to uniform treatment. Because of this the 15-page chapter on this subject seemed rather short and I would have preferred to have seen a fuller account given.

The book also gives brief introductions to the use of electron spin resonance spectroscopy and CIDNP, and there are chapters on combustion, radical reactions, homolytic aromatic substitution, radical rearrangements, and radical displacement reactions. All of these are sound, although perhaps not quite as good as some of the chapters mentioned earlier.

In summary, I can fully recommend this book as a compact account of present-day free radical chemistry. My criticisms of it are minor and are essentially restricted to the space allocation given to the various subjects.

A.R. Forrester

A.R. Forrester is Senior Lecturer in Chemistry at the University of Aberdeen, UK.

Reptilian ear

The Reptile Ear: Its Structure and Function. By Ernest Glen Wever. Pp. 1024. (Princeton University Press: Princeton, New Jersey, and Guildford, UK, 1979.) $50; £31.30.

The Reptile Ear is a monumental work of outstanding importance, representing more than 25 years of effort by a distinguished scientist. Much of the work described in this book has not been published before.

Detailed studies of the external, middle, and internal ears of 247 species of reptiles were investigated, including 186 species of lizards belonging to 16 families; 19 species of snakes; 14 species of amphisbaenians; 24 species of turtles; 3 species of crocodilians; and the single existing species of rhynchocephalians.

Wever's investigations were both anatomical and physiological, and this greatly enhances the significance of this work. The anatomical studies were carried out by means of serial celloidin sections. It is remarkable that Wever achieved such excellent and accurate detail by a light microscopic method, as his structural interpretations have been corroborated by scanning electron microscopic studies made by other workers.

Wever presents all his anatomical findings by drawings of excellent quality. It would have been helpful to others, however, to have at least some sections represented by photomicrographs.

A great deal of quantitative structural information is presented, such as papilla basilaris lengths, widths, hair cell numbers, basilar membrane width, numbers of rows of hair cells, and so on. Of particular interest is Wever's descriptions and classifications of various types of tectorial membranes.

Wever's evaluation of the functional capacity of these many ears is by use of the cochlear potential method. In many cases, Wever demonstrates increased functional capacity to be related to structural complexities. Such, however, is not always the case.

A great deal of attention is also directed to discussions of the mechanics of hair cell excitation, a problem of salient importance and interest at the moment. The concluding chapter on the biological and evolutionary significance of the reptilian ear is somewhat brief and perhaps properly conservative. Throughout the text, however, Wever indicates structure in relation to phylogeny and evolution. That the reptiles "experiment" widely with many ear components has been well demonstrated and is one of the reasons for the great interest in the reptilian ear.

Oxford Books for Students

Physical Chemistry

P. W. Atkins

'It is a book of its time not only in content and outlook but in format and style too . . . . could well become a milestone in the development of text books of physical chemistry.' *Chemistry in Britain.* 'An important and original work.' *Education in Chemistry.* 'The author is to be congratulated on the production of such a good text and the publishers for its presentation at a price within the reach of students.' *British Book News.* £17.50 paper covers £7.95

Solutions Manual for Physical Chemistry

P. W. Atkins

This manual contains the author's detailed solutions of almost every one of the 1,060 problems contained in his textbook *Physical Chemistry.* It will be invaluable both to the instructors and lecturers who have adopted the parent text and to the students who use it themselves. Illustrated paper covers £4.50

Elementary Information Theory

D. S. Jones

Information theory is important to the designers of communication networks and electronic computers, and includes aspects of cryptography and linguistics. This book forms a one-term course for undergraduates in science and engineering. It begins with a short description of the relevant notions from probability theory. Then the quantity of information in a message is defined and its properties developed. The coding of messages is considered, followed by treatment of channel capacity, error-correcting codes, and continuous signals. £11 paper covers £4.95 *Oxford Applied Mathematics and Computing Science Series*

Biochemistry

Frank Bradley Armstrong and Thomas Peter Bennett

This book is an introductory text for first-year undergraduates studying biology, biochemistry, or chemistry at degree level. The topics treated include water as the solvent of life, cells as the biological units of molecular organization, proteins, carbohydrates, liquids and membranes, the basics of human nutrition, and hormones. £14

Thermodynamics and Statistical Mechanics

P. T. Landsberg

The basic ideas and mathematical formulations of thermodynamics are presented here in a concise and modern way. Topics covered include: negative temperatures; negative heat capacities; special and general relativistic effects; black hole thermodynamics; gravitational collapse; energy conversion problems; and efficiencies including simple heat pump theory. £8.50

The Solid State

An Introduction to the Physics of Crystals for Students of Physics, Materials Science, and Engineering

H. M. Rosenberg

The topics covered include basic crystal structure, diffraction of waves, dislocations, specific heat, phonons, thermal and electrical conductivity, the physics of p–n semiconductor junctions, and magnetic and dielectric properties. For the second edition a chapter on superconductivity has been added. £5.50 paper covers £2.95 *Oxford Physics Series*

Physical and Engineering Science for Technicians, Level I

R. J. Besanko and T. H. Jenkins

This new version of *General Engineering Science* is designed to cover the units in physical science and engineering science at Level 1 for students taking TEC Certificate and Diploma Programmes. Some additional material is included to satisfy college-devised units, and the book is also suitable for other courses at this level. Paper covers £2.95

Scientific Models and Man

The Herbert Spencer Lectures, 1976

Edited by Henry Harris

In these lectures a group of distinguished men from different disciplines describe how current work in their own subject is changing their view of the world. Scientific models have been enormously influential in transforming the way in which we look at ourselves and at the universe: this book gives some indication of the way the world is going to look tomorrow. £3.25

New books from CAMBRIDGE

Paperback edition

The Pursuit of Nature

Informal Essays on the History of Physiology

SIR ALAN HODGKIN, SIR ANDREW FIELDING HUXLEY, W.S. FELDBERG, W. A. H. RUSHTON, R. A. GREGORY and R. A. McCANCE

'It is an enjoyable book for the student, opening the door into living history and introducing him to all the greats, not only these six but also their colleagues and their teachers who constitute the very backbone of physiology.' *Nature*

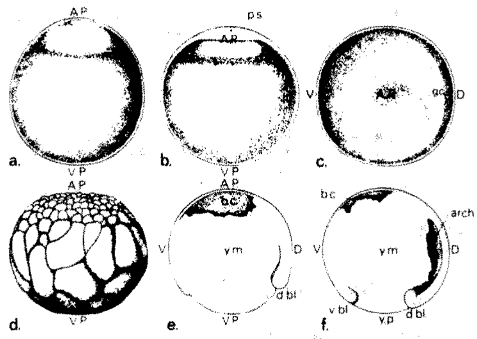
Still available in hard covers **Paperback £2.95 net**

Cellular Radiobiology

T. ALPER

This account is concerned with the more basic aspects of the lethal effects of radiation on all kinds of cells. These effects are subject to extensive modification by physical, chemical and biological factors and also by the capacity of cells to repair damage. Dr Alper devotes considerable attention to the way in which modifying factors interact with each other, and points the way to future research. This stimulating account will be read by students and professionals in radiology, radiotherapy and nuclear research and by all those using radiation as a tool in their research.

Hard covers £18.00 net
Paperback £5.95 net



Primordial Germ Cells in the Chordates

P. D. NIEUWKOOP and L. A. SUTASURYA

This book deal with the origin and cellular differentiation of the primordial germ cells during the first phases of embryonic development of the chordates, and their migration to their ultimate location in the gonadal anlagen. Among the chordates there are differences concerning the place and mode of origin of these cells which may reflect different phylogenetic histories. This account will be of great interest to research workers and teachers in developmental, reproductive and evolutionary biology.

Developmental and Cell Biology 7 **£14.50 net**

Introduction to the Theory of Solid Surfaces

F. GARCIA-MOLINER and F. FLORES

A self-contained account of the theory of surface physics which draws together many results previously scattered in research journals. No previous knowledge of surface physics is assumed, and the reader is led from first principles to elementary analysis and then to the level of current research literature. This monograph is intended for post-graduate students and research workers requiring a systematic introduction to the field.

Cambridge Monographs on Physics **£27.50 net**

The Forces of Nature

P. C. W. DAVIES

Written in the same readable style as *Space and Time in the Modern Universe,* this book presents an authoritative account of the exciting developments in sub-atomic physics. The reader will learn about antimatter, the creation and destruction of particles, the evidence that the celebrated quarks are fundamental building blocks for matter, and the promising signs that a unification of the basic forces of nature is at hand. This exciting book will appeal to everyone with an interest in the forces that govern the Universe.

Hard covers £12.00 net
Paperback £4.25 net

Models of Disorder

The theoretical physics of homogeneously disordered systems

J. M. ZIMAN

The physical and chemical properties of disordered systems such as liquids, glasses, alloys etc. are explained nowadays by theories based on a variety of mathematical models. This book describes these models and the various mathematical theories by which the observable properties are derived. Professor Ziman examines an unusually wide range of systems and phenomena, showing underlying connections between diverse topics. This book will appeal to research workers and advanced students in theoretical and experimental physics.

Hard covers £25.00 net
Paperback £12.50 net

Paperback edition

The Tropical Rain Forest

P. W. RICHARDS

This volume, first published in 1952 and reprinted for the fifth time in 1976, has remained an important standard work and is now made available as a paperback. It gives a comprehensive account of the ecology of rain forest vegetation. In view of the growing concern about the preservation of rain forests this book should be of interest not only to botanists and foresters, but also to ecologists, geographers, zoologists and conservationists.

Still available in hard covers **Paperback £9.95 net**

CAMBRIDGE UNIVERSITY PRESS

Cambridge London New York Melbourne
Further details of the books are available on request from
Cambridge University Press, P.O. Box 110,
Cambridge CB2 3RL.

The author has been careful to describe his working methods in great detail. This information should be of great value ot others.

Numerous recent studies have proved the great value of the reptilian ear as an object of study for investigation of the vertebrate auditory system. Wever's compendium will serve as a valuable and necessary reference and source book for future investigations. **Malcolm R. Miller**

Malcolm R. Miller is Professor in the Department of Anatomy, University of California School of Medicine, San Francisco, California.

African mammalogy

Ecology of African Mammals. By M.J. Delany and D.C.D. Happold. Pp. 434. (Longman: London and New York, 1979.) £25.

THIS book, the third contribution to Longman's Tropical Ecology Series covers Africa south of the Sahara. All aspects of the ecology of African mammals, both large and small, are considered resulting in a big book full of concentrated information. The tendency to categorise the text into sections and sub-sections does not make for easy reading but the approach will no doubt be appreciated by students wishing to note essential points. The book is divided into four parts and consists of thirteen chapters. The first part gives a comprehensive account of African mammals in an historical setting and the second concerns the biotic zones dealing in turn with rain forests, savannas, arid zones and mountains. The third part considers life histories, behavioural ecology, physiology and population dynamics; and the fourth section, consisting of only one chapter, examines the interactions between mammals and man.

The book, which is extremely well illustrated, covers the ground admirably and the authors have made a very thorough job of their survey of the literature. They have tried to give a balanced account, which is not an easy task considering that the coverage of the field by research workers is far from even. On the whole, they have selected wisely and have not been biased by their own particular research interests, which are mainly in small mammals. Their account of the large mammals, being essentially a literature review, inevitably lacks something of the critical insight which an active worker in the field would provide. A few of the examples could have been better chosen, for example Rwenzori National Park (p. 113) is not very representative of its region in terms of the number of large mammal species in view of the fact that six more ungulate species occur in a game reserve less than 100 km to the east. It is also unfortunate that the work of Dasmann and Mossman, now some 20 years old, should be quoted in support of game ranching because the yields proposed were hopelessly optimistic and could not have been sustained for long.

There are few errors in this excellent book and none of great significance. It will prove extremely useful as a university text particularly in Africa but also in Europe and America for, given the rich mammalian fauna of Africa, it can serve as a general textbook of mammalogy. Research workers will also find it of value as a reference book. **S.K. Eltringham**

S.K. Eltringham, formerly Chief Research Officer of the Uganda National Parks, is now Lecturer in Applied Biology at the University of Cambridge, UK.

Modern ionospheric physics

Inospheric Techniques and Phenomena. By A. Giraud and M. Petit. Pp. 264. (D. Reidel:Dordrecht, The Netherlands, Boston and London, 1978.) Dfl.85; $38.

IONOSPHERIC physics has rapidly evolved after the International Geophysical Year (1957-58), from the old days during which traditional ionospheric sounders were the main tool, to the new era during which a number of new powerful tools have been introduced to measure basic ionospheric quantities. As one of those who is aware of such progress and yet has difficulty in catching up on modern literature as a non-specialist in this particular field, I am delighted to have this book. It presents an overall view of the new ionospheric physics. In particular, the ionosphere is properly and accuratley recognized as an integral part of the solar-terrestrial system. In this sense, I feel that the title *Modern Ionospheric Physics* would have been more appropriate.

The book provides a well-balanced presentation of the subject, and will serve as a good textbook for a graduate level course in aeronomy as well as an important reference book for ionospheric physicists and magnetospheric physicists. The book will familiarise readers with all modern techniques in investigating the ionosphere, equipping them well in interpreting data taken from such techniques and also in understanding very recent and future articles in this particular field.

Ocean yearbook

Ocean Yearbook 1. Edited by Elisabeth Mann Borgese and Norton Ginsburg. Pp. 890. (Pacem in Maribus/International Ocean Institute/University of Chicago Press: Chicago and London, 1979.) £17.50; $25.

ELISABETH Mann Borgese, International Ocean Institute, Malta, and Norton Ginsburg, University of Chicago, are to be congratulated on getting their latest brainchild, the *Ocean Yearbook*, off the ground with its first edition, recently published. Although named a yearbook, the year in question has not been identified; however, the reports of the various organisations which appear in an Annex, cover 1976 and, in certain cases, to mid-1977.

Following a short Editors' Preface, *Ocean Yearbook 1* contains a series of excellent topical articles on Issues and Prospects; Living Resources; Non-living Resources; Transportation and Communication; Marine Science and Technology; Environment; Coastal Management; Military Activities; and Regional Development. These are followed by a number of appendices covering reports from organisations, selected documents and proceedings, a directory of institutions, tables related to the articles, and an index.

The *Yearbook* is a long-awaited product of the International Ocean Institute, Malta, which is described in the Preface as "an offspring of an initiative of the Center for the Study of Democratic Institutions in Santa Barbara, California, USA". Publication of an Ocean Yearbook is the logical outcome of the present greatly increased interest in the Oceans which has been kindled by the Third United Nations Conference on the Law of the Sea. It is therefore vitally necessary to follow the developments which are taking place at the Conference, as presented in an excellent critique of the Informal Composite Negotiating Text (1977) by Arvid Pardo, who, in 1967, speaking as the Ambassador of Malta to the United Nations General Assembly, was originally responsible for drawing the attention of the world's governments to the potential of the oceans and their importance to the future of mankind.

Although the key to most other activities in the oceans, there is only one article on Marine Science (and Technology), Perspectives on the Sciences of the Sea by Lord Ritchie-Calder, who sounds a well-justified note of warning in his final two paragraphs. As stated by Sir Francis Beaufort, Hydrographer of the Navy (1829-1855), "The natural tendency of men is to undervalue what they cannot understand". The editors, by their imbalance of content in favour of applied activities at the expense of basic science, are giving credence to this unfortunate tendency which is particularly prevalent today in the United Nations system and amongst the national aid agencies.

I would also suggest that the selected Documents and Proceedings, contained in Appendix B, should be restricted to "a selection of international agreements, legislation and proceedings of international conferences" which have been finalised. Despite its relevance to Arvid Pardo's article, I query the desirability of reproducing in full the UNCLOS Informal Composite Negotiating Text which had already been replaced by a revised edition before the Yearbook was published.

The errors I have noted are minimal. This is a well compiled and well edited publication. My main fear is that the editors have set their sights too high and will be unable to maintain their present standard and the sheer volume of information contained in the first edition; in any case, at yearly intervals as its name implies. I note only that in the bibliography to Lord Ritchie-Calder's article, Frye, P. is presumably Paul M. Fye, now President of the Corporation, Woods Hole Oceanographic Institution. I must also inform Tom Busha and James Dawson that the only flaw I can find in their most informative article on that excellent organisation IMCO is that the Hydrographic Department of the Admiralty was founded in 1795 (not 1759) when Alexander Dalrymple, Hydrographer to the East India Company, was appointed the first Hydrographer of the Navy.

Desmond P.D. Scott

Desmond P.D. Scott is Secretary of the Intergovernmental Oceanographic Commission, Unesco, Paris.

Magnetohydrodynamic stability

MHD Instabilities. By G. Bateman. Pp. 263. (MIT Press: Cambridge, Massachusetts, and London, 1979.) £15.75; $22.50.

DESPITE the generality of its title this book addresses rather specifically the question of magnetohydrodynamic stability as it relates to the currently most promising approach to magnetic confinement of fusion plasmas, the Tokamak. This is perhaps surprising in a book the content of which is primarily didactic. However, the result is a relatively compact book which maintains coherence and covers much ground that is of fundamental importance to the subject.

Dr Bateman begins from a virtually axiomatic statement of the governing MHD equations, moderated by a brief enumeration of effects neglected by the MHD formulation. He then proceeds by way of an illustrative chapter on the Rayleigh-Taylor Instability to a development of the theory of equilibrium and linear stability and a derivation of the energy principle. Cylindrical and toroidal geometries are treated and then high beta questions. Non-linear evolution and resistive instabilities each have a chapter. All this theory is sandwiched between two experimental chapters: the first serving as an introduction and motivation, the last as a comparison between theory and experiment.

Although the mathematical details are included in several cases, the emphasis throughout is on understanding the physical concepts. It is refreshing to read so clear an exposition of the physics in a subject which is so often obscured by a tangle of algebra or mystified by the ubiquitous computer 'simulation'. Not that these are absent, but they are treated with a light, often qualitative, touch, drawing frequently on references to the literature. This approach may feel unsatisfactory for some and it disqualifies the book from being a true reference volume or probably even a self-contained text. However, it greatly enhances its value as an introduction to the subject, and the references (many commendably recent) are there for those who want something heavier to chew on. The provocative questions scattered through the text are great fun.

A serious attempt is made to relate the theory to the experimental context but the connection is not always made really clear. This reflects partly the state of the subject but also an inherent ambivalance in the book between a presentation of fundamentals and a review of current Tokamak MHD research. Given that problem, it seems a pity that Dr Bateman did not choose a rather broader spectrum of applications, to include at least other related toroidal plasma confinement schemes, such as the reversed field pinch in which MHD instabilities are of at least as great importance as in Tokamaks.

MHD Instabilities serves as an excellent introduction for students and researchers in magnetic confinement MHD theory. Its treatment of Tokamak-related problems should prove of great value to the growing numbers in Tokamak research, many of whom are not directly involved in MHD research as such but for whom MHD stability is vital in determining the plasma environment.

I.H. Hutchinson

I.H. Hutchinson is Principal Research Scientist at the Plasma Fusion Center/Frances Bitter National Magnet Laboratory, Massachusetts Institute of Technology, Cambridge, Massachusetts.

New Monographs

Transfer RNA: Structure, Properties, and Recognition

Monograph 9A

Edited by **Paul Schimmel,** *Massachusetts Institute of Technology;* **Dieter Söll,** *Yale University;* and **John Abelson,** *University of California, San Diego*

1979, 624 pp. (approx.) 0-87969-128-X
Cloth, $60 LC 79-17143 CIP

Transfer RNA: Biological Aspects

Monograph 9B

Edited by **Dieter Söll,** *Yale University;* **John Abelson,** *University of California, San Diego;* and **Paul Schimmel,** *Massachusetts Institute of Technology*

1979, 608 pp. (approx.) 0-87969-129-8
Cloth, $60 LC 79-17578 CIP

The aim of these two volumes is to be the definitive reference work on tRNA. The volumes come at a time when considerable information on tRNA has been obtained and when there is a great need to organize and concisely summarize this information.

As a text, these books are ideally suited for use in a nucleic acids seminar course. As reference sources for all students in the fields of biochemistry and biophysics, they will be basic acquisitions to professional libraries.

Special Offer on Individual Prepaid Orders: $96 for both volumes if purchased as a set. Each volume will be shipped separately immediately upon publication. Offer limited to prepaid orders from individuals (not available to libraries, booksellers, institutions). Send personal check or money order.

CONTENTS

Primary Structures and Sequencing of tRNAs
Sequencing mt tRNA (RajBhandary); Primary structure of tRNAs (Dirheimer); [^{3}H]Borohydride in RNA analysis (Randerath); Modified nucleosides in tRNA (Nishimura)

Crystal Structure Analysis of tRNAs
Crystal structure of yeast tRNA^{Phe} (Kim); tRNA structure analysis (Rich); Structure and function of tRNA (Sundaralingam); Structure of initiator tRNA (Schevitz); Structure of tRNA^{Gly} (Wright)

tRNA Structure and Dynamics in Solution
Physical studies of tRNA in solution (Crothers); NMR studies on tRNA (Reid); FTNMR: Structure and dynamics (Johnston); Solution structure of tRNA (Potts)

Aminoacyl-tRNA Synthetases
Aminoacyl-tRNA synthetase structures (Hartley); Molecular enzymology of tRNA^{Trp} synthetase (Kisselev); Editing mechanisms (Fersht); tRNA^{Trp} and tRNA^{Tyr} synthetases (Winter); Recognition and proofreading (Cramer); Methionyl-tRNA synthetase (Blanquet)

Recognition of tRNAs by Proteins
tRNA recognition by synthetases (Schimmel); Protein tRNA recognition (Schulman); tRNA synthetase interactions (Ebel); Specificity in tRNA aminoacylation (Hecht)

tRNA Interactions with Ribosomes
tRNA—ribosome interactions (Cantor); Ribosome structure and tRNA binding sites (Lake); Affinity labeling of ribosome sites (Kuechler); tRNA–ribosome interaction (Wintermeyer); Structural transitions in tRNA (Möller); Isomers of aminoacyl-tRNA (Sprinzl); Analogs of lysyl-tRNA (Johnson); Accuracy of aminoacyl-tRNA (Yarus)

Appendices
Sequences of tRNAs (Sprinzl); Structures of modified nucleosides (Nishimura); Characteristics of aminoacyl-tRNA synthetases (Schimmel, Söll)

CONTENTS

tRNA Biosynthesis
tRNA synthesis (Mazzara); Processing of spacer tRNAs (Lund); tRNA precursors in RNase P mutants (Shimura); Transcription and processing of tRNA precursors (Daniel); Purification of processing nucleases using synthetic tRNA precursors (Ghosh); Interaction of RNase M5 with 5S rRNA (Pace); Processing of rRNA and tRNA (Apirion); rRNA and tRNA processing signals in rRNA operons (Young); Structure and removal of intervening sequences by an excision-ligase activity (Valenzuela)

tRNA Gene Arrangement
tRNA genes of *Drosophila* (Tener); 4S RNA gene organization in *Drosophila* (Elder); Localization of tRNA genes in *Drosophila* (Kubli); tRNA genes in rRNA operons (Morgan); Mapping of chloroplast tRNA genes (Steinmetz); *E. coli* tRNA gene organization (Rossi); Cloning of synthetic *su3*$^{+}$ tRNA genes (Ryan); Transcription and processing of tRNA genes (Cortese)

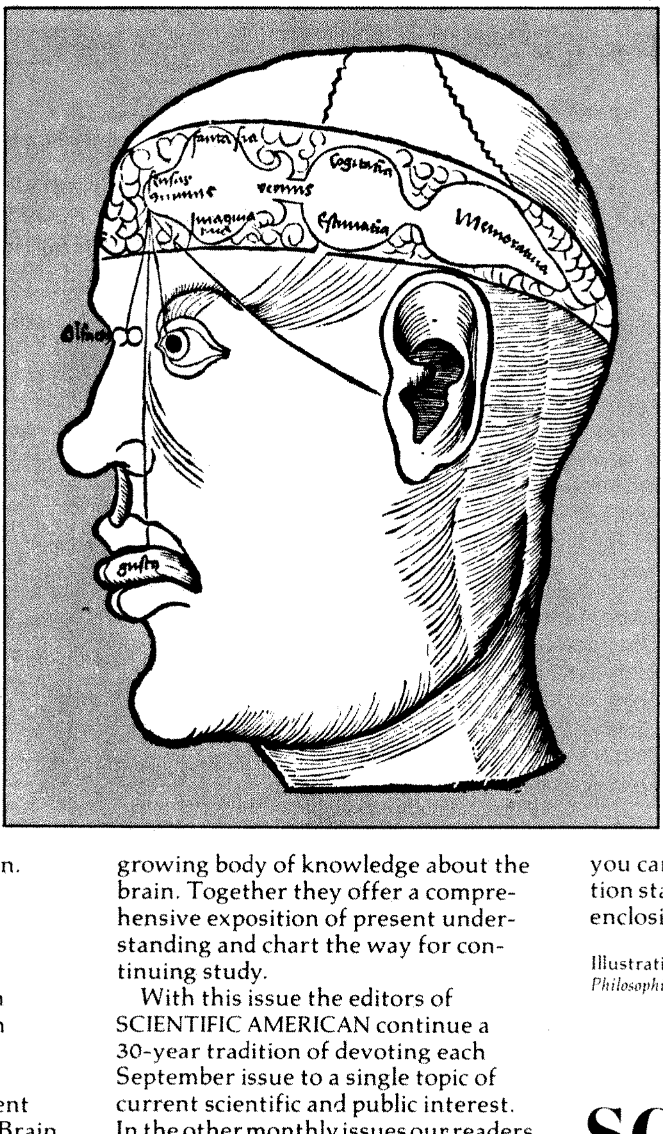
Supression and Coding
Genetics of tRNA suppressors in *E. coli* (Ozeki); Nonsense suppressor tRNAs (Piper); UGA suppressors in yeast (Kohli); Nontriplet reading (Atkins); UGA suppressor (Buckingham); i^{6}A-deficient tRNA (Laten); Temperature-sensitive suppressors (Oeschger); Codon recognition by tRNA^{Leu} (Goldman)

Other Roles of tRNA
Selective tRNA-rRNA binding (Yang); Aminoacyl-tRNA protein transferases (Soffer); tRNA-like structures (Haenni); tRNA regulatory roles reexamined (Umbarger); Branched-chain amino acid transport (Quay); *trp* operon attenuation (Eisenberg)

COLD SPRING HARBOR LABORATORY ▪ P.O. BOX 100, COLD SPRING HARBOR, NEW YORK 11724

Circle No. 18 on Reader Enquiry Card.

THE BRAIN is the single topic of the September issue of SCIENTIFIC AMERICAN



Is the brain a computer? What is the role of chemistry in brain function? Is the capacity of speech "hard-wired" into the brain? Where in the brain is the mind?

These are questions that will engage your interest in the September issue of SCIENTIFIC AMERICAN.

This issue does not, by any means, tell you "how the brain works." That remains one of the most alluring and baffling questions on the frontier of understanding. The convergence of work in many disciplines—from neurosurgery to linguistics—has begun to put that question, however, in ways that can yield answers.

The deep new knowledge about the brain, gathered at an accelerating rate in recent years, shows this organ to be marvelously designed and capacitated beyond the wonders with which it was invested by ignorant imagination.

Here are the articles:

- The Brain (Introduction)
- The Neuron
- Small Systems of Neurons
- The Organization of the Brain
- The Development of the Brain
- The Chemistry of the Brain
- Brain Mechanisms of Vision
- Brain Mechanisms of Movement
- Specializations of the Human Brain
- Disorders of the Human Brain
- Thinking about the Brain

Each of the authors of this issus has made significant contribution to the growing body of knowledge about the brain. Together they offer a comprehensive exposition of present understanding and chart the way for continuing study.

With this issue the editors of SCIENTIFIC AMERICAN continue a 30-year tradition of devoting each September issue to a single topic of current scientific and public interest. In the other monthly issues our readers enjoy a diversity of articles covering the full range of disciplines.

All the major advances in science of the past three decades have been reported in our pages by the scientists who have done the research. The collaboration of our editors in the preparation of text and illustration makes this work accessible to a steadily growing worldwide readership.

Our single-topic issue devoted to The Brain goes on sale at leading newsagents throughout the United Kingdom in the second week of September.

Or, you may wish to have the convenience of receiving SCIENTIFIC AMERICAN each month on subscription. At international rates, a one-year subscription is only £11 ($22); the two-year rate is £20 ($40) and the three-year rate is £27 ($55).

Use the coupon below to begin enjoying the diversity of articles in each monthly issue. You need send no money. We will bill you. But you can make sure that your subscription starts with the September issue by enclosing payment.

Recent scientific and technical books

Astronomy

BAITY, W.A., and PETERSON, L.E. (ed.). X-ray Astronomy. (Proceedings of a Symposium of the Twenty-first Plenary Meeting of COSPAR, Innsbruck, Austria, 29 May to 10 June 1978, including a Catalogue and Bibliography of galactic X-ray Sources.) (Advances in Space Exploration: COSPAR Symposium Series, Vol.3.) Pp. xvi + 558. ISBN-0-08-023418-6. (Oxford and New York: Pergamon Press, 1979. Published for the Committee on Space Research.) £47.50.

BRANDT, John C., and MARAN, Stephen P. New Horizons in astronomy. Second edition. Pp.xv + 614. ISBN-0-7167-1043-0. (San Francisco and Reading: W.H. Freeman and Company, 1979.) £9.60.

HAZARD, C., and MITTON, S. (ed.). Active Galactic Nuclei. (Based on the Proceedings of a NATO Advanced Study Institute, held at the Institute of Astronomy, University of Cambridge, August 1977.) P.vi + 317. ISBN-0-521-22494-2. (Cambridge, London and New York: Cambridge University Press, 1979.) £15.

KAUFMANN, III, Wlliam J. Planets and Moons. Pp.x + 219. ISBN-0-7167-1040-4. (San Francisco and Reading: W.H. Freeman and Company, 1979.) Hardcover £8; Softcover £3.95.

NACOZY, Paul E., and FERRAZ-MELLO, Sylvio (ed.). Natural and Artificial satellite Motion. Pp.xvi + 434. ISBN-0-292-75514-7. (Austin and London: University of Texas Press, 1979.) £17.50.

PASACHOFF, Jay M. Astronomy: From the earth to the Universe. Pp.xvi + 476 + 64 + xix. ISBN-0-7216-7112-8. Teacher's Guide. Pp.200. (Philadelphia and London: W.B. Saunders Company, 1979. np.

WESTERLUND, Bengt E. (ed.). Stars and Star Systems. (Proceedings of the Fourth European Regional Meeting in Astronomy, held in Uppsals, Sweden, 7-12 August, 1978.) (Astrophysics and Space Science Library, Vol. 75.) Pp.xviii + 264. ISBN-90-277-0983-1. (Dordrecht, Boston, Mass. and London: D. Reidel Publishing company, 1979.) Dfl.65; $34.

Mathematics

ADIAN, S.I. The Burnside Problem and Identities in Groups. Translated from the Russian by John Lennox and James Wiegold. (Ergebnisse der Mathematik und ihrer Grenzgebiete/A Series of Modern Surveys in Mathemtics, Vol.95.) Pp.xi + 311. ISBN-3-540-08728-1. (Berlin and New York: Springer-Verlag, 1979.) DM 78; $42.90.

CANTRELL, James C. (ed.). Geometric topology. (Proceedings of the 1977 Georgia Topology Conference, held in Athens, Georgia, August 1-12, 1977.) Pp.xiii + 698. ISBN-0-12-158860-2. (New York and London: Academic Press, 1979.) $36.

CHOW, Yuan Shih, and TEICHER, Henry. Probability Theory: Independence, Interchangeability, Martingales. Pp.xv + 445. ISBN-3-540-90331-3. (Berlin and New York: Springer 1978.) DM 55; $30.30.

FRIED, ISAAC: Numerical solution of Differential Equations. (Computer Science and Applied Mathematics: a Series of Monographs and Textbooks.) Pp.xiii + 261. ISBN-0-12-267780-3. (New York and London: Academic Press, 1979.) $23.50.

GOODSTEIN, R.L. Fundamental Concepts of Mathematics. Second edition. (Pergamon International Library of Science, Technology, Engineering and Social Studies. International Series in Pure and Applied Mathematics, Vol. 107.) Pp.ix + 323. ISBN-0-08-021666-8. (Oxford and New York: Pergamon Press, 1979.) £7.

Psychology

VASTA, Ross. Studying Children: An Introduction to Research Methods. (A Series of Books in Psychology.) Pp.xi + 212. ISBN-0-7167-1067-6. (San Francisco: W. H. Freeman and Company, 1979.) Cloth $13; Paper $6.50.

WEISSTUB, David N. (edited by). Law and Psychiatry II: Proceedings of the Second International Symposium, held at the Clarke Institute of Psychiatry, Toronto, Canada, February 1978. Pp.xii + 163. ISBN-0-08-023901-3. (Oxford and New York: Pergamon Press, 1979.) £7.50.

WILLERMAN, Lee. The Psychology of Individual and Group Differences (A Series of Books in Psychology.) Pp.x + 531. ISBN-0-7167-0292-4. San Francisco; W. H. Freeman and Company, 1979.) $15.

Sociology

GARNICA, Olga K., and KING, Marhta L. (edited by). Language, Chilren and Society: The Effect of Social Factors on Children Learning to Communicate. Pp.xvii + 301. ISBN-0-08-023716-9. (Oxford and New York: Pergamon Press, 1979.) $20.

JULES-ROSETTE, Bennetta (edited by). The New Religions of Africa. (Modern Sociology: a Series of Monographs, Treatises and Texts.) Pp.xxii + 248. ISBN-0-89391-014-7. (Norwood, NJ: Ables Publishing Corporation, 1979.) $19.95.

KOCH, Frank. The New Corporate Philanthropy: How Society and Business Can Profit. Pp.x + 305. ISBN-0-306-40115-0. (New York and London: Plenum Press, 1979.) $18.50.

Louis, Karen Seashore, SIEBER, Sam Dixon. Bureaucracy and the Dispersed Organization: The Educational Extension Agent Experiment. (Modern Sociology: a Series of Monographs, Treatises and Texts.) Pp.xvi + 249. ISBN-0-89391-018-X. (Norwood, NJ: Ablex Publishing Corporation, 1979.) $19.95.

MAMAK, Alexander. Colour, Culture and Conflict: A Study of Pluralism in Fiji. Pp.xi + 203. ISBN-0-08-023354-6. (Oxford and New York: Pergamon Press, 1978.) £11.25.

SPRADLIN, W. W., and PORTERFIELD, P. B. Human Biosociology: From Cell to Culture. (Heidelberg Science Library.) Pp.xv + 227. ISBN-3-540-90350-X. (Berlin and New York: Springer-Verlag, 1979.) DM20; $11.

WEITZ, Shirley (edited by). Nonverbal Communication: Readings with Commentary. Second edition. Pp.x + 434. ISBN-0-19-502448-6. (Oxford and New York: Oxford University Press, 1979.) £6.75 net.

History of science

BLACK, Jr., George W. American Science and Technology: a Bicentennial Bibliography. Pp.xi + 170. ISBN-0-8093-0898-3. (Carbondale and Edwardsville: Southern Illinois University Press; London and Amsterdam: Feffer and Simons, Inc., 1979.) $12.95.

FORSCHEN UND NUTZEN: Wilhelm Ostwald zur Wissenschaftlichen Arbeit. Ans seinen Schriften ausgewählt, bearbeitet und zisammengestellt anlässlich seines 125 Geburtstages von Günther Lotz, Lothar Dunsch, Uta Kring. Mit enem Geleitwort von Peter Adolf Thiessen, und einer Einführung von Günther Lotz und Lothar Dunsch. (Beiträge zur Forschungs-technologie, Sonderband 1.) Pp. xlviii + 278. (Berlin: Akademie-Verlag, 1978.) DDR.38.

HORNBERGER, Theodore (edited with an Introduction and Notes by). A Goodly Gallerye: William Fulke's Book of Meteors (1563). (Memoirs of the American Philosophical Society, Vol. 130.) Pp.121. ISBN-0-87169-130-2. (Philadelphia, PA; The American Philosophical Society, 1979.) $6.

ANNOUNCING

Regulatory Peptides

A New International Journal from
ELSEVIER/NORTH-HOLLAND BIOMEDICAL PRESS

CALL FOR PAPERS

Chief Editors

Stephen R. Bloom,
Royal Postgraduate Medical School,
Hammersmith Hospital,
Ducane Road,
London W12 OHS,
U.K.

Floyd E. Bloom,
The Salk Institute,
P.O. Box 85800,
San Diego,
California 92138,
U.S.A.

REGULATORY PEPTIDES provides a medium for the prompt publication of interdisciplinary studies on the physiology and pathology of peptides of the gut, endocrine and nervous systems which regulate cell or tissue function. Papers emphasizing these objectives may be based on either fundamental or clinical observations obtained through the disciplines of morphology, cytochemistry, biochemistry, physiology, pathology, pharmacology or psychology. Four copies of each complete manuscript (including illustrations) should be submitted to either of the Chief Editors above. Only manuscripts which deal with original research not previously published and not under consideration for publication elsewhere will be considered. All papers accepted for review will be processed to an editorial decision to accept, revise or reject within one month of receipt in the editorial office. It is expected that all issues will be published within two months of receipt of the last paper of that issue. All manuscripts will be considered on an equivalent basis of scientific rigour and peer evaluation, in conjunction with an international editorial board. In no case should papers exceed 12 printed pages. (approximately 24 manuscript pages including figures).

REGULATORY PEPTIDES will be typeset and produced to the highest standards of the industry. Machine-coated paper, rendering faithful reproduction of halftones will also be utilised. Proof reading will be performed in the Publisher's Office and 50 free reprints of each paper will be provided to the author(s). Full Instructions to Authors will be available from the Publisher or from either Chief Editor.

Publication Schedule and Subscription Information:
1980, Volume 1 in 6 Issues (first issue scheduled for February 1980).
Subscription Price: US $80.50/Dfl.165.00 including postage.

CALL FOR PAPERS

To be published monthly from January 1980

Carcinogenesis

Aims and scope Carcinogenesis has been designed as a multidisciplinary journal bringing together all the varied aspects of research which would ultimately lead to the prevention of cancer in man. The journal will publish full papers and short communications which warrant prompt publication in the areas of carcinogenesis, mutagenesis; factors modifying these processes such as DNA repair, genetics and nutrition; metabolism of carcinogens; the mechanism of action of carcinogens and promoting agents; epidemiological studies; and the formation, detection, identification, and quantification of environmental carcinogens. Accepted manuscripts will be typeset, with high quality reproduction of photographs and illustrations, and the time from acceptance to publication will be no longer than 4 months and often less.

Instructions to Authors

Submission of Manuscripts

Detailed instructions are available from the publisher or either of the Executive Editors —

A. Dipple
Head, Molecular Aspects of
Chemical Carcinogenesis
Frederick Cancer Research Center

1980 VIth INTERNATIONAL HISTOCHEMISTRY AND CYTOCHEMISTRY CONGRESS VI

VITH INTERNATIONAL HISTOCHEMISTRY AND CYTOCHEMISTRY CONGRESS

17-22 AUGUST, 1980 BRIGHTON, ENGLAND

Symposia and topics will include: innovation and validation of methods for enzymes, tumour histochemistry, autoradiography, histochemistry in the electron microscope, mineralized tissues, nuclear histochemistry, analytical cytology, pharmacology and toxicology, histochemistry of nerve coordination, quantification, membranes, cell uptake and transport, immunocytochemistry, developmental processes, cell injury and death. Plus a range of other topics and free communications.

Closing date for abstracts 14 January 1980

Further information and abstract forms from:

SYMMETRY IN PHYSICS

J.P. ELLIOTT and P.G. DAWBER

Vol 1 Principles and Simple Applications
Vol 2 Further Applications

This is a comprehensive work with a very wide range of applications. The principles of symmetry are completely and carefully developed in the early chapters of vol. 1 so that no familiarity with any particular physical system is required. In each subsequent application the physical system is explained before beginning a study of the effects of symmetry.

Worked examples are used throughout the book to illustrate the arguments and each chapter is followed by a selection of problems and solutions.

Vol. 1 £12.50 0 333 26426 6
Vol. 2 £28.00 0 333 26427 4
2 Vol. set £35.00 0 333 11820 0

For further details please contact The Publicity Department, The Macmillan Press, 4 Little Essex Street, London WC2R 3LF.

M MACMILLAN PRESS

obituary

Michael Abercrombie

MR MICHAEL ABERCROMBIE FRS, Director of the Strangeways Research Laboratory, Cambridge, who was distinguished for his contributions to the study of cell locomotory behaviour and malignant invasion in tissue culture, died of cancer on 28 May 1979 after a protracted illness. The importance of his scientific achievement lies as much in his almost single-handed establishment of new general aproaches to the problems of development and malignancy as in the details of his own work. His good-humoured courtesy, fairness and deep humanity captured the devotion of all he met throughout the world.

Michael Abercrombie was born on 14 August 1912, at Rhyton Dymock, Gloucestershire. His father, Lascelles Abercrombie, was a distinguished poet and literary critic who later became the Goldsmith Reader at Oxford. In 1931 Michael Abercrombie obtained a Hastings scholarship to read zoology at Queen's College, Oxford. One of his tutors there was Gavin de Beer, an immensely erudite descriptive embryologist, who stimulated his interest in experimental embryology. He left Oxford in 1934 with a 1st in zoology and moved to the Strangeways Laboratory in Cambridge to work with C.H. Waddington who had a dazzling and fascinating influence on him. Here he experimented on the primitive streak in early blastoderms and, for this work, he obtained an Oxford BSc which was then a research degree.

Shortly before the war, he met M.L. Johnson (Jane) at Birmingham University and they were soon married. They spent the war years working together on the degeneration and regeneration of peripheral nerve, a programme of work supervised by J.Z. Young and chosen because of its possible usefulness to wartime surgery. This work was largely carried out in the Anatomy Department at Birmingham but the laboratory was not equipped and Michael had to surrender his superannuation in order to raise money for apparatus. I believe that at the same time he sold his wife's car; her sacrifice surpasses that of Faraday's wife whose linen gown was shredded into strips in order to insulate a coil!

After the war, he took up a lectureship in the Anatomy Department at University College London where J.Z. Young held the chair and here he became reader in charge of the Sub-department of Embryology and eventually, in 1959, a second chair was created for him within the department. Under his leadership, the sub-department soon became a major centre for embryology in Britain and out of it came the *Journal of Embryology and Experimental Morphology*. In 1962 he became Jodrell Professor of Zoology at University College and, in 1970, he succeeded Honor Fell as Director of the Strangeways Laboratory from which he was to retire in the autumn of 1979.

Michael Abercrombie was a founder member of the London Embryologists' Club which first met in November 1947 and which later became the British Society for Development Biology. He was also elected a Fellow of the Institut International d'Embryologie in 1956, a Fellow of the Royal Society in 1958 and was awarded an honorary doctorate by the University of Uppsala in Sweden in 1977.

The main theme of Abercrombie's research was a study of how signals which control locomotory behaviour are communicated between cells. He early noticed that the Schwann cells associated with regenerating peripheral nerve stumps in culture cease to move once the stumps have met and he soon performed the classic experiment of using time lapse cinematography to observe the behaviour of locomoting fibroblasts in a culture consisting of two confronted explants of chick heart tissue. In 1950 he was joined in this work by Joan Heaysman and they started the publication of their results in 1953.

These papers were of enormous importance to biology. They released a powerful new technique — the careful quantitative analysis of cell behaviour — and simultaneously revealed what has since proved to be probably the most important of the behavioural reactions, contact inhibition of locomotion. With Jack Ambrose, Abercrombie made a cytological study of contact inhibition in both normal and malignant cells and the resulting paper became the ninth most highly quoted in cancer in the period 1960-1975. It initiated an interest in the relation of the cell surface to malignancy which swept the cancer research world.

Until his retirement, he continued to work on models of malignant invasion in culture with Joan Heaysman and Pat Stephenson but, in the mid sixties, the emphasis of his research changed to the machinery of cell locomotion and Sue Pegrum, an electron microscopist, joined the group at University College. Later, when I moved with him to the Strangeways Laboratory, this subject became the main interest of our small research group. Among the topics more peripheral to the central theme, he continued his early primitive streak experiments with Ruth Bellairs, worked on liver regeneration with R.D. Harkness and investigated collagen formation during wound healing with D.W. James.

Michael Abercrombie's scientific ability was impressive. His command of techniques and comprehensive knowledge of the literature were matched only by his imaginative insight, his dogged pursuit of a problem and his high standard of objective evidence. His reluctance to speculate or to place too simple an interpretation on his results often made his papers hard going for the reader and sometimes led to the oversimplification or outright misrepresentation of his work by others.

In scientific discussion, as always, he was just and courteous. He spoke little (in his own opinion he was almost neurotically shy) and preferred to listen, but what he did say was very carefully thought out and well worth close study. He was extraordinarily knowledgeable not only within science (he read a minimum of 50 papers in preparation for each lecture to his students) but also in music, painting, literature and politics, rivalling, although he would never have agreed, the breadth of learning which he so admired in his friends Lancelot Hogben, J.B.S. Haldane and Gavin de Beer. Nevertheless, he remained totally modest and unassuming, never averse to humble tasks, even after attaining international distinction. He was patiently tolerant of shortcomings in others and was acutely sympathetic towards oppressed or unfortunate people, spending much of his time unobtrusively helping them.

These, then, were the qualities which have endeared Michael Abercrombie to so many. Perhaps his most extraordinary achievement is that, without exception, all who knew him well had a profound respect and fond regard for him. He overcame the hardships and endured the irony of his final illness with typical stoicism and good humour.

Graham A. Dunn

Julia Bell

JULIA BELL, FRCP died on 26 April 1979, shortly after her 100th birthday. She was one of the pioneers of human genetics and worked at University College London throughout her life.

Like many human geneticists she came into the subject from mathematics, which she had studied at Girton, and she worked as Karl Pearson's statistical assistant from

1908 to 1914. At about that time K.P. became increasingly aware of the lack of medical expertise in the Galton Laboratory, and it was at his suggestion that Julia Bell qualified as a doctor. Applied statistics and medicine formed the basis of the work for which she is famous, the collections of human pedigrees published under the general title of the *Treasury of Human Inheritance*. This was the first systematic attempt to document the distribution of human disease within families, and so anxious was Karl Pearson that these pedigrees should be most scrupulously recorded that in his 1912 preface he promised that the 'Treasury' would contain 'no reference to theoretical opinions.' In Julia Bell he found a fellow perfectionist with regard to the data, but by the 1920s a few mild opinions were obviously more acceptable. Subsequently Dr Bell wrote analytical articles which are among the classic papers of the subject. Perhaps the most notable are her 1940 paper on consanguinity rates and her 1937 paper with J.B.S. Haldane on the linkage between the genes for colour-blindness and haemophilia. This was the first demonstration 'that the principles of linkage which have been worked out for other animals also hold good for man.'

Dr Bell was on the staff of the Galton Laboratory until 1965 when she officially retired, at the age of 86! Although never Galton Professor of Human genetics herself she outlived the first three, Pearson, Fisher and Penrose, and in her 90s was still sufficiently concerned with the Laboratory to remonstrate with the Galton Professor when she felt it to be necessary! She was a supporter of the Women's Suffrage Movement, but never a militant. She was something rarer, one of the first generation of women to engage in professional scientific research, and to do it supremely well.

Elizabeth B. Robson

N.D. Riley

NORMAN DENBIGH RILEY, CBE, who died on 26 May 1979 at the age of 88 was an eminent British entomologist with a high reputation as a lepidopterist and as a tireless and effective worker in the interests of international entomology.

For nearly a quarter of a century he was head (Keeper) of the Department of Entomology in the British Museum (Natural History), and between the 1930s and 1950s saw it transformed from a dusty insect storehouse into a modern research institution. We may claim for him, as such a modest man would never claim for himself, that he was largely responsible for the high regard in which the Department of Entomology is still undoubtedly held internationally.

Fifty years ago service to one's country was more esteemed than it is today, and in 1932 when E.E. Austen (a military man himself) retired as Keeper of Entomology he was instrumental in securing Riley's appointment as his successor in preference to F.W. Edwards. Riley had served in the army with distinction for the whole length of the Great War, rising to the rank of Captain, whereas Edwards — the scientifically more qualified man — had been a non-combatant pacifist through his Quaker convictions.

While Riley might have been fortunate at this juncture in his life, his promotion to Keeper was to prove amply justified. He had a taste for administration unusual in entomologists and soon became the architect both figuratively and almost literally (as he did much to plan the present departmental building) of an expanding Department of Entomology. During his Keepership the insect collections grew enormously, often through purchase of specialized collections negotiated by Riley and there were comparable increases in the department staff. Riley himself was a gregarious man, and when his staff became large enough he encouraged more contact amongst them by organizing annual staff dinner dances, which proved a popular innovation in an otherwise rather stuffy museum. During the Second World War he organised the evacuation of large parts of the collection and the library to safe quarters, and their return after the war, although he remained in South Kensington. The CBE was conferred on Riley in 1952.

In his Presidential Address to the Royal Entomological Society, Riley amused his audience by recalling when his small daughter was overhead to say "My daddy doesn't work — he goes to the Museum." In this she had caught Riley's character to a nicety, for to him work and pleasure were synonymous, and long after his official retirement in 1955, until his death in fact, he was a regular visitor to his beloved collection of butterflies in the Museum.

Butterflies were Riley's life-long scientific interest, and one that he was able to indulge professionally from the time of his appointment to the Museum staff as an Assistant in 1911 (which followed on the heels of a short period learning entomology while a demonstrator at the nearby Imperial College). It was not until his return from the war in 1919, however, that Riley published his first modest paper, describing some new Brazilian species of butterflies, but from then on he published regularly for over half a century, his bibliography of about 400 works including books, editorials and reviews as well as scientific papers. His scientific contributions to lepidopterology will be assessed in specialist journals, but mention should be made of his book written in collaboration with his friend Lionel Higgins entitled *A Field Guide to the Butterflies of Britain and Europe*: although only published in 1970 this has already run through several editions and has been issued in nine languages.

Riley lived as a boy in South London, where he was born in the suburb of Tooting on 20 September 1890 and where he was educated at Harlington School, Balham and Dulwich College. A neighbour was Richard South, doyen amongst British Lepidopterists, and it was he who stimulated Riley's childhood interest in butterflies — so effectively as it turned out that Riley even on the eve of his death was discussing butterfly nomenclature with a friend.

Butterflies in spite of, or perhaps because of, their popularity have always had their problems with scientific names, and Riley was inexorably drawn into the intricacies of nomenclature, with the result that he served for 15 years (from 1950 to 1965) on the International Commission for Zoological Nomenclature. As commision Secretary and member of its editorial Committee he was the mastermind behind the current edition of the International Code of Zoological Nomenclature and bore much of the burden of its production.

He was prominent also in international biology through his election to the International Entomological Congresses and his long connection with Congress organization. For a time Riley served as Chairman of the Entomological Section of the International Union of Biological Sciences. Responsibilities of this kind involved him in occasional distant travel, but most of his collecting was done in Europe. At home Riley's energies were poured into Society affairs. He was a Fellow of the Royal Entomological Society for 67 years (elected in 1912). For the last twenty of these, until his death he held the rare distinction of a Life Fellowship. Riley served on the Society's council (1921-23, 1929-30), and as its Secretary (1926-29, 1941-51), Treasurer (1939-40) and President (1951-52).

He belonged to the British Entomological and Natural History Society for an even longer period, having joined as a boy in 1902, and was its President in 1923-24. This Society gave him special links with many amateur specialists who were keen readers of *The Entomologist* a monthly journal largely devoted to Lepidoptera that Riley owned and edited for thirty-six years (1923-1959). A position he relished was that of organizer over many years of the Verrall Supper, an annual gathering of professional and amateur entomologists; in a long life he missed only two of these occasions and was present at the very first in 1912.

Norman Riley enjoyed every moment of a hard-working life and was the perfect examplar of those qualities that in a more gentlemanly age were laid down for the conduct of British Museum staff — that they should be "persons of honour, integrity and liberality." He is survived by his widow, a son and daughter.

Pamela Gilbert

Georgiana M. Bonser

DR GEORGINA M. BONSER (née Duthie), MD (Manchester), FRCP (London), a leading woman doctor engaged in cancer research in England, died on 9 June 1979 at the age of 81.

She was born on 5 May 1898 and studied medicine in Manchester University and at King's College Hospital, London, qualifying in 1920. By 1923, she had been awarded her MD with distinction and won a travelling fellowship which enabled her to spend a year at the Institut Pasteur in Paris. While there, she met her future husband, Kenneth Bonser, an architect. In 1927 she began her long association with Leeds University and its hospitals. Fortuitously, her interests were channelled into cancer research by her chief, Professor Matthew Stewart. She was a woman with a strong sense of purpose who saw two challenges in her life, the problems of cancer and the need for women in the medical profession to establish their rightful place in an essentially male preserve. Dr Bonser's efforts were eventually to be recognised by her election to the chairmanship of the Leeds branch of the British Medical Association, in 1953, and presidency of the Medical Women's Federation in 1959, which speak for her tenacity and political acumen.

But to appreciate her real achievement, it must be recalled that cancer research, when she began, paid the handsome salary of £200 a year and it was necessary for her to take a part-time job in pathology in order to have enough money to live on. She held several posts in the Leeds hospitals and university until she finally became reader in experimental pathology and cancer research and a consultant pathologist at St. James's Hospital and lived to see this hospital translated from a poor law institution to a modern teaching hospital.

Dr Bonser's contribution to knowledge has been in the studies of chemically induced carcinogenesis of the bladder. Although the association of bladder cancer and the dyeing industry had been established in the late nineteenth century, all efforts to induce bladder tumours with the products from the dyeworks or urine of workers affected with bladder cancer were a failure. Dr Bonser, in 1937, reviewed these disappointing results which were somewhat reminiscent of the research for some of the more elusive infective agents some 50 years previously. Hueper's report that the feeding of large doses of ß-naphthylamine to dogs produced bladder cancer was the turning point. By 1943, Dr Bonser reported that the following feeding purified ß-naphthylamine to dogs for 5 years, bladder cancer could be induced. This helped to remove suspicion from α-naphthylamine and identify one hazard in the dyeing industry.

She soon realised that the dog was too cumbersome and expensive an animal for research and concentrated on developing models in small animals. From this time, progress was much more rapid as the waiting time to see the result of an experiment was then a matter of one to two years. Dr Bonser's team confirmed that 2-acetylaminofluorene when fed to mice was a bladder carcinogen; this was the first in a long series of experiments that resulted in her being an expert on the interpretation of the pathology of the bladder in laboratory animals.

It became clear to Dr Bonser that she needed specialist help; in part it came from Professor L.N. Pyrah, a urological surgeon who helped with surgical techniques in the animals but the whole programme really became most effective when she recruited D.B. Clayson, a young chemist and J.W. Jull, a biologist to help her. There then followed a long haul in which the metabolism of several potential bladder carcinogens was studied and the carcinogenic properties of their various derivatives tested in her systems. An important part of the techniques developed by Dr Bonser's team was the direct implantation of carcinogens in a variety of different vehicles into the bladders of rats and mice. The net result of their efforts over the next 15 years was to put one part of the bladder carcinogenesis story on to a sound scientific basis. Its eventual impact reached far beyond the dyeworks to embrace the workers in rubber and cable making industries who came into contact with ß-naphthylamine. Dr Bonser's strength lay in a sense of purpose, her strong discipline and sound knowledge of general pathology as well as her natural clinical practice; in 1961 she was co-author of a book on the pathology of breast cancer.

In the University her research was solidly based on her nose for a good experiment and skill at being able to interprete the results. Many others who have delved in this field had been hopelessly wrong as they could not tell the difference between hyperplasia of the bladder mucosa from that of early carcinoma. One of her last tasks after her retirement was the writing with one of her former pupils, of a chapter on the pathology of the bladder in experimental animals in the handbook produced by the International Agency for Cancer Research.

Today, with the flood gates open to pour money into testing for carcinogens, it is salutary to reflect that in the smoke and grime of pre-war Leeds, this small, determined and formidable woman was quietly laying the corner stones of the work. The combination of her keen mind and dogged persistence was rewarded by achieving a few lasting goals, but what is most important, she was one of those pioneering women scientists ahead of her time. Georgiana Bonser had been a great credit to her University and dealt a nasty jolt to male chauvinism in medicine, both of which must have given her the satisfaction of a life well spent.

Edward H. Cooper

Sir Peter Venables

SIR PETER VENABLES died at his home in Birmingham on Sunday 17 June 1979. He was 74. His passing leaves a gap in the world of education in Britain that cannot easily be filled.

Peter Venables started his career as a chemist; to use his own words as "a mere chemist." He emerged from Liverpool University in 1925 with a first-class honours degree in chemistry. It was typical of the man, and of his later career, that, despite the quality of his first degree, he should, before embarking on study for a PhD, have spent a year acquiring an Education Diploma. He then spent four years in research, obtaining a PhD in 1928 followed by 2 years of postdoctoral work.

For the next 11 years his career followed the standard pattern of a teacher in higher education. First as a Lecturer and later as a Senior Lecturer in the Leicester College of Technology (now the Leicester Polytechnic) and then as Head of the Science Department at the South-East Essex Technical College he continued to teach and to carry out research in chemistry. But while at Leicester his lifelong interest in the visual arts was stimulated by the close contacts he made with the staff of the College of Art.

But it was in 1941, at the age of 37, that he took the critical step that was to determine the path of his future career. He accepted the post of Principal of the Municipal College at Southend-on-Sea. This was a move into academic administration. From now on Peter Venables was not "a mere chemist"; he had entered the curious world where education and administration are blended. Academic excellence is a necessary passport to enter this world but in it academic work must take second place (and often third or fourth place), yielding to the need to provide leadership to a company of men and women characterised by independence of mind and often of equal independence of action. He had the qualities required for success, an absolute integrity of purpose which he would pursue, as the occasion required, with consummate patience, with a formidable show of strength or even, where necessary, with guile. He had a mischievous wit and could school his countenance to betray no expression whatsoever as he uttered his most outrageous quips. All in all he inspired in his friends and colleagues both an absolute trust and a deep affection, a combination that inevitably makes a leader of men, and a leader he was to be for the rest of his career.

From Southend-on-Sea he moved in 1947 to become principal of the Royal Technical College at Salford. During the next nine years he laid there the foundation upon which, much later, that college was to become the University of Salford. His qualities were recognised more widely by his election as President and later Chairman of the Council of the Association of Principals of Technical Institutions.

In 1956 he moved again, this time to the College of Technology in Birmingham. Here for a decade he presided over its development as the first College of Advanced Technology in the country, of its transition from a CAT to a technological university and, for a further three years as the first Vice-Chancellor of the University of Aston. He was, therefore, deeply involved in the pedagogical and political arguments about the growth of university and technological education throughout a period of almost revolutionary change. He brought to them his wisdom, his vision and his devotion to a humanitarian ideal. His recognition of the need to draw together the interests of industry and education led him to pioneer the sandwich course which found an honourable place in the spectrum of educational provision.

He also found time and energy to give unstinting service as Chairman, President or member of a whole range of other educational institutions. Of particular note, perhaps was the fact that the British Broadcasting Corporation and the Independent Television Authority, if they agreed on nothing else, both chose him to act over the same period as Chairman of their Further Education Advisory Council and Adult Education Advisory Committee respectively — surely a unique distinction in educational broadcasting.

In 1968 he was also Vice-Chairman of the Committee of Vice-Chancellors and Principals and it was while he held this post that he accepted an invitation from Jennie Lee to become Chairman of the Planning Committee of the Open University. It was an inspired choice; but it came as a surprise and a shock to many of his colleagues who did not share his faith in this new educational venture. But it was a venture that called for all the qualities that he had in abundance, humanitarianism, egalitarianism, the desire to harness technology to the service of society. He imprinted these qualities upon the new institution not only during the planning phase but also, as its first Pro-Chancellor and Chairman of Council, during its early formative years. Throughout that period and, indeed, right up to his death, he remained the consultant architect; his was the grand design even though others might build particular bits.

Numerous honours came his way but he remained just the same, a straightforward and uncomplicated chap. For 47 years he was sustained by a very happy and stable home. His wife, Ethel, a distinguished scholar in her own right, shared his hopes and his motives. Our sympathy goes to her and to the children in their sad loss, a loss that seems as personal to many of us as it must be to them.

Walter Perry

H.B.D. Kettlewell

HENRY BERNARD DAVIS KETTLEWELL died on 10 May 1979, aged 72. He was one of those dedicated scientists who gave up work as a medical practitioner in order to conduct biological research, so that his professional life falls into two parts.

He was the son of Henry Kettlewell and Kate Davis. In 1936 he married Hazel Margaret, daughter of Sir Frank Wiltshire, having one son and one daughter.

He was educated at Charterhouse and Caius College, Cambridge. He obtained the degrees of MA, MB, and B Chir, and acquiring the status of MRCS and LRCP, he held several hospital appointments. During the war of 1939-45 he worked at the Woking War Hospital, subsequently taking up general practice at Cranleigh, Surrey.

In 1949 he emigrated to South Africa, researching for a time on locust control. He also conducted expeditions to the Kalahari, Belgian Congo and Mozambique. Characteristically, he drove his motor car from Cape Town to Alexandria when in 1952 he decided to take up a Nuffield Research Fellowship in genetics in the Department of Zoology at Oxford. Two years later he became a Senior Research Officer, a position he held until his retirement in 1974. He was elected a Fellow of Wolfson College, Oxford and obtained the degree of DSc at Oxford in 1975.

During his research career, he undertook lecture tours in the USA and Canada and visited Brazil for *Life Magazine* on the occasion of the centenary of the *Origin of Species*. He was co-founder of the Rothschild-Cockayne-Kettlewell Collection of Lepidoptera now housed in the Natural History Museum, South Kensington. This is of a unique type, illustrating the genetics of butterflies and moths with full references to the literature accompanying each set of specimens.

Bernard Kettlewell was the finest living ecologist of the Lepidoptera. Moreover, he was blessed with the good luck which ought to attend devoted field workers. On one occasion he found himself surrounded by large numbers of the Bath White butterfly *Pontia daplidice* in South Cornwall and had a specimen of this and of another fabulously rare species the Short tailed Blue *Everes argiades*, in his net at the same time.

It is, in particular, with the study of industrial melanism in the Lepidoptera that Kettlewell's name will always be associated. That phenomenon involves the most spectacular, though not the most profound, evolutionary change which has ever been witnessed. He showed that over a hundred species are affected by it in Britain alone. The correct interpretation of the subject had been handicapped by the mistakes and failures of others in the past. These included the wholly incorrect explanation, depending on mutation-pressure, put forward by Heslop-Harrison. Moreover, both ornithologists and entomologists had entirely failed to realise that birds hunting by sight may selectively destroy resting moths. It was the triumph of Kettlewell to show by much detailed observation and experiment that the explanation of this occurrence by mutation-pressure is invalid, and to confute those who maintained it by collaborating with N. Tinbergen to produce brilliant cinematograph pictures demonstrating such predation.

Kettlewell was able to analyse the whole subject of industrial melanism with great success, using in particular the Peppered Moth, *Biston betularia*, of which he bred thousands of specimens for study in the field. Moreover, by various recapture methods he obtained definite information on their survival. Such melanism is confined to species that rest exposed, matching their background. Kettlewell demonstrated that the black form survives better in polluted areas but is eliminated in normal countryside. He also studied the genetics of the situation and showed that the melanism is controlled as a polymorphism, with heterozygous advantage.

This work has important ancillary applications, including an impressive demonstration of the evolution of dominance obtained by crossing the British Peppered Moth with a related Canadian species. Also the evolution of a super-gene in the Oak Eggar, *Lasiocampa quercus*. His work on the Lepidoptera extended in many other directions, including the detection of speciation in its early stages due to isolation by distance. He also carried out a remarkable analysis of variation in the Scarlet Tiger Moth, *Panaxia dominula*, conducted partly in the garden of his country house between Oxford and Banbury.

He recorded his research results in many articles. He also wrote several books, the most important being *The Evolution of Melanism*, 1973 (Clarendon Press, Oxford).

His work gained considerable recognition. He was awarded the Darwin Medal of the USSR in 1959, and the Mendel Medal in Czechoslovakia in 1965. Throughout his research career Kettlewell was constantly demonstrating the importance of studying evolution by observation and experiment using the techniques of ecological genetics.

ICE AGES

Solving the Mystery

Professor John Imbrie and
Katherine Palmer Imbrie

May 1979 £6.95 224pp 0 333 26767 2 illustrated

Knowledge that the world once endured an ice age has been widespread for more than a century. Indeed, the concept is now so familiar that nearly every winter storm prompts dramatic headlines: Is a new ice age upon us?

This book tackles that burning question and attempts to unfold, for the interested general reader and those with a more academic interest, the entire saga of the Ice Age 'mystery' – why ice ages occurred, what they were like, and when the next one is due.

It is written by one of the principal scientists on the multi-million dollar CLIMAP project which set out to study changes in the climate of the earth over the past 700,000 years. Out of the group's analytical work came an exciting by-product: confirmation of the correctness of one of the several theories of what causes ice ages to occur. The theory that was confirmed, and is now explained along with many others in ICE AGES, is the Milankovitch, or astronomical theory which sees periodical glaciation as the result of three regular movements the earth makes as it travels around the sun: changing ellipticity of the earth's orbit, "wobble" of the earth's axis, and the changing tilt of the earth's axis.

"ICE AGES is fascinating in its scientific interest and also as a detective story. I recommend it to all." Dr. William F. Libby, Nobel Laureate.

APPOINTMENTS VACANT

PRE AND POSTDOCTORAL POSITIONS

are available for individuals with microbiology background for studies on the protein synthesising system with special emphasis on ribosomes — topography, biogenesis and function. Teaching opportunities are available. Reply with résumé to: Dr Bruce H. Sells, Professor and Director, Laboratories of Molecular Biology, Faculty of Medicine, Health Sciences Centre, Memorial University of Newfoundland, St John's, Newfoundland A1B 3V6, Canada. W350(A)

THE UNIVERSITY OF PAPUA NEW GUINEA

(Port Moresby)

Applications are invited for the post of

PROFESSOR OF HUMAN BIOLOGY

within the
FACULTY OF MEDICINE.

Applicants should have a distinguished academic record with either Gross Anatomy, Histology, Biochemistry or Physiology as their field of interest. A medical qualification would be a distinct advantage, although a person who is not medically qualified may apply. Teaching and/or research experience in a developing country would also be an advantage. The appointee will provide academic leadership, participate in undergraduate and graduate teaching in the basic medical sciences, and stimulate research. He/she will also encourage the development of Papua New Guinea national academic staff. The Professor will not necessarily have any administrative responsibilities although he/she can be elected to positions carrying such responsibilities. The Department of Human Biology is responsible for teaching the basic medical sciences to undergraduate and postgraduate students. Courses offered include Gross Anatomy, Histology, Embryology and Neuroanatomy; Biochemistry, Nutrition and Genetics; Physiology and Neurophysiology, and Pharmacology.

Salary: K18,675 pa (£1 Sterling = K1.57) pa. (In addition a clinical allowance of K2,000 pa will be payable). Family passages; baggage allowance; 3 years contract; 24% gratuity of salary of which 5% is taxable; support for approved research; rent-free accommodation; annual leave; generous education allowances; medical assurance scheme.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to the Secretary, Box 4820, University PO., Papua New Guinea by 8 November, 1979. Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 1DT. Further details may be obtained from either address. 3203(A)

TECHNICIAN or JUNIOR TECHNICIAN required by the Institute of Cancer Research in association with the Royal Marsden Hospital at Sutton, Surrey. Candidates should have an interest in cell culture and, ideally, some previous experience in this field and also in enzymology. The individual appointed will take part in a new MRC Project on clinical and laboratory aspects of head and neck cancer, commencing September — October, 1979. Salary in scale £3,261 to £3,813 p.a. (Technician) or £2,169 to £3,015 p.a. (Junior Technician), plus London Allowance of £354 p.a. (scales under review). Salary will depend on age and qualifications, two 'A' levels in science subjects for Junior Technician and either a Degree, HNC or equivalent qualification for a Technician appointment. Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London, SW7 3NU, quoting ref. 301/B/73. Closing date for applications, 28th September, 1979. 3149(A)

MEDICAL RESEARCH COUNCIL OF NEW ZEALAND

DIRECTOR

VIRUS RESEARCH UNIT

Applications are invited from medically and non-medically qualified virologists with proven experience in research for the position of Director of the Council's Virus Research Unit which is located in the Microbiology Department of the University of Otago, Dunedin, New Zealand. Applications from clinicians and research workers interested in developing a programme in association with hospital-based diagnostic virology would also be entertained.

The salary will be based on qualifications and experience but will be equivalent to that of Associate Professor in the University. In the case of an exceptionally well-qualified applicant Council will consider an appointment at a level equivalent to that of Professor.

Salary: Associate Professor (medical) NZ$27,365-30,860; Associate Professor (non-medical) NZ$21,565; Professor (medical) NZ$30,365-33,865; Professor (non-medical) NZ$23,865-29,865.

It should also be noted that wage orders increasing these salaries by approximately 15% are expected to be applied in the near future.

Further particulars are available from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF; from the Registrar of the University of Otago, PO Box 56, Dunedin, New Zealand, or direct from J.A. Borrows, Technical Secretary, P.O. Box 6063, Dunedin, New Zealand.

Applications close in New Zealand and London on 1 December, 1979.

3177(A)

DEPARTMENT OF BIOPHYSICS

KING'S COLLEGE

London

and

NATIONAL INSTITUTE FOR MEDICAL RESEARCH

Applications are invited for a postdoctoral position, tenable for one year in the first instance, with the possibility of renewal for three years, supported by W.H.O. The research concerns the mechanism by which the malaria parasite enters the host red cell. Experience in biochemical or biophysical aspects of membrane and cytoskeleton research would be an advantage; prior knowledge of parasitology is not essential.

Applications with curriculum vitae and names of two referees to D.M. Drummie, Administrative Assistant, Department of Biophysics, King's College, 26-29 Drury Lane, London WC2. 3163(A)

EAST MALLING RESEARCH STATION

LIBRARIAN

Librarian to take responsibility for library and associated services at major horticultural research station conducting a wide range of fundamental and applied studies on problems of commercial fruit growing.

Candidates must have degree in biology, horticulture or agriculture with postgraduate librarianship or information science qualification with at least 5 years professional experience.

'On-line' (Lockheed) experience an advantage.

Salary in the scale £5,520 to £6,519 (£5,950 to £7,250 from 1st January 1980); non-contributory pension scheme.

Application form and further details from Secretary, East Malling Research Station, Maidstone, Kent. 3146(A)

BBC OPEN UNIVERSITY PRODUCTION CENTRE

Vacancies exist for production staff at the Production Assistant level.

Candidates must have a good Honours degree in one of the following: Geology, Biochemistry, Mathematics, Psychology (or another Social Sciences subject). At least two years post-university experience and the ability to work on a wide range of subject disciplines is essential.

Successful applicants, who will be given production training if necessary, will work on all aspects of the production of radio and television programmes for the Open University.

Open University Production Centre is based at Alexandra Palace but will move to Milton Keynes in 1981.

Salary: £6,385 to £8,405 p.a. Plus unconsolidated allowance £617 p.a. Relocation expenses considered.

Telephone or write immediately for an application form, enclosing addressed envelope and quotiong reference 2527/N to: *Appointments Department, BBC, London W1A 1AA. Telephone 01-580 4468 Ext. 4619.*

BBC tv

A.R.C. ANIMAL BREEDING RESEARCH ORGANISATION

IMMUNOGENETICISTS

SENIOR SCIENTIFIC OFFICER/SCIENTIFIC OFFICER

Applications are invited for two posts:

Project: To study histocompatibility antigens in tropical cattle and their possible association with disease resistance. Part of the project, involving Theileriosis, will be in collaboration with the Centre for Tropical Veterinary Medicine (Edinburgh).

Duration: Three years.

Location: The posts will be based in the Department of Immunology, ABRO, Edinburgh, where the appointees are expected to spend one year, with the remaining two years in Africa.

Qualifications: (1) SENIOR SCIENTIFIC OFFICER (Project Leader):
1st or Upper 2nd Class Honours in a biological science, with at least 4 years relevant post-graduate experience preferably including immunology or genetics.
(2) SCIENTIFIC OFFICER
A degree or HND in a biological science with, preferably, immunological or genetical experience.

Salary: (1) SSO: within scale £6,332 to £8,705
(from 1.1.80) (2) SO: within scale £3,591 to £5,486

Starting salary according to qualifications and experience.

Each post will attract tax free overseas allowances and terms similar to those for Ministry of Overseas Development Technical Assistance appointments and is superannuated in a non-contributory scheme.

Applications: Full curriculum vitae with names of two referees to the Secretary, ARC Animal Breeding Research Organisation, West Mains Road, Edinburgh EH9 3JQ, by 13th October, 1979 from whom further particulars are available.

3161(A)

UNIVERSITY OF DUBLIN
Trinity College

LECTURESHIPS IN PHARMACOLOGY
(2 posts)

Applications are invited for two Lectureships in the Department of Pharmacology, Trinity College, Dublin, which are available immediately.

In the case of the first position, preference may be given to medically qualified applicants; for the second position, preference will be given to candidates with qualifications and experience in Pharmacology, Pharmacy or a related area.

Salary scale: £5,078 to £10,038 p.a.

Appointment will be made at a point appropriate to the qualifications and experience of the successful candidates; in the case of the first position above, appointment may be made within the full range of the Lecturer scale; in the case of the second post, appointment is likely to be made within the range £5,078 to £6,462 p.a. There is a non-contributory pension scheme.

Application forms and further particulars relating to these posts may be obtained from:

The Establishment Officer
West Theatre
Trinity College
Dublin 2

who will receive completed applications **up to Friday, 28th September, 1979.** 3192(A)

UNIVERSITY OF OXFORD
in ASSOCIATION with ST. HUGH'S COLLEGE
LECTURERSHIP IN ASTRONOMY

Applications are invited, from men and women candidates, for a University Lecturership in Astronomy, in the Department of Astrophysics, to be filled from 1 January 1980 or as soon as possible thereafter.

Preference will be given to applicants with a broad knowledge of astrophysics whose research interests lie in the field of optical astronomy (including the ultraviolet and infrared regions).

The stipend will be according to age on the scale £4,232 to £9,000 (under review) with superannuation.

The lecturership may be held with a tutorial fellowship in physics at St. Hugh's College and a linked lecturership at St. Edmund Hall. Applicants should state whether they wish to be considered for the college posts.

Further details of the university and college posts may be obtained from Professor D.E. Blackwell, Department of Astrophysics, South Parks Road, Oxford, OX1 3RQ, to whom applications (one typed copy) should be sent before 15 October, 1979. Applications should contain a statement of qualifications, a list of publications, an outline of a proposed research programme and the names of three referees. 3155(A)

GREEK BIOCHEMISTS
MOLECULAR BIOLOGISTS

The Laboratory of Biological Chemistry, University of Ioannina Medical School, invites applications for two positions of

ΕΠΙΜΕΛΗΤΑΙ

starting December 1st, 1979 or later. Applicants must be fluent in Greek, and have a PhD in biochemistry/molecular biology, or an MD with strong interests and experience in the above subjects.

The successful candidates will be expected to take part in the teaching program for about 100 medical students and in the research interests of the laboratory. These interests currently are in enzymology, protein chemistry, and membranes. In addition, a Center for Brucellosis, an endemic disease in the area, is under consideration. The basic salary is about 19,000 Drs per month before taxes and is expected to be supplemented from other sources.

Applicants should forward their curriculum vitae with bibliography, two or more letters of recommendation, and a brief outline of research interests to: Orestes Tsolas, PhD, Professor, Laboratory of Biological Chemistry, University of Ioannina Medical School, Ioannina, Greece. (Telephone 0651-33442). W351(A)

THE UNIVERSITY OF MANCHESTER. Research Technician (grade 5) required to work in the Department of Anatomy. Applications are invited for the post of research technician to work in the area of experimental neurology. Applicants must hold HNC or equivalent and have at least 8 years' laboratory experience. Competence in a wide range of modern techniques in histology and microscopy including autoradiography is essential. Previous experience in research work is required and a working knowledge of the use of neuroanatomical, neurophysiological or neuropharmacological research techniques would be a considerable advantage. Salary on the interim scale £3,700 to £4,320 p.a. together with further comparability payments and subject to overall review as from 1st October 1979. Applications giving details of age, qualifications, experience and the names of two referees should be sent to Professor P.F. Harris, Department of Anatomy, Medical School, University of Manchester, Manchester M13 9PT, by 30th September 1979. 3109(A)

LINCOLN COLLEGE
New Zealand
LECTURER IN ANIMAL NUTRITION

The Council of Lincoln College, University College of Agriculture, invites applications for appointment to the position of Lecturer in Animal Nutrition. Applicants must hold a degree in Agricultural Science, Veterinary Science or some related branch of science, with a higher degree in animal nutrition. Preference will be given to those candidates with experience of research in the physiology of digestion and/or control of feed intake in ruminants. The appointee will be attached to the Animal Science department within the Animal Sciences Group.

The salary scale for lecturers ranges from NZ$11,894 to NZ$14,615. It is expected that the recent Ruling Rate Survey increase of 10.4% and General Wage Order of 4.5% will be applied.

Travel and removal expenses will be reimbursed up to specified limits. New Zealand Government Superannuation will be available.

Conditions of Appointment giving further details of this position can be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the College.

Applications close on 31 October, 1979. 3167(A)

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL
(University of London)
SCHOOL OF PATHOLOGY
POST-DOCTORAL BIOCHEMIST RESEARCH ASSISTANT

Applications are invited from post-doctoral biochemists to collaborate in a 3-year project, supported by NCI (USA) funds, to study carcinogenesis *in vitro* in human bladder explants.

Applicants should have worked in the field of carcinogen metabolism and have appropriate experience in techniques for studying the adducts formed between carcinogens and DNA or proteins. Technical assistance will be available.

The appointment is for one year in the first instance, renewable for a further two years. Starting salary on the scale effective 1 October 1979 within the range £4,835 to £6,858 inclusive of London allowance according to age, qualifications and experience.

Please send applications, with curriculum vitae and the names and addresses of two referees to Dr R.M. Hicks, School of Pathology, The Middlesex Hospital Medical School, London W1P 7LD by 1 October 1979. 3144(A)

THE UNIVERSITY OF MANCHESTER
BARKER CHAIR OF CRYPTOGAMIC BOTANY

Applications are invited for the Barker Chair of Cryptogamic Botany which will fall vacant on October 1st, 1980 following the retirement of Professor John Colhoun. The University has a preference for candidates with interests in the applied fields. The other Chair in Botany is the George Harrison Chair to which Dr Elizabeth G Cutter has been elected. Particulars of the appointment may be obtained from the Registrar.

Applications (2 copies, 1 suitable for photocopying), giving full details of qualifications, experience, research etc., and the names and addresses of three persons to whom reference may be made, should be sent to The Registrar, The University, Manchester, M13 9PL by October 10th. 3159(A)

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL
(University of London)
SCHOOL OF PATHOLOGY
MEDICAL LABORATORY SCIENTIFIC OFFICER BIOCHEMIST
(Whitley Council)

Applications are invited from Scientific Officers to assist in a research project involving carcinogenesis *in vitro* in human tissues. Candidates should be associates of the IST, IMLT or equivalent and must have had experience in a biochemical laboratory preferably working on the metabolism of carcinogens.

The appointment is funded by the NCI (USA) and is for one year initially, renewable for a further two. Salary in the range £4,050 to £5,034 depending on age, qualifications and experience.

Please send applications, with curriculum vitae and the names and addresses of two referees to Dr R.M. Hicks, School of Pathology, The Middlesex Hospital Medical School, London, W1P 7LD, by 1 October 1979. 3145(A)

FU BERLIN

INSTITUT FÜR KRISTALLOGRAPHIE

Applications are invited for a

POSTDOCTORAL RESEARCH POSITION IN STRUCTURAL STUDIES ON BIOPOLYMERS

tenable for one/two years with possible prolongation. Salary in scale 40000 to 60000 DM depending on age and experience.

The successful candidate is expected to have sound experience in biochemistry/molecular biology. Background in structural studies using X-ray diffraction and other physical methods is desirable. Work will focus to structure of nucleic acids and/or bacterial cell walls.

Please send applications with curriculum vitae, qualifications and names of two referees to Prof. Dr. Bradaczek, Institut für Kristallographie, Freie Universität Berlin, Takustraße 6, D-1000 Berlin 33. W349(A)

GUY'S HOSPITAL MEDICAL SCHOOL

Unit for Metabolic Medicine

DEPARTMENT OF MEDICINE

GRADUATE OR POSTDOCTORAL RESEARCH ASSISTANT

(Biochemist or Pharmacologist)

required for two years in the Unit for Metabolic Medicine to work on a research project concerned with insulin metabolism and metabolic control in diabetes mellitus.

Salary according to qualifications and experience, with London Allowance.

Apply in writing, with full curriculum vitae, to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. MM1. 3180(A)

THE ROWETT RESEARCH INSTITUTE

Bucksburn, Aberdeen, AB2 9SB

PATHOLOGIST/CELL BIOLOGIST

Scientific Officer/Higher Scientific Officer Grade

Applications are invited for a post in the Institute's Department of Experimental Pathology, which studies the pathology of nutritional disease in farm animals, and diseases associated with specific husbandry practices.

The post is for a morphologist who has a particular interest in cytochemical and ultrastructural methods and their application to the study of growth, and nutritional and idiopathic neuromuscular diseases in farm animals.

Candidates should possess a 1st or upper 2nd class Honours degree in the biological sciences. At least two years relevant postgraduate research experience is required for HSO grading.

Salary Scales: Scientific Officer £3,289 to £5,085 p.a. or Higher Scientific Officer £4,727 to £6,211 p.a. with placing according to qualifications and experience. On 1 January 1980 these scales will be increased to: S.O. £3,591 to £5,486 p.a. and H.S.O. £5,097 to £6,737.

There is a non-contributory Superannuation scheme.

Further details of the post may be obtained from the Secretary of the Institute, to whom applications should be submitted by 5 October 1979 together with the names of two people to whom reference can be made. 3204(A)

UNIVERSITY OF LONDON

INSTITUTE OF NEUROLOGY

RESEARCH ASSISTANT

Graduate research assistant, preferably with research experience in physiological psychology or psychopharmacology, required for an MRC-supported project on behavioural effects of antischizophrenic drugs in rats.

Appointment for one year in the first instance. Salary and superannuation on University scale.

Apply with curriculum vitae and names of referees to Dr L.J. Herberg, Experimental Psychology Laboratory, Institute of Neurology, National Hospital, Queen Square, London WC1. 3148(A)

UNIVERSITY OF CAMBRIDGE

DIVISION OF VIROLOGY

DEPARTMENT OF PATHOLOGY

POSTDOCTORAL RESEARCH ASSOCIATE

Applications are invited for a five-year appointment with a team studying the molecular biology and genetics of influenza viruses. Previous post-doctoral experience in biochemistry, genetics or virology desirable. Starting salary up to £5,488 p.a. depending upon age and experience.

Applications with curriculum vitae and the names of two referees should be sent as soon as possible to Dr B.W.J. Mahy, Division of Virology, Department of Pathology, University of Cambridge, Laboratories Block, Addenbrooke's Hospital, Hills Road, Cambridge CB2 2QQ, from whom further details may be obtained.

RESEARCH TECHNICIAN

required as soon as possible to join a team studying the molecular biology of influenza viruses. The post is funded until September 1984. Qualifications: good degree, HNC or equivalent in biochemistry, genetics or micro-biology. Experience in tissue culture or virology advantageous. Starting salary up to £3,226 p.a.

Applications and enquiries to the Superintendent, Department of Pathology, Univeristy of Cambridge, Tennis Court Road, Cambridge CB2 1QP. Telephone 0223-64631, extension 27.

CSIRO AUSTRALIA

Post Doctoral Research Fellow

Centre for Animal Research and Development Bogor Indonesia

FIELD: Poultry Research

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees – 2400 of who are research scientists – located in Divisions and Sections throughout Australia.

DUTIES: An experienced poultry research scientist is required to lead a research programme on Chicken Management and Nutrition at the Centre for Animal Research and Development in Indonesia. The aim is to develop appropriate management and feeding systems for both the large and small-scale Indonesian poultry producer. The primary research effort will be directed to improving the efficiency of utilization of indigenous feedstuffs for chicken meat and eggs. The appointee will be expected to work closely with scientists working in an allied Duck Research Programme.

The Centre has excellent facilities and staff for nutritional studies with chickens and there is a modern analytical laboratory and veterinary section to provide back-up service. Existing studies have focused on the evaluation of local feedstuffs and development of new feed resources. The new appointee will be expected to further the research in these areas, and to consider the general problems of management of small chicken flocks at the village level.

QUALIFICATIONS: PhD and wide experience in the field of poultry research with an understanding of poultry nutritional experimentation. Experience in a tropical developing country an advantage. The training of Indonesian scientists will be an important responsibility and the successful applicant will be expected to show an interest and aptitude in this area.

SALARY: Research Scientist/Senior Research Scientist: $A15,916 to $A23,122 p.a.

TENURE: Subject to negotiation, but a minimum of 3 to 4 years is envisaged. The appointee may be offered an indenfinite appointment within CSIRO.

CONDITIONS: Overseas conditions of service apply with respect to housing and allowances. As training of local staff is an integral part of the duties, it is essential that the successful applicant attain a degree of fluency in Indonesian language. To this end, a language course will be arranged.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 1000/50 should reach:-

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 12th October, 1979.

Applications in U.S.A. and Canada should be sent to:- The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A. 3201(A)

STANFORD UNIVERSITY

GEOCHEMIST —PETROLOGIST

The Department of Geology in the School of Earth Sciences invites applications for a faculty position beginning September, 1980. Areas of interest include (but are not limited to) geochemical processes in the crust and mantle of the earth including isotope geochemistry, thermodynamics, kinetics, element distribution and phase equilibria studies. Teaching responsibilities might include graduate and undergraduate courses in geochemistry and igneous petrology. Level of appointment is open, but we are particularly interested in a creative young person, with a well-established record in research.

Applications should include (1) a resume of education, professional experience, and published research; (2) a brief statement of plans for future research, and (3) the names of 4 referees. Send to: Prof. J.G. Liou, Department of Geology, Stanford University, Stanford, CA 94305, by December 1st, 1979. Stanford University is an equal-opportunity/affirmative-action employer. W329(A)

UNIVERSITY OF DURHAM

DEPARTMENT OF APPLIED PHYSICS AND ELECTRONICS

LECTURER IN THE DEPARTMENT OF APPLIED PHYSICS AND ELECTRONICS

Applications are invited for the post of Lecturer in the Department of Applied Physics and Electronics tenable from 1st January 1980 or as soon as possible thereafter.

Salary will be at an appropriate point on the scale £4,333 to £8,992 plus superannuation benefits, according to age, qualifications and experience.

Candidates should have research and/or industrial experience in an area that will extend and complement the present Departmental interests in solid state physics and in electronics.

Applications (three copies) naming three referees should be submitted to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, not later than Monday, 22nd October, 1979. 3195(A)

British Museum (Natural History) London

Protozoologists

The British Museum (Natural History) is an institution for taxonomic research and an educational focal point for the public. The main aim of the research is to produce definitive accounts of the world's animals, plants and minerals as well as the preservation of an extensive collection of fossils.

RESEARCH ON CILIATED PROTOZOA

This post offers an experienced protozoologist the opportunity to carry out specialist taxonomic studies on marine benthic ciliated protozoa. There are excellent facilities for experimental culture work and light and electron microscopy.

Candidates, normally aged under 32, should have a good honours degree or equivalent in a relevant biological science. At least 2 years' postgraduate experience is required, part of which must be in protozoology.

Appointment as Senior Scientific Officer £6,655 to £8,640 or Higher Scientific Officer £5,505 to £6,990; (to become £7,110 to £9,485 and £5,875 to £7,515 respectively from 1.1.80). Level of appointment and starting salary according to qualifications and experience. Promotion prospects. Non-contributory pension scheme.

TAXONOMIC RESEARCH ON FRESHWATER CILIATED PROTOZOA

As a member of a small research team the successful candidate will be actively involved with taxonomic studies on freshwater ciliated protozoa.

Candidates, normally aged under 27, should have a good honours degree or equivalent in zoology or microbiology or related discipline. Some experience of protozoology advantageous.

Appointment as Scientific Officer. Starting salary (according to qualifications and experience) within the range £4,065 to £5,865 (to become £4,370 to £6,265 from 1.1.80). Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by 5th October 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). *Please quote ref: SB/61/DK.* *3172(A)*

RESEARCH OFFICER

Department of Chemistry

(Ref: CH/157)

NIBSC is an Institute concerned with the standardisation and control of biological substances used in medicine and is a WHO laboratory for biological standards. The work of the Institute is well supported by research.

The post is in the laboratory concerned primarily with the chemical and physical analysis of peptides and enzymes. A range of techniques is employed, including uv and fluorescence spectroscopy, all forms of chromatography and electrophoresis, and enzyme assay procedures. Applicants should have a degree in an appropriate discipline. Experience in some of the techniques mentioned would be advantageous.

Salary, depending upon age and experience, on the scale £3,715 to £5,259 p.a. (pay award pending), including London Weighting, plus superannuation benefits.

Please write or telephone for further details and an application form, quoting reference CH/157, to the Personnel Officer, NIBSC, Holly Hill, Hampstead, London NW3 6RB (Tel: 01-435 2232, Extension 200). 3188(A)

National Institute for Biological Standards and Control

UNIVERSITY OF BRISTOL

SCHOOL OF VETERINARY SCIENCE

A POSTGRADUATE RESEARCH WORKER

is required to join a group working on mucosal immunity in the Department of Animal Husbandry, Langford. The major study will be the development of hypersensitivity mediated tissue damage following oral presentation of antigens.

The project, funded by the Agricultural Research Council, is for a three year period, leading to a higher degree. Salary will be based on University scales.

Applications, giving the names and addresses of two referees, should be sent to The Professor of Animal Husbandry, Langford House, Langford, Bristol BS18 7DU. 3190(A)

UNIVERSITY OF QUEENSLAND

Australia

LECTURER IN PHARMACY

Must qualify for pharmaceutical registration and have appropriate higher degrees. Should have proven ability in Clinical Pharmacy and Pharmacy Practice. Will be responsible for teaching Clinical and Professional Pharmacy. Also liaison between Pharmacy, Medicine and teaching hospitals in Brisbane, and general administration. 8.10.79.

Salary: $A16,291 to $A21,401 p.a. Other Benefits: Opportunities to undertake programmes of special study, superannuation, housing assistance, travelling and removal expenses.

Additional information and application forms are obtainable from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

3147(A)

DEPARTMENT OF CHILD HEALTH

UNIVERSITY OF MANCHESTER

RESEARCH FELLOW IN ANATOMY

Postdoctoral Research Fellow required in multidisciplinary research team to organise new work in quantitative histology, mainly but not exclusively in the brain.

Enquiries with full curriculum vitae to Professor John Dobbing, The Medical School, Oxford Road, Manchester M13 9PT 3197(A)

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

South Kensington, SW7

RESEARCH TECHNICIAN GRADE 5

Duties include the operation and maintenance of analytical equipment, and the provision of assistance and advice in the use of research instruments.

Applicants must have considerable experience in the use of instruments appropriate to biological sciences, and preferably be qualified to HNC or advanced 1ST/CG standard.

Salary in range £4,224 to £4,844 inclusive (under review).

The post is superannuable. There is a generous sick pay scheme. The working week is 37 and a half hours. Five weeks annual holiday plus several days in addition to public holidays at Christmas and Easter Modern staff club and excellent facilities with sports centre and swimming pool Season ticket loan scheme after 6 months

Apply, in writing, to Mr C.L. Meredith, Departmental Superintendent, Zoology Department, Imperial College, SW7 2BB or telephone 01-589 5111 extension 2263.

3182(A)

CHARING CROSS HOSPITAL MEDICAL SCHOOL

(University of London)

LECTURER IN DEPARTMENT OF CHEMICAL PATHOLOGY

Applications are invited for the above post from either medically or non-medically qualified persons. Responsibilities include teaching and research and some health service duties for which it is expected that an appropriate honorary NHS contract will be granted.

Salary on scale £4,986 to £7,393 (under review) plus £354 London Weighting Allowance (medically qualified) or £4,333 to £8,992 plus £740 London Weighting Allowance (for those without a medical qualification).

Applications in writing with names and addresses of two referees or further information and application forms if required obtainable from The Secretary, Charing Cross Hospital Medical School, The Reynolds Building, St Dunstan's Road, London W6 8RP to be submitted by 12th October, 1979. (Ref: 050/2)

3178(A)

UNIVERSITY OF OTAGO

Dunedin, New Zealand

CHAIR OF EXPERIMENTAL ORAL BIOLOGY

The Council of the University of Otago invites applications for appointment to the foundation Chair of Experimental Oral Biology in the Department of Oral Biology in the Faculty of Dentistry, University of Otago.

Professorial salaries are fixed at various points within a present range from NZ$23,865 to $33,865 per annum according to whether the appointee holds dental, medical or other qualifications; increases are pending.

Further particulars are available from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar, University of Otago, P.O. Box 56, Dunedin, New Zealand. Applications close on 31 October, 1979.

3183(A)

UNIVERSITY OF BRISTOL

SCHOOL OF CHEMISTRY

GRADUATE RESEARCH ASSISTANT

Applications are invited from plant biochemists or plant biologists for this post to undertake research into the identification, photo-control of levels, and metabolism of gibberellins in plant leaves and etioplasts. The post which is funded by ARC is tenable for three years at a salary of £3,775 to £4,333 (Scale effective from 1st October, 1979 and subject to further review). The successful candidate will be encouraged to register for a higher degree.

Applicants should send a curriculum vitae and names of referees as soon as possible, to Professor J. MacMillan, School of Chemistry, The University, Bristol BS8 1TS. 3164(A)

THE UNIVERSITY OF SYDNEY

LECTURESHIPS (2) IN PHARMACOLOGY

Appointees will be responsible for conduct and development of teaching and research in neurochemistry and neuropharmacology in Department of Pharmacology. Research interests in mammalian central nervous system are desirable and willingness to participate in collaborative multidisciplinary research with Professor G.A.R. Johnston on amino acid neurotransmitters would be welcomed.

The positions are expected to be filled by probationary appointments of three years capable of leading to tenure, but if all the University's requirements for tenure are deemed to be satisfactorily met, tenure may be granted at time of appointment.

Salary range: $A16,291 to $21,401 p.a.

Applications including list of publications, curriculum vitae and names of three referees by *19 October 1979* to the Registrar, University of Sydney, NSW 2006, Australia, from whom further information available. Information also available from Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. 3184(A)

MEDICAL RESEARCH COUNCIL

Newcastle Upon Tyne

NEUROENDOCRINOLOGY UNIT

NEUROCHEMIST

An experienced neurochemist is required to join the recently established MRC Neuroendocrinology Unit at Newcastle General Hospital. The person appointed will be expected to lead a group working on the biochemical properties of peptidergic neurones, their interactions with other types of nerve-cell and possible involvement in clinical disorders of the nervous system. The post will be available from April 1980, and appointment will be to the Council's non-clinical Scientific Staff at Grade I (£6,757 to £8,452) or, in the case of an exceptional candidate, an appointment at Senior Grade (£8,182 to £10,097) would be considered.

Potential applicants should write, in the first place, to the Director, Dr J A Edwardson, at the MRC Neuroendocrinology Unit, Newcastle General Hospital, Westgate Road, Newcastle upon Tyne, NE4 6BE. 3198(A)

MEDICAL LABORATORY Scientific Officer required in Bacteriology Department for research in development of automated techniques for identification of bacteria using enzyme assays. Some experience in bacteriological and/or biochemical techniques preferred. Post is grant-funded for initial 2 years. Applicants should have minimum HNC, AIMLS, BSc or equivalent. Salary within scale £3,357 to £4,266 + £354 p.a. London Allowance. Apply with full curriculum vitae and names of 2 referees to The Secretary, St. Mary's Hospital Medical School, Paddington, London W2 1PG quoting Ref MLSO/SB/B/N. 3166(A)

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL

(University of London)
Denmark Hill, London
SE5 8RX

JUNIOR MEDICAL LABORATORY SCIENTIFIC OFFICER 'B'

required for the Chest Unit in this Medical School. Work will involve contact with patients and assisting doctors with research into diseases of the lung.

Minimum requirements, 5 'O' levels, 4 in Science subjects including maths, day release available. Post suitable for school leaver.

Salary according to age, qualifications and experience.

Applications, in writing, giving full details should be sent to the Secretary of the Medical School at the above address. Closing date 28th September, 1979. 3181(A)

CSIRO AUSTRALIA

Research Scientist

Division of Animal Production Sydney

Field: Endocrine Control of Mineral Metabolism.

CSIRO has a broad charter for research into primary and secondary industry. The Organization has approximately 7,000 employees — some 2,400 of whom are research and professional scientists — located in Divisions and Sections throughout Australia.

The Ian Clunies Ross Animal Research Laboratory is the Headquarters of the Division of Animal Production and is situated at Prospect, 20 miles west of Sydney NSW.

General: The Division has six broadly-based programmes of research on tropical animal production, strategic nutrition of livestock, skin and fleece biology, mineral requirements for livestock production, improvement in reproductive efficiency, and animal breeding and genetics, and has laboratories in Rockhampton, Armidale, Sydney and Perth.

Duties: These would involve the initiation of research projects dealing with the metabolism of phosphorus and calcium in ruminants (sheep and cattle). Emphasis will be placed on mechanisms controlling the movement of calcium and phosphorus within and between the various compartments in the body. This could embrace investigation into the hormonal regulation of intestinal absorption, bone resorption, salivary secretion and renal excretion. Developmental changes in these processes should also be considered.

Qualifications: PhD degree in an appropriate field or equivalent, with experience in the field of phosphorus and calcium metabolism in ruminants. A thorough biological knowledge should be combined with experience in tracer and compartmental analysis.

Salary: Research Scientist or Senior Research Scientist: $A15,916 to $A23,122 p.a. An outstanding applicant may be offered appointment at a higher level.

Tenure: Indefinite with superannuation.

Location: The position will be located at Prospect, initially, but may later be moved to Rockhampton, Queensland.

Applications in duplicate, stating full personal and professional details, the names and addresses of at least two professional referees, and quoting reference number 245/727 should reach: —

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 12th October, 1979.

Applications in U.S.A. and Canada should be sent to: The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, NW, Washington, DC, 20036, U.S.A.

3168(A)

JUNIOR TECHNICIAN

Department of Antibiotics

(Ref: AB/007)

to work in a laboratory concerned with the standardisation and control of antibiotics used therapeutically and to assist in the development of suitable analytical methods.

Candidates should possess or be studying for an HNC in one of the biological sciences. Microbiological laboratory experience would be an advantage.

Salary, depending on qualifications and experience, on the scale £2,892 to £5,034 (pay award pending) including London Weighting, plus superannuation benefits.

Please write or telephone for further details, and an application form, to the Personnel Officer, National Institute for Biological Standards and Control, Holly Hill, London NW3 6RB (telephone 01-435 2232, ext 200), quoting Reference No. AB/007.

National Institute for Biological Standards and Control

3187(A)

Microbiologist

Key involvement in advanced foods research

£10,000 + benefits Midlands

A substantial multi-million annual research budget is a clear indication of the strong commitment of our client to the development of new or improved products to meet the changing demands of the marketplace. It's a policy which has placed the company at the very forefront of food microbiology technology, one which at the same time affords considerable scope for original and challenging work in a progressive research environment.

With a minimum of 2 years' research experience and ideally an interest in the industrial applications of microbial ecology, you will be heading key research projects in the preparation and preservation of foodstuffs. As well as the more formal aspects of microbiological research this includes liaison with universities, research establishments and other professional bodies, and you will be providing a specialist consultancy service to other members of the R & D team.

Aged 26-32, you should have a good honours degree — preferably a PhD. A knowledge of microbial ecology, food microbiology or preservation technology would be an advantage. *Ref: W4936/N*

Replies will be forwarded direct, unopened and in confidence to the client unless addressed to our Security Manager listing companies to which they may not be sent. They should include comprehensive career details not refer to previous correspondence with PA and quote the reference on the envelope.

POST-DOCTORAL RESEARCH ASSISANT required in Department of Microbioloy to work on a three-year M.R.C. project on latency of human papovaviruses. Suitable for biochemist or virologist with experience in nucleic acid research. Salary not less than £4,262 plus £502 London Allowance for suitably qualified person. For further information telephone Dr McCance (01-407 7600 ext. 3376). Apply in writing, with full curriculum vitae, to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. M.C.5. 3078(A)

UNIVERSITY OF SHEFFIELD
ELECTRON MICROSCOPY TECHNICIAN (Grade 5)
required for the
DEPARTMENT OF HUMAN BIOLOGY & ANATOMY

Applicants should have experience in the operation, and at least basic maintenance of transmission electron microscopes. Experience in biological specimen preparation, while valuable, is not essential. Salary on scale £3,700 to £4,320 p.a.

Please send details of qualifications, experience and the names of two referees to the Administrative Officer (Personnel), (Ref. S1362/N), or write informally to Professor R. Barer, Department of Human Biology and Anatomy, the University, Sheffield S10 2TN. 3191(A)

POST-DOCTORAL POSITION available involving research in DNA replication in mammalian cell-virus systems. Salary: $16,000. Please send Curriculum Vitae to: Mrs Lucy Luckhardt, Sloan-Kettering Institute, Walker Laboratory, 145 Boston Post Road, Rye, NY 10580. W354(A)

UNIVERSITY OF LEICESTER
DEPARTMENT OF BIOCHEMISTRY
POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a postdoctoral research assistantship supported by the MRC to work with Dr D Critchley on cell surface changes and malignancy. The project is directed toward investigating the possible relevance of loss of complex glycolipids to other aspects of the malignant phenotype, including loss of fibronectin. Experience in cell culture and membrane biochemistry is desirable but not essential.

The appointment will commence as soon as possible; the post is most suited to candidates with at least 1 or 2 years postdoctoral experience, although recently qualified candidates will be considered. The salary will commence in the range of £4,333 to £5,199 depending on the candidate's age and experience.

Applications including curriculum vitae and the names of two referees should be sent to Dr D Critchley, Department of Biochemistry, University of Leicester, Leicester LE1 7RH. 3173(A)

LABORATORY SCIENTIFIC OFFICER required in Department of Microbiology to work on a three-year M.R.C. project on latency of human papovaviruses. Experience in biochemical aspects of virology essential. Salary for qualified Laboraory Scientific Officer not less than £3,261 (under revision) plus £354 London Weighting. Apply in writing, stating age and giving details of qualifications and experience, to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. M.C.4. 3077(A)

UNIVERSITY OF DUNDEE

Applications are invited from candidates who hold a good Honours degree in Biochemistry or related subject for appointment as a

RESEARCH ASSISTANT

in the University Department of Surgery at Ninewells Hospital and Medical School. The successful applicant will join a team investigating certain biochemical aspects of breast cancer. The appointment is supported by a SHERT grant and will be available for three years from 1st October, 1979 or some other agreed date. Initial salary at an appropriate point within the range £3,775 to £4,333. Superannuation under USS. Possibility of registration for a higher degree.

Applications, quoting Reference EST/81/79J and containing full details of qualifications and experience, and the names of three referees, should be sent to The Secretary, The University, Dundee DD1 4HN by 5th October 1979. Informal enquiries may be made to Dr P.R. Baker, Department of Surgery, Ninewells Hospital and Medical School, Dundee. 3153(A)

PLYMOUTH POLYTECHNIC
SCHOOL OF ENVIRONMENTAL SCIENCES
RESEARCH ASSISTANT IN SEDIMENTOLOGY/PALAEOECOLOGY

To investigate the lithostratigraphy, biostratigraphy, sedimentology and palaeoecology of the Upper Greensand (Cretaceous).

Intending applicants should have a good honours degree in the geological sciences.

Research assistants are normally required to register for a higher degree, although post doctoral applicants will be considered.

Appointments are for a period of two years, with a possibility of a third year (fixed term contracts). **Salary will be £3,480 for postgraduates or £3,780 post-doctoral (or equivalent) with annual increments of £250.** Application forms, returnable by *5 October 1979*, together with further particulars, from the **Personnel Officer, Plymouth Polytechnic, Drake Circus, Plymouth PL4 8AA.** 3179(A)

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
ACADEMIC DEPARTMENT OF PHARMACOLOGY
POST-DOCTORAL RESEARCH FELLOW IN RESPIRATORY PHARMACOLOGY

A post-doctoral Research Fellow with a physiological or pharmacological background is required to work on the actions of adrenoceptor blocking drugs on the lung. Training in *in vivo* techniques for measuring lung mechanics will be given.

Salary from £4,333 per annum plus £740 London Allowance.

For further details please contact Dr J Maclagan, Academic Department of Pharmacology, RFHSM, Clinical Sciences Building, Pond Street, NW3 2QC.

The closing date for applications is 12 October, 1979. 3194(A)

The Queen's University of Belfast
RESEARCH ASSISTANTS
Department of Applied Mathematics and Theoretical Physics

Research Assistant posts funded by the Science Research Council are available at both postdoctoral and postgraduate level for research in Atomic and Molecular Physics. The posts are tenable for both two and three year periods commencing 1st October 1979, or as soon as possible thereafter. Successful applicants will participate in the theoretical study of atomic collision processes of relevance in astrophysics, laser physics and fusion physics.

Applicants must have a good honours degree in Physics or Applied Mathematics and some experience of the practical use of computers. A knowledge of Atomic collision physics would be an advantage.

Commencing salary will be: Postdoctoral: £4,911; Postgraduate — range: £3,777 — £4,335.

Curriculum vitae, giving the names and addresses of two referees should be sent to the Personnel Officer, The Queen's University of Belfast, BT7 1NN, Northern Ireland. Closing date: 28th September, 1979. 3152(A)

CSIRO AUSTRALIA

Postdoctoral Research Fellow

Division of Land Resources Management Perth

Field: Physics and Chemistry of Forest Soils.

CSIRO has a broad charter for research into primary and secondary industry. The Organization has approximately 7,000 employees — some 2,400 of whom are research and professional scientists — located in Divisions and Sections throughout Australia.

General: The Division does research for the better management and husbanding of land and water resources. This includes environmental and societal implications of resource management in pastoral, agricultural, forested and near urban areas. One research programme based in Perth, W.A. is specifically studying the effect of using forested lands on the future productivity and conservation of forest resources. The appointee would be a member of this group.

Duties: To initiate research into the environmental consequences of intensive forest harvesting, in particular the effects of site characteristics and harvesting practices on soil compaction, erosion, and sediment and nutrient transport.

Qualifications: PhD or equivalent in an appropriate field of study.

Salary: Research Scientist: $A15,916 to $A19,509 p.a.

Tenure: 5 years.

Applications in duplicate, stating full personal and professional details, the names and addresses of at least two professional referees, and quoting reference number 284/102 should reach:—

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 12th October, 1979.

Applications in U.S.A. and Canada should be sent to: The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, NW, Washington, DC, 20036, U.S.A.

3169(A)

UNIVERSITY OF BRISTOL

Long Ashton Research Station

REQUIRED IN THE FOOD AND BEVERAGES DIVISION:—

POST A — MICROBIOLOGIST OR MICROBIAL BIOCHEMIST to investigate the effect of permitted preservatives and naturally occurring antimicrobial factors on the growth of wine spoilage yeasts and bacteria.

POST B — NATURAL PRODUCTS CHEMIST to investigate the formation of polymeric pigments from anthocyanins and phenolics and their stability in wines. Research with purified components in model systems to determine the causes of instability will be correlated with structural studies of the polymers.

POST C — NATURAL PRODUCTS CHEMIST to investigate the formation of polymeric pigments from anthocyanins and phenolics in fortified wines. Recent work shows such polymers can affect maturity, quality and resistance to microbial spoilage.

Minimum qualifications: 2(1) Honours degree or equivalent; Post A in microbiology or microbial biochemistry; Posts B and C in natural products chemistry. At least two years' postgraduate experience, preferably with a higher degree, or equivalent experience required for all 3 posts.

Posts A and B financed by industry on a long term basis. Post C financed by industry for 3 years initially with a possibility of an extension for a fourth. All in the Higher Scientific Officer grade (£4,727 p.a. rising to £5,097 p.a. from 1.1.80 to a maximum of £6,737 p.a.). Starting salary according to qualifications and experience. Non-contributory pensions scheme.

Further particulars and application forms from the Secretary, Long Ashton Research Station, Long Ashton, Bristol, BS18 9AF, to whom applications should be sent by 5th October, 1979.

Biochemist -Development Role around £6500

Due to further expansion, we need an able versatile life scientist to play an important role in development work associated with the production of our clinical assay systems. This new position calls for strong theoretical and practical skills as the work will involve many aspects of new product development and trouble-shooting.

Protein chemistry, radiolabelling techniques, freeze-drying methodology and assessment of new plant and equipment are all important features of the work.

This position will appeal to life science graduates who have had further experience and/or research training either in clinical chemistry or allied areas of biochemical research. It could provide an interesting career move to a research scientist wishing to broaden his/her development interests within a production environment.

The Company is based at Amersham but has a completely new production facility under development at Cardiff and this post will transfer to Cardiff during 1980. Our continued growth as an international organisation is reflected by a turnover of around £40m per annum and our increasing influence in a wide range of world markets.

Attractive benefits package includes assistance with relocation expenses, where appropriate.

Please telephone Dr. Stewart Allinson on Little Chalfont (02404) 4444, ext. 3908 for an application form, or write to him with concise career details at:

universit college o swansea

Histology Technician

Applications are invited for the vacancy of **Histology/Micotomy Technician, Grade 5,** in the **Department of Zoology.** The duties of the post will include processing tissues, cutting serial sections, staining and mounting slides for teaching and research purposes, sharpening microtome blades, caring for microscopes and allied equipment, together with some general laboratory work.

The salary will be on the scale £3,700 to £4,320 per annum.

Application forms may be obtained from the Personnel Officer, University College of Swansea, Singleton Park, Swansea, SA2 8PP, to whom they should be returned by *Tuesday, 25th September, 1979.* 3200(A)

British Nutrition Foundation

The BNF combines the expertise of leading medical, academic, governmental and industrial experts in its educational and research activities.

There are two vacancies for persons of high ability:

SENIOR SCIENTIFIC OFFICER (SSO)
SCIENTIFIC INFORMATION OFFICER (SIO

The SSO will have a good honours degree and several years relevant post-graduate experience. The varied work will include 'in depth' studies and the preparation of reports for publication.

The SIO will have a good honours degree or other relevant qualification and experience, and must be capable of explaining matters relating to food, nutrition and health in simple terms, by written and spoken word to health and education professionals and to lay persons.

Applications should reach the Secretary, British Nutrition Foundation, 15 Belgrave Square, London SW1, before Monday 1 October 1979.

3205(A)

PLYMOUTH POLYTECHNIC
School of Maritime Studies
RESEARCH ASSISTANT IN ASTRONOMY

To analyse data connected wit magnetic field of the Milky Way. Ar interest in computing and astronomica data analysis is essential. Applicant should have a good honours degree i Physics, Mathematics or Astronomy. Register Assistants are normall required to register for a high degree although post doctoral applicants wi be considered.

Appointments are for a period of years, with a possibility of a 3rd yea (fixed term contracts). *Salary will b £3,480 for Post Graduates or £3,78 Post Doctoral (or equivalent) wit annual increments of £250.*

Application forms, returnable by *12t October 1979* and further particulars to *Personnel Officer, Plymout Polytechnic, Drake Circu Plymouth, Devon PL4 8AA.* 3209(A

INSTITUTE OF DERMATOLOGY

(University of London)

SENIOR TECHNICIAN

required to assist in the running of a VG 305/2015 Mass Spectrometer/Data System. Experience in the field of quantitative organic gc-ms would be an advantage. Salary within the range of £5,370 to £6,939 (inclusive of London weighting).

Applications in writing, enclosing a c.v. to Professor M.W. Greaves, Institute of Dermatology, Homerton Grove, London E9 6BX. **3199(A)**

ROYAL HOSPITAL FOR SICK CHILDREN
Edinburgh

DEPARTMENT OF PATHOLOGY

POSTDOCTORAL RESEARCH FELLOW

required for work on the expression of enzyme markers in milignant disease. The appointment is for one year in the first instance and the starting salary will be £4,622 (university range 1A).

Applications giving the names of two referees should be sent as soon as possible to:

The Secretary, Department of Pathology, Royal Hospital For Sick Children, Edinburgh, EH9 1LF. Tel. 031 667 1991 ext 270. 3206(A)

ASSISTANT: STRUCTURAL GEOLOGY, ETH Zürich

Applications are invited for a position as Assistant to Professor Ramsay for work on a research project "Tectonic and geophysical studies of the Helvetic Alps" supported by the Swiss National funds.

Applicants should hold a PhD or equivalent degree. The work will consist of field mapping of large and small scale tectonic structures, strain analysis, and laboratory studies of deformed Mesozoic and Tertiary sediments. An x-ray texture goniometer and Philips TEM 400 are available for this study. The position starts October 1 1979 and will end May 31 1981.

Further information will be sent on request. Applicants should send a curriculum vitae and the names of two references to Professor J.G. Ramsay, Geol. Inst., ETH Zentrum, CH 8092 Zürich Switzerland. W356(A)

Australian Institute of Marine Science

Research Positions

The Australian Institute of Marine Science was established as a Statutory Authority of the Commonwealth Government in 1974 and, in 1977, took occupation of a modern and comprehensively equipped laboratory complex at Cape Ferguson, near Townsville, well situated for studies in tropical marine science including phenomena at the land-sea interface, on the complex environment of the Great Barrier Reef and in the adjacent ocean. The ongoing programs of the Institute are augmented by active collaboration and interaction with visiting investigators. Staffing of the Institute is expanding to match developing commitments in comprehensive and coherent studies of the Great Barrier Reef environment, its living communities and their dynamic behaviour. Enquiries are invited from professional researchers interested in appointment to participate in such an investigation. Expertise is sought in the following fields: Physical, Chemical and Biological Oceanography, Reef Metabolism, Community and Population Ecology.

Duties: The appointees will be expected to join effectively in a group concerned at developing a fundamental understanding of the environment of the Great Barrier Reef and the ecology of its living communities including their organization, component interactions stability characteristics.

Qualifications: The appointee must possess PhD level qualifications and preferably experience demonstrably applicable to the research problem outlined. Levels of appointment area open. Tenure will be offered if appropriate. However, those who might wish collaboration for a fixed term are also encouraged to indicate their interest.

Applications should be accompanied by a complete C.V., the names of at least 3 but no more than 5 referees and should be forwarded to the address given below no later than 31 October 1979.
The Secretary, Australian Institute of Marine Science, P.M.B. No.3, M.S.O. Townsville, O. 4810, Australia. 3170(A)

UNIVERSITY OF AARHUS

Denmark

A one year temporary position as adjunkt/lektor (associate professor or assistant professor according to qualifications) with possibility of extention is vacant at the Department of Molecular Biology and Plant Physiology starting January 1, 1980.

The successful applicant will be required to work in the area of symbiotic nitrogen fixation in higher plants as part of a group within the department. The research will primarily deal with the molecular genetics of Rhizobium. Applicants with research experience in bacterial and molecular genetics will be preferred.

The successful applicant must, on equal terms with the other members of the staff, share the teaching responsibilities — from first-year level to supervision of graduate and post-graduate students. Further information can be obtained from professor K.A. Marcker, phone Denmark (06) 12 51 77.

Applications containing curriculum vitae, information on scientific and educational activities, a list of publications plus wherever possible 3 copies of published material, and any additional information relevant for the evaluation of the applicant's scientific and educational qualifications should be sent to the Faculty of Science, University of Aarhus, Ndr. Ringgade 1, DK-8000 Århus C, Denmark, before October 7, 1979.

The report of the evaluation committee will be sent to all applicants. W355(A)

GLASSHOUSE CROPS RESEARCH INSTITUTE

requires

SCIENTIFIC LIAISON OFFICER.

Duties include arrangements for and reception of visitors, assisting in organising Open Days, preparation and presentation of exhibits, answering queries, assisting in preparation of publications. Appointee should have sound knowledge of horticulture.

Appointment in Higher Scientific Officer grade, salary £4,727 to £6,211 p.a. (£5,097 to £6,737 p.a. from 1 January 1980). Starting salary depending on qualifications and experience. Applicants should have Honours degree in relevant scientific subject with at least three years post-graduate experience. Non-contributory superannuation scheme. Further details and application forms on request.

Applications to Secretary, Glasshouse Crops Research Institute, Worthing Road, Rustington, Littlehampton, West Sussex, BN16 3PU, by 1 October 1979. 3211(A)

The Research Unit of Organon Laboratories Limited, Newhouse is an integral part of the Scientific Development Group of Organon International a major international pharmaceutical company based in the Netherlands.

Applications are invited for the position of

Immunopharmacologist

in our Biochemistry R&D Laboratories. This department is responsible for both exploratory and developmental research directed towards the production of new therapeutic agents for the treatment of chronic inflammatory disease. The experimental approach is mainly directed towards agents modifying the immune system so the appointment offers a challenging opportunity to join a young and enthusiastic interdisciplinary team working in this rapidly developing area of research.
Suitable candidates will already have at least 2-3 years post-doctoral experience in the immunopharmacology of chronic inflammation and will show the ability to direct the research of a group of 2-3 scientists and technicians.
The successful candidate will be expected to maintain and develop his expertise and reputation in the field by attendance at scientific meetings and by publication of his reserach results.
The initial salary will be based on qualifications and experience and will be commensurate with the responsibilities of the position. Conditions of employment are in keeping with good modern practice and assistance with relocation expenses will be available in appropriate cases.
Applications should be addressed to the Personnel Manager, Organon Laboratories Limited, Newhouse, Lanarkshire, ML1 5SH.

UNIVERSITY OF LONDON

British Postgraduate Medical Federation

CARDIOTHORACIC INSTITUTE

(associated with the National Heart & Chest Hospitals)

CARDIAC METABOLISM RESEARCH LABORATORIES

50 Wimpole Street,
London W.1.

A vacancy exists for a

RESEARCH ASSISTANT

to assist in a project concerned with the identification and mechanisms of beta-receptors in myocardial tissue. The project is suitable for a PhD thesis and registration for this higher degree will be encouraged.

Applicants should have a degree in Biochemistry (first or upper second class). The post is offered for a maximum of three years. Minimum salary £3,768 + £354 London Allowance (from 1.1.80: £4,125 + £354).

Application forms available on request from the House Secretary, Cardiothoracic Institute, 2 Beaumont Street, London W1N 2DX (telephone 01-486 3043). Closing date 5th October 1979.
(This is a re-advertisement and previous applicants should not re-apply). 3210(A)

FERMENTATION MICROBIOLOGIST

We are a large forest products R&D organisation, and are expanding our efforts on the conversion of wood residues to valuable products. Applicant should have a good honours degree, and preferably a PhD, in one of the biological sciences, together with specialised knowledge of fermentation processes, ideally in the area of biochemical engineering.

Duties will be to grow microorganisms on wood-based materials in laboratory fermenters, including continuous culture equipment. He will work closely with chemists on suitable pretreatments of the wood substrate and will be expected to devise techniques for screening, collecting and optimizing the yield of a variety of end products.

Salary open; fringe benefits generous. For further information please write to: Mr I B Flann, Forintek Canada Corp, 800 Montreal Road, Ottawa, Ontario, K1G 3Z5, Canada. W330(A)

FOR SALE and WANTED

FOR SALE: OPTOMAX (Micromeasurements) Modular Image Analyser including CPU, Power supply, Video Moniter, Flexidraw Module, Circular Variable Frame Module and Averaging Unit. Less than two years old; little used. Please contact: Ms Margaret Androu, Scott Polar Research Institute, Lensfield Road, Cambridge, CB2 1ER.

ASSISTANTSHIPS

UNIVERSITY OF GLASGOW

Kelvin Laboratory

POSTDOCTORAL RESEARCH ASSISTANTSHIP IN NUCLEAR STRUCTURE PHYSICS

Applications are invited for the above post based at the Kelvin Laboratory to work in close collaboration with a group of 6-8 physicists from the University of Edinburgh. This group is engaged in a variety of electro- and photo-induced nuclear reaction studies using the 30 MeV and 170 MeV electron accelerators at the Kelvin Laboratory.

The post is tenable for two years starting within six months of 1st October, 1979. Initial salary will be within Range 1A of the scales for Research and Analogous Staff (£4,333 to £5,488) depending on age and experience. Superannuation benefits will apply.

Applications, stating age, academic qualifications, research experience and giving the names of three referees, should be submitted not later than 12th October, 1979, to Dr. R.O. Owens, Department of Natural Philosophy, University of Glasgow, Glasgow, G12 8QQ, or to Dr D Branford, Department of Physics, University of Edinburgh, Edinburgh EH9 3JZ, from whom further details of the post may be obtained. In reply please quote Ref. No. 4507M. 3176(P)

KINGSTON POLYTECHNIC

NICKTRANSLATIONSYSTEM

The world's first. Packaged complete.

Naturally it is more convenient than assembling the components yourself. But even more important is its reliability.
For example, the *E.coli* DNA Polymerase I is cloned in our laboratories to ensure extremely high reproducibility. The dCTP, [α-^{32}P]- is tested for nick translation by our Biological Testing Laboratory. (Typical incorporation is 40%, and we guarantee 1 x 10^8 dpm/μg DNA.) The supercoil PBR322 Plasmid DNA control we use to test each lot of systems is included so you can check yours. Finally, the DNAse I, dNTP mixture, stop-buffer, and sterile deionized water are optimized for compatibility and stability. Approximately twenty assays can be run.
A bulletin describing this exclusive system is yours for the asking.

ELECTROPHORESIS
A state of the art report from Marine Colloids

SeaKem® Agarose is the preferred medium for electrophoresis

Marine Colloids is the world leader in agarose with more experience and more end-use-specific types of agarose than any other manufacturer. Tell us the properties you want and we'll supply the agarose you need. Ask for a copy of our catalog and price list.

GelBond™ film is making glass plates obsolete

GelBond is Marine Colloids' tradename for the new transparent, flexible, specially-treated polyester film* to which freshly-prepared agarose, agar and polyacrylamide gels adhere and remain adhered during use. Its advantages are convenience, permanence and firm adhesion of the gels throughout drying, staining, destaining and storage. Try it once and you'll never go back to glass. Only Marine Colloids offers GelBond film. Ask for a copy of our GelBond bulletin and price list and free samples.

*Custom manufactured for Marine Colloids by the 3M Co.

IsoGel™ (No EEO) Agarose. A breakthrough in ISOELECTROFOCUSING

The IEF procedure separates and concentrates proteins on the basis of minute differences in their isoelectric points. Until recently, the application of the IEF technique in continuous media was limited to polyacrylamide gels despite their notorious limitations. With the advent of IsoGel, the many familiar advantages of agarose are now commercially available in a gel medium having no electroendosmosis ($-M_r$). In addition and perhaps most important is its capability of direct and immediate extraction and focusing of proteins from biopsy tissue. Ask for a copy of our new instruction manual which describes the Agarose Isoelectrofocusing technique and provides a recommended procedure for protein analysis.

For Serum Protein Analysis, GelBond™ film with SeaKem® Agarose offers superior resolution plus

World leaders in Clinical Chemistry now recognize the superiority of SeaKem Agarose and GelBond film over cellulose acetate for routine serum EP. They have come to prefer the convenience, reproducibility, greater yield of diagnostic information and sharp, permanent records provided by SeaKem and GelBond. [AGAROSE GEL ELECTROPHORESIS, submitted by J.-O. Jeppsson, C.-B. Laurell and B. Franzén, Department of Clinical Chemistry, Malmö General Hospital, Sweden, is now a proposed selected method of the ASCC (Clinical Chemistry Vol. 25, #4, 1979)]

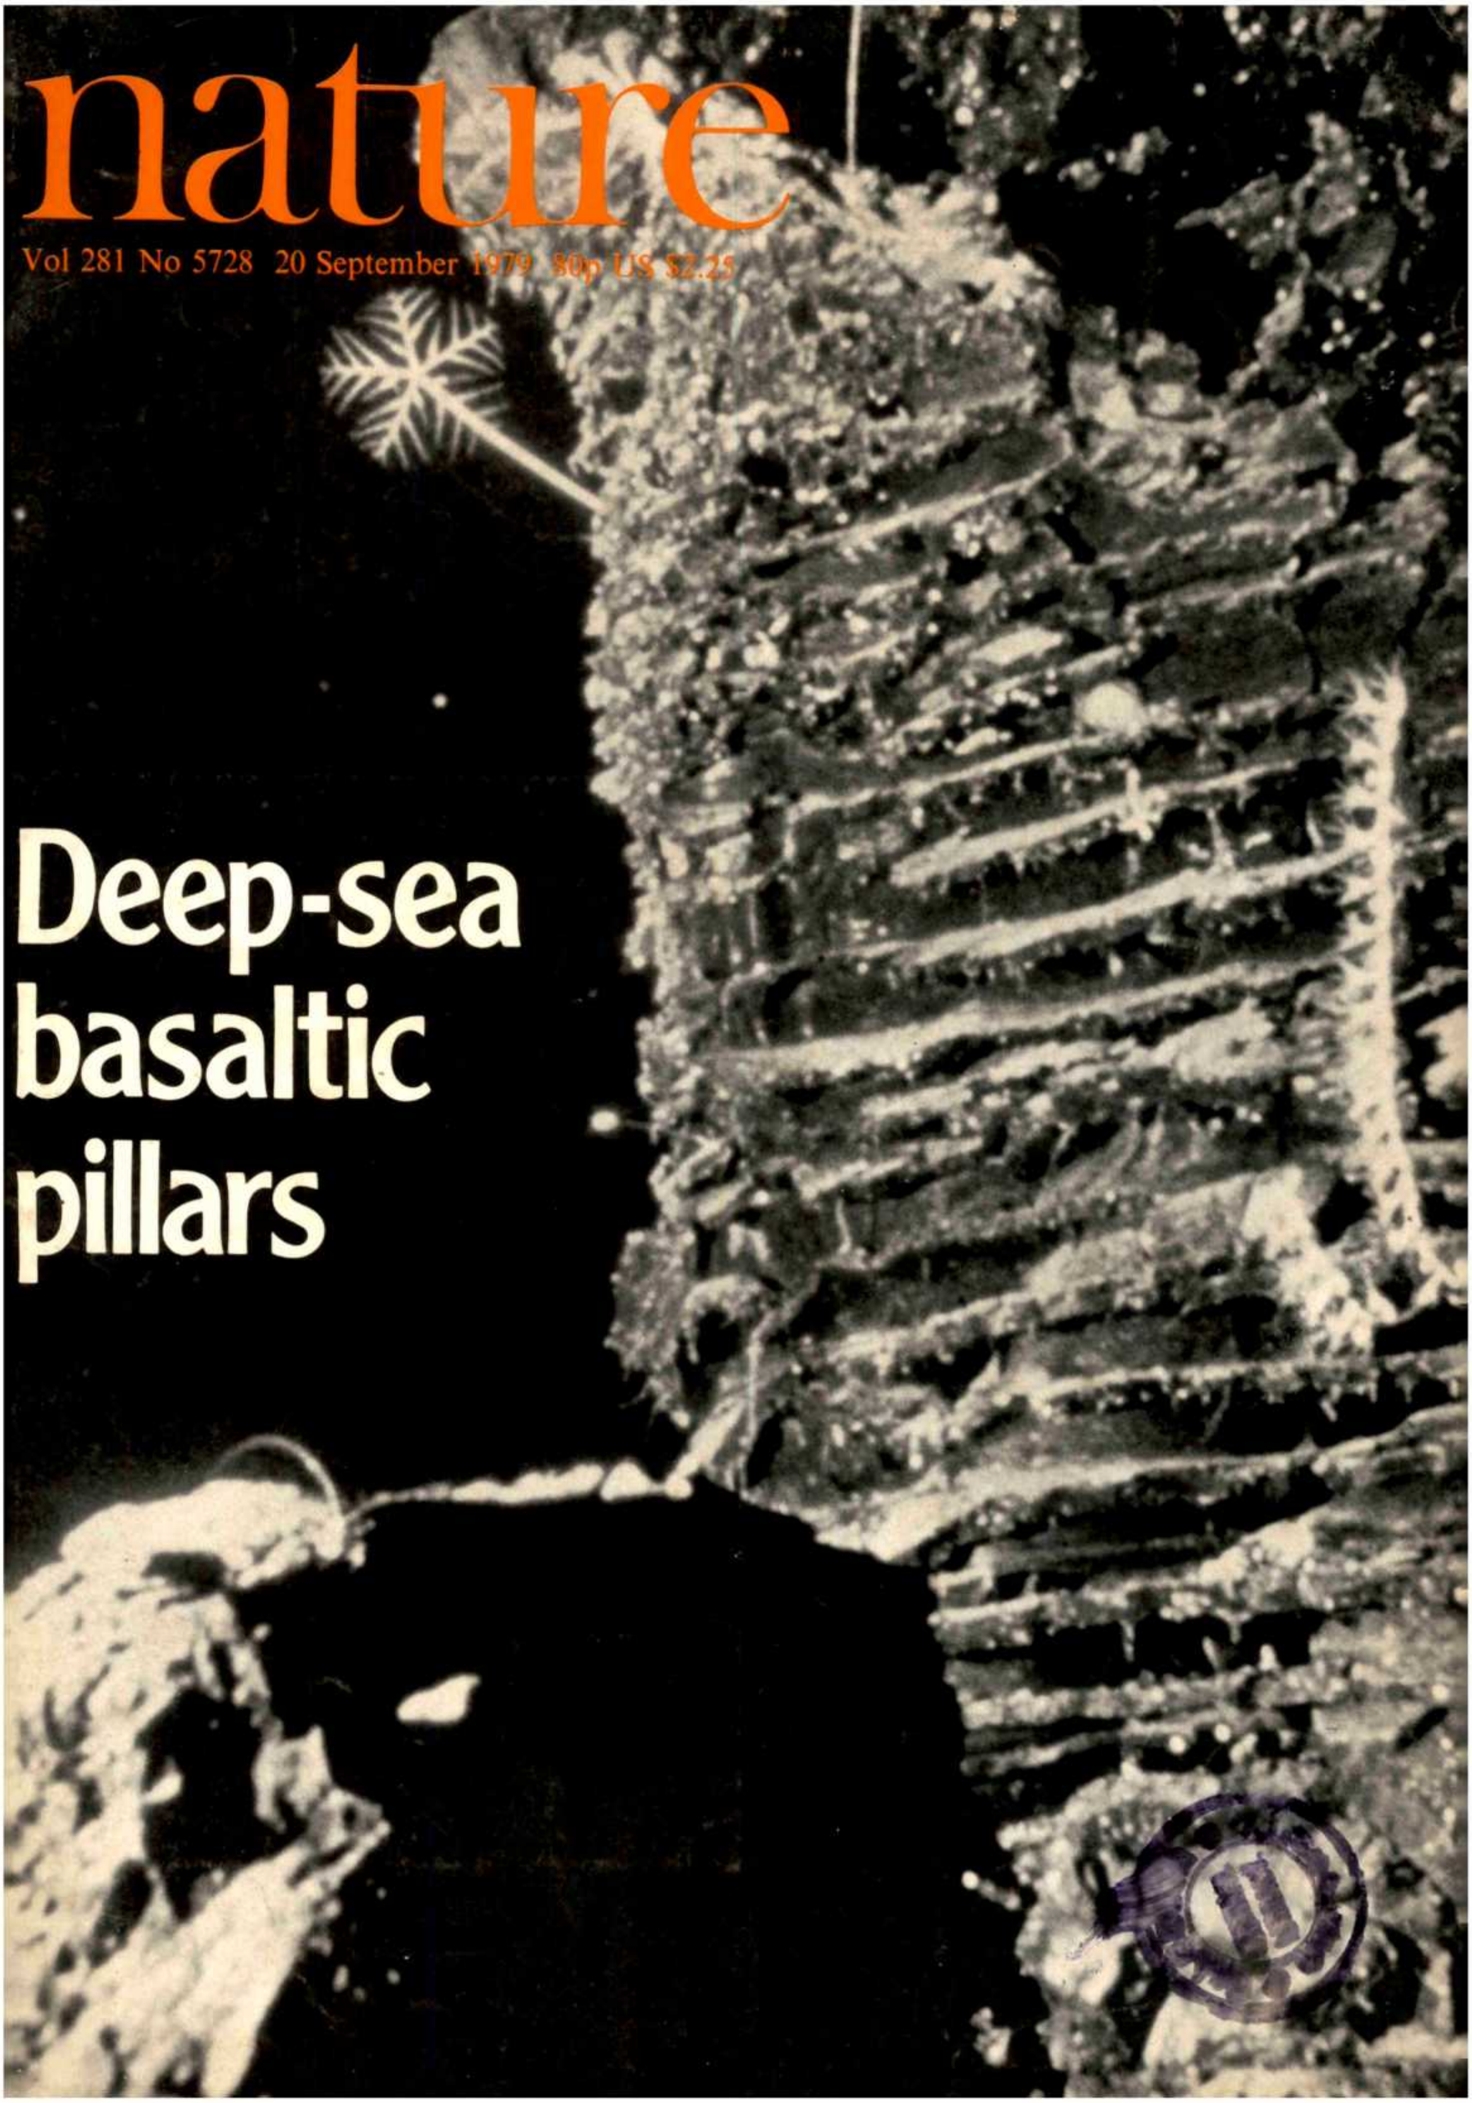
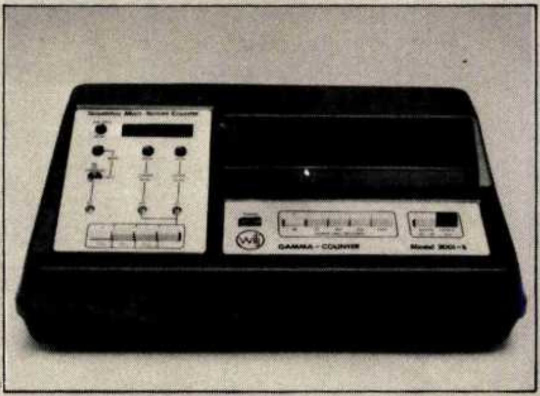
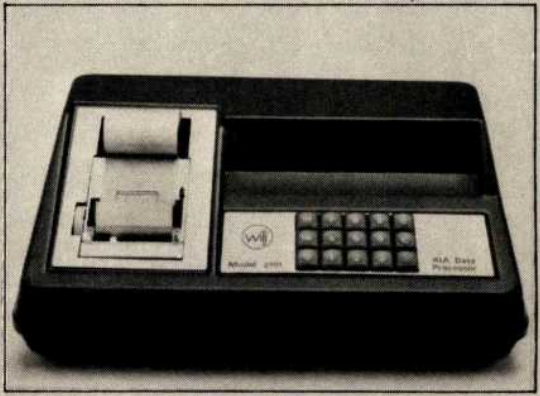
Deep-sea basaltic pillars



The British family Wilj announce two talented new members





Gamma Counter 2001-S

- 50mm Crystal, 50mm shielding
- Multiple-channel facilities (SMIC)
- Additional user variable window
- Digital display directly in KeV
- Accepts alternative external counting heads
- Incorporates our unique easy to calibrate system

RIA Data-Processor 2701

- Easy to use — it asks you the questions
- Dual-channel
- Choice of curve fits : Polylinear, Logit/log & Spline
- Statistical checks

These two new additions increase Wilj's long lead on other lower-cost RIA equipment. This combination can count and process **double-isotope kits** in one simple operation.
Higher energy isotopes can be counted with the larger crystal and increased shielding.

Data-processing is no problem with Wilj peripheral options. Teletypes, paper tape, data-logger and the Hewlett-Packard 9815A programmable calculator and software can all be accommodated.

Whichever combination you choose, all Wilj products come complete with an unconditional 2 year guarantee. (U.K. Only)

Above: Hemoglobin-oxygen equilibrium curve of normal human blood at 37° C and pCO$_2$ of 40mm Hg showing a P$_{50}$ = 26.0mm Hg.

HEM-O-SCAN®

Oxygen Dissociation Analyzer

Produces a continuous, complete hemoglobin-oxygen equilibrium curve in approximately 20 minutes from only two microliters of whole blood or hemolysate.

The Hem-O-Scan analyzer offers a major advance in techniques for the analysis of the oxygen carrying capacity of hemoglobin. It provides a significant time saving, and offers simplicity of operation.

The Hem-O-Scan analyzer equilibrates the sample with varying oxygen partial pressures and simultaneously records a continuous curve on an X-Y recorder.

The oxygenation of hemoglobin is monitored by dual-wavelength spectrophotometry and the oxygen partial pressure is measured by a Clark oxygen electrode.

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**,1 (1975) and **264**, v, 11 Nov. (1976).

HIGH PRECISION. LOW PRICE.

ALZET® minipumps now give you 8 days of precise, round-the-clock drug delivery for only $7.25, or less. And, with a wider range of solvent compatibility, you can deliver some previously difficult-to-solubilize agents.

These tiny, self-powered minipumps can be implanted in laboratory animals to deliver bioactive agents systemically or locally. And since they are small, minipumps can be used easily in animals as small as mice.

The price is now only $72.50 for a 10-pack of Model 2001 minipumps. Enough for a week-long study in 10 animals based on a delivery rate of 1 μl/hour. The Model 1702, which delivers 0.5 μl/hour for up to two weeks, is also available. To order minipumps, or to receive more information, call our toll-free number: 800/227-9953, or send in the coupon below.

AgI crystals

If our studies on them should happen to shed new light on how tooth, bone, and snow form, it would be nice

Our purpose here is not at all devious. It is simply to incline you favorably toward our trademark when buying film.

When you plunk down the money for a cartridge of Kodak film, a very small fraction of one of the pennies goes to pay Richard L. Daubendiek's salary and the expenses of his trip last year to Copenhagen to lecture an international conference on "AgI Precipitations: Effects of pAg on Crystal Growth." The professors and sundry academic types from various countries who attend such a conference couldn't care less about how we make film. Nor could Dr. Daubendiek tell them even if he knew all about it.

What Dick Daubendiek and a few of his associates do know a lot about is the traffic in ions between crystals and the solutions they sit in. Since our business has rested largely on the growing and behavior of small silver halide crystals, we feel we (and you) can afford Dick.

Although pure silver iodide crystals began to fade in importance as the basis of photography after Daguerre settled down with his 6,000 francs a year for ife from Louis Philippe, King of the French, they subsequently turned out o be just right for studies of nature's ules for assembling and disassembling rystals of all kinds—biological, meterological, or merely industrial.

Now suppose you arrange for a jet of silver ions to meet a jet of iodide ions in an aqueous solution of gelatin at 35°C, and suppose you vary their relative concentrations over a broad range. The size of the crystals that precipitate can be measured by electron micrography from carbon replicas shadowed with platinum-palladium, like the ones shown above that were formed at pAg 6.5 and consist of four hexagonal pyramids each. If you plot their mean size against pAg in a constant ionic environment, as Daubendiek has done here, why do you suppose you get that sharp cusp?

Kodak

His dashed line fits with earlier work represented by the solid line.

20 September 1979

Solar energy is a key to development

Earlier this year the Commission of the European Communities held a meeting in Varese, Italy, at which scientists and technologists of both developed and developing world discussed the potential for solar energy in the latter. This meeting had been preceded by five regional seminars in Nairobi, Bamako (Mali), Amman, Caracas and New Delhi. The papers of the conference have recently been published (*Solar Energy for Development*, Martinus Nijhoff, The Hague) and raise some interesting questions concerning a science and technology whose relevance to development is very close indeed.

In the developed world, it is going to be a very long haul for solar energy to supply a significant fraction of our needs — estimates generally range around a contribution of a few per cent at most by the year 2000. This slow rate of progress is less a reflection on lack of scientific and technological skills than on the enormous built-in momentum that modern industrialised society has which strongly resists major changes of course. The picture is very different in the developing world. There solar energy (in the form of direct heating, biomass and wind) is, and always has been, the dominant energy input, particularly in rural environments. In Africa, for instance, even by 1985 not one in ten of all villages will have an electric power supply.

In many ways this dependence on the sun should be regarded as a strength for the future, which should not lightly be yielded up to the blandishments of other sources, for the poorest people of the world can ill afford to get caught in the spiral of energy price increases. And in the long run, as Sir George Porter pointed out to the meeting, if and when the technology of chemical fuels is developed, it is the barren deserts of the world which could well become the ideal place for growing these fuels — and hitherto resource-poor countries could become major energy exporters. There is also a fairly hardnosed political reason why developed countries would be encouraging developing countries to think solar — that it might just head off some nations from thinking nuclear with all the complex ramifications that would bring.

All of this clearly adds up to a compelling case for the vigorous pursuit of more research and development into uses of solar energy. Favoured as many developing countries may be in their use of cheap uninterruptible energy from the sun, they cannot develop much further without demanding more energy from somewhere.

If solar energy is to be even more widely used in the developing world, two major obstacles will have to be overcome. The first is the lack of status for the subject. Someone who designs a new solar water heater or crop dryer or desalination plant may contribute far more to development than someone who works on an exotic theoretical problem in an academic environment. And yet the latter will get more acclaim, particularly from an international community. It is no surprise that the developing world only started to show strong interest in advancing solar science and technology when developed countries (and particularly the United States) went in for it in a big way. But even now, it is not at all clear that adequate intellectual resources are being devoted to the problems.

The second obstacle is the understandable feeling in most developing countries that research and development, if done at all, has to be done domestically. Collaborative regional centres of research, where they exist at all, often get the problems that have lowest priority. But the sort of questions raised in solar energy research rarely fit snugly to national boundaries, and there is every reason to pool resources over quite wide regions. Slowly this is being realised in Africa and Latin America, but there is much scope still for more effective collaboration, if only at the level of the exchange of information.

Solar energy could be a large ingredient in the economic advancement of the developing world. It offers a marvellous opportunity for the use of indigenous skills. Will the developing world take up the challenge? □

Environmental regulations under attack

The end of a decade is inevitably a period of taking stock, looking back at the impact of past actions and forward to their implications. Ten years ago the environmental attack on the unwelcome side-effects of rapid industrialisation was at its height. Environmental protests became an increasingly common event across the western world. Demonstrators' concerns ranged from the effects of pesticides on wildlife to the carcinogenic hazards of the workplace. In the US, Congress responded with legislation such as the Natural Environmental Protection Act of 1970, and the Occupational Safety and Health Act of the same year. And the air rang with 'end of an era' quotations about how society was learning from the error of its past ways.

We may be a few months early in bringing down the curtain on the 1970s. But in recent weeks, political events in the US have begun to overtake the calendar in signalling the end to the spirit which has pervaded much of the past decade — already referred to by some as the 'golden age of environmentalism'. Bold commitments to guaranteeing a clean and safe environment, with the federal government being given a prime responsibility for achieving each, are giving way to increasing calls to pass this responsibility back to the market plce and to the private sector. The effects of regulation on energy supply and on technological innovation are usually mentioned as the most important reasons for this shift. But both are backed by a growing anti-government tendency in US politics, with Washington's role as chief regulator placed squarely in the stocks.

Over this next three weeks we shall be running a series of news features on this trend and its implications for the future. In this issue we examine (page 168) the growing conflict between environmental and energy demands. Next week we shall look at the industrial response to recent moves in the fields of occupational health and safety. Finally we shall examine how, in the international nuclear energy domain, US attempts to control the spread of nuclear technology have met with, at best, only limited success.

We do not wish to speculate too much on what on the next decade has in store. But the movements of the past decade will occupy an important chapter in the history of the relationship between science and politics. The movements of the next are unlikely to be any less significant. □

0028-0836/79/380167-01$01.00

The end of the age of Aquarius?

Concerns about energy and inflation, linked to a conservative trend in US politics, are beginning to eclipse the moral commitment to a clean and safe environment characteristic of the past decade. In the first of three articles on how this has happened and what may follow, **David Dickson** describes how the energy issue has become a major threat to US environmental movements.

"Man can survive pollution; environmentalists can relax about that. The question is whether he can survive regulation." These words headed a full-page advertisement in the US national press last week for a new book, *Restoring the American Dream*, by best-selling author Robert J Ringer.

The sentiments are not new. Indeed such arguments have been frequently heard since concerns about the effects of pesticides on bird-life ushered in the environmental movement in the mid-1960s. And they have provided a constant back-drop to a decade of legislative measures designed to protect the US environment against the worst excesses of technological growth.

In the past few months, however, concerns about growing inflation and the security of future energy supplies have both helped to generate an anti-regulation bandwagon that is demanding a major rethink of this legislation and its effects — as well as laying the ground-work for a substantially different approach to environmental regulation in the 1980s.

As far as the administration is concerned, this will mean less emphasis on the government as a regulator of industrial activity, and greater emphasis on the market-place as the matrix for 'rational' decision-making on regulatory activities.

For the environmental movement, it means a shift from the essentially defensive posture which the movement has been adopting in recent years, capitalising on the gains made earlier in the decade, to one in which urgent action is now needed in most fields (except perhaps that of nuclear energy) to prevent the threat of a complete rout.

Two main factors have fuelled this anti-regulatory tendency. The first has been the argument that inflationary problems are directly linked to a decline in national productivity (which fell by an annual equivalent rate of 5.9 per cent in the second quarter of 1979); and that this is largely linked to a decline in technological innovation, itself due partly to increased environmental and health regulation.

"What started as a regulatory snowball ten years ago has become an avalanche, and innovation is one of its victims," Dr H D Doan, ex-president of the Dow Chemical Company, said at a meeting of the American Chemical Society in Washington last week. "George Orwell may not have been accurate in his predictions; but the regulators tend to confirm his foresight."

The second factor which has played a key role is the pressure on US politicians, following the Iranian oil crisis earlier this year, to be seen to be doing something about guaranteeing future energy supplies — if necessary at the expense of environmental considerations.

Two developments in particular have led to a qualitative rise in the energy *versus* environment debate. The first has been the push for a massive programme to stimulate the production of synthetic fuels as a substitute for imported oil, and the renewed emphasis on the use of coal, both of which,if not properly handled, could have a significant impact on factors such as the build-up of atmospheric CO_2.

The second factor, which many environmentalists fear could be even more damaging, is the president's decision to establish a top-level Energy Mobilisation Board. Of particular concern are the strong powers which many congressmen would like this board to have to over-ride federal and state environmental legislation in order to speed up major energy programmes.

The idea that there are necessary trade-offs between energy demands and environmental considerations is not new. Until relatively recently, however, the administration has sought to contain such debates within a framework of cost-benefit analysis, using economic pay-off as the means of weighing up the merits of one course of action against another.

Such analysis, for example, has been behind some recent decisions to relax certain aspects of clean air legislation. For example, many power companies are being squeezed between new limits on sulphur dioxide emissions, and the president's call to reduce oil consumption by half by 1990, largely through the use of coal; and cost-benefit analysis is being used as a prime tool to tackle such conflicts.

In the past few months, however, this approach has been overtaken by a more overtly political drive aimed at circumscribing the government's role in a range of activities. One of the first manifestations of this trend was California's decision last year to halve its property taxes, the famous Proposition 13; more recently, government regulators have become a prime target for political abuse.

According to a survey published in March by Opinion Research Corporation, for example, more than half of the general public feel that the costs of government regulation exceed the benefits. And by a margin of two to one, those interviewed said that there was a need for less rather than more government regulation.

With elections coming up next year, congressmen from both parties are eagerly responding to what they see as popular demands for less regulation — in many cases outstripping the administration's economists in their anti-regulatory fervour. In the last two weeks, for example, this tendency has become clear in four separate congressional actions.

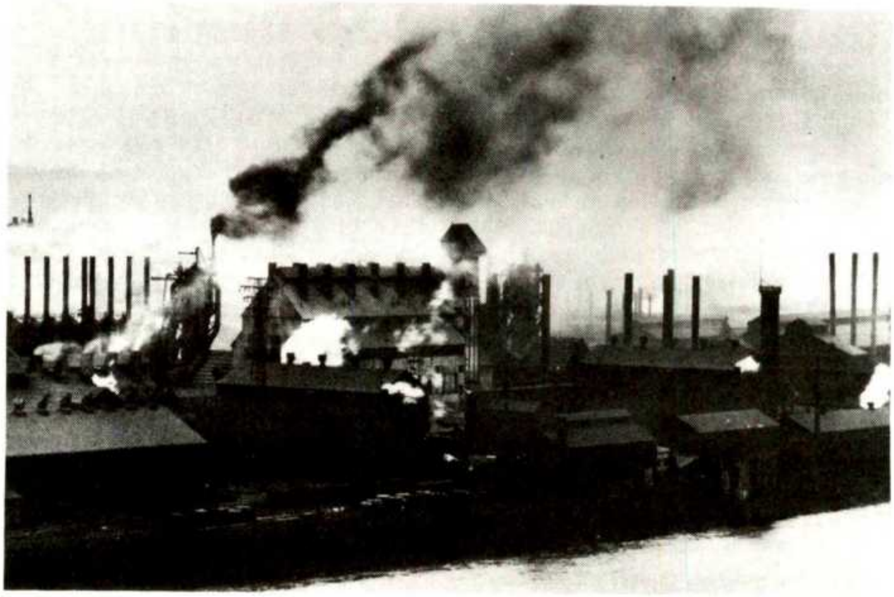
The first was an amendment by Senator Dale Bumpers (Dem. Arkansas) to a bill on the federal court system, requiring a federal agency to demonstrate the validity of a particular set of regulations in court every time that they are challenged. The amendment thus challenging the "presumption of validity" that now covers agency rules when challenged in court proceedings, making it easier for courts to overturn federal regulatory decisions.

The second decision was taken during a debate last Tuesday on a strip-mining bill, which would allow states to disregard regulations laid down by the Department of the Interior about making-good disturbed landscape. On the same day, the Senate also voted to allow the completion of the Tellico Dam, thus in effect agreeing to the extinction of the snail darter, whose status as an "endangered species" had previously led to a Supreme Court ruling that the dam should not be finished.

Perhaps the most significant decision, however, was taken by the House Commerce Committee. In discussing the role of the President's proposed Energy Mobilisation Board, the committee agreed that the board should have considerably stronger powers than the president had proposed, enabling it to waive environmental regulations.

Despite intense efforts by environmental

0028-0836/79/380168-02$01.00



lobbying groups, the committee approved a bill which would allow the board to recommend that the president waive any federal, state or local law blocking a high-priority energy project.

Environmentalists are supporting an alternative version of the bill under which, as originally proposed by the adminstration, the board would be merely able to speed-up procedural aspects of project approval; and one sympathetic congressman, Representative Tim Wirth (Dem. Colorado), has promised a "huge, huge battle" when the Commerce committee bill is debated by the full House.

Critics of the stronger version of the bill have been particularly concerned about the apparent support that this version is now receiving from the White House (even though administration officials claim that their support is at present essentially a bargaining device).

"If we are not careful, the Energy Mobilisation Board could threaten fifteen years of environmental work," says David Maselli, energy policy director for Friends of the Earth. He points to the low priority given to environmental considerations in the energy proposals with which President Carter emerged from his recent seclusion at Camp David; "it was close to the bottom line — so close to a 'worst case' guess about the outcome of Carter's deliberations that many environmentalists were genuinenly surprised," he says.

Maselli points out that environmental groups have not lost out on everything in recent legislative debates. They have had considerable success, for example, in slowing down the projected growth of the administration's proposed programme for synthetic fuels — an issue against which "we are standing as hard as we can" says Herb Epstein of the Solar Lobby — and have won acceptance for numerous solar energy and conservation measures.

But no-one denies that there are some major battles ahead. "I think it is going to be a hellish struggle, even to preserve the gains that we have won," says Epstein. And others are already saying that the 1970s may be looked back on as "the golden age of environmentalism."

Speaking at the ACS meeting last week, Dr Frank Press, director of the Office of Science and Technology Policy, indicated a shift in administration thinking when he said that he saw a "new philosophy" being pursued. This was one that recognised that the desired goals of environmental, health and safety regulation might best be achieved through incentive-oriented, rather than a direct federal regulation, approach.

"Such an approach, rather than commanding that specific technologies be applied to achieve the specific standards, allows the industry to choose its own paths to achieving the same end results," he said. And he gave as an example the "bubble approach" which the Environmental Protection Agency had introduced to air pollution, in which a plant can set its own effluent release from each point source as long as the total effluent release complies with a federal standard set for the entire complex.

"One of the important things to recognise regarding this approach to regulation is that it provides new incentives for industry to innovate. It takes some of the repressiveness and uncertainty out of regulation, and relies more on market forces to achieve the desired goals in environmental quality, health and safety."

The need to allow an increased, if not dominant, role for market forces is also emphasised in a report *Energy: The Next Twenty Years,* sponsored by the Ford Foundation and published in Washington last week by Resources for the Future.

"Air pollution control policy should concentrate on providing incentives for making progress toward cleaner air in a way that is cost-effective over time," says the report, produced by a group of academics and industrialists. Attempts to define rigid "safe" exposure levels are both scientifically and administratively unsound, the report recommends moving towards "a different philosophy" of pollution control, deemphasising rigid deadlines and standards, in which market processes determine the details of ways to meet particular environmental goals.

The new shift is also likely to have an effect on the academic environmental science community. "The new climate for environmental regulation makes the need for accurate scientific data even more important than before; in particular there will be a need for better epidemiological data, looking at the real effects both of pollutants and of environmental regulations," says Dr John E Cantlon of Michigan State University, chairman of the National Academy of Sciences' Environmental Studies Board.

"I do not think that all the census work that I have seen indicates that people are willing to give up clean air or clean water. But they may be more willing than before to ask the question of whether the cost-effectiveness level of certain regulations is defensible," says Dr Cantlon.

Finally the environmental movement is beginning to realise that the strategies which it used so successfully in the early 1970s to achieve significant legislative victories may no longer be appropriate for the form of the debate in the 1980s. And that it may be necessary to form new coalitions — particularly with labour or other political groups — if it wants to remain effective.

"One of the weaknesses of the environmental movement is that it has never been able to deal properly with economic issues. But recent moves by the administration on issues such a sythetic fuels mean that the stakes have been raised, and we must deepen both our understanding and our political linkages if we wish to remain effective," says Gail Daneker of Environmentalists for Full Employment.

What effect environmental issues have on next year's presidential election remains to be seen. Certainly many of those who actively supported President Carter earlier in his administration are growing increasingly sceptical. "The one thing worse than having a public figure against you is having a powerful public figure who used to be on your side against you," says David Maselli, referring in particular to the administration's apparent support for a strong Energy Mobilisation Board.

But few see the issue merely in terms of personalities — or of presidential politics. Rather it is a response to an economic and political climate fundamentally different from that which saw the dawning of an "Age of Aquarius" in the late 1960s. With demands for a decreased government role in regulation, and an increased emphasis on market-place economics, moral commitments no longer carry much political capital. □

Next week: health and innovation

ICSU to raise human rights issue at 50 meetings

This summer, a new committee on the 'Safeguard of the Pursuit of Science' of the International Council of Scientific Unions delivered its first report to the ICSU general assembly. The purpose of the committee is to investigate and record cases of scientists unwarrantedly dismissed from their posts or otherwise hampered from pursuing their careers. During its first year's work, the Committee had been apprised of around a dozen such cases, in countries ranging across the whole political spectrum.

This low count, however, does not represent a sudden worldwide liberalization of hitherto oppressive regimes. Rather does it reflect the extremely unobtrusive manner in which the Committee has commenced its activities. For example, not a single case of *berufsverbot* was notified to the Committee. This does not, alas, mean that after all, there are no West German scientists suffering for their allegedly left-wing views. A few days ago, Dr Andreas Dress of Bielefeld University, a leading campaigner against *berufsverbot* in science, told *Nature* that he had not heard of the Committee.

At the 1978 General Assembly of ICSU, when the Committee's founding statement was finally approved (this is a most diplomatically worded document, incidentally, avoiding all such emotive terms as 'human rights'), it was decided that the work of the Committee was an internal affair of ICSU. Accordingly, the statement was never officially issued to the general or scientific press, and only reached *Nature* by informal means almost a year later. Information about the Committee, it was decided, should be disseminated via the usual channels — the national representatives to ICSU (normally national academies of science or their equivalents).

This inevitably suggests a Catch-22 situation. An academy which was actively or passively endorsing the kind of discrimination and repression which it is the Committee's brief to monitor, would hardly be expected to pass on information to its potential victims as to how to obtain a measure of redress. The Committee, however, is less pessimistic. Its Secretary, Professor John Humphrey of the Royal Post-Graduate Medical School, london, told *Nature* that "We start with the premise that the national representatives are no happier than we are that their scientists are being removed from academic life". He admitted, however, that one cannot assume that in such countries the scientific establishment would disseminate news of the Committee very vigorously.

To spread the word more rapidly, therefore, the Committee has decided on a limited publicity campaign. They will display and distribute the founding statement and the forms for reporting abuses at some 50 international scientific meetings in different countries and different disciplines. Visiting scientists, who have not yet heard of the committee through their own national organizations will, it is hoped, be able to publicise the committee when they return home.

The committee's main brief is to investigate and record abuses of a scientist's right to work in his profession. ICSU is a prestigious body, and it is hoped that the moral censure it can impose will have a considerable restraining influence. In the case of highly oppressive or arbitrary regimes, where citizens are likely to disappear without trace, it has been suggested that the committee should play a more active role. Instead of waiting for cases to be reported, the committee could keep a list of all known scientists working in the country, and take as a warning signal any untoward silences or absences from conferences at which they might be expected to appear.

Moreover, in the coming year, the Committee plans to extend its activity to a more general impediment to the free pursuit of science — the vexed question of official secrecy. A working part is to meet to discuss "the losses to science that arise from all kinds of restriction on communication". A total disappearance of the concept of 'classified information' is not envisaged, Professor Humphrey stressed. Rather there would be discussions of how to remove unnecessary restrictions, whether scientists possess any special status, the significance of boycott to the growth of science and so on. It would be, he added "a Pugwash kind of thing, dealing with the impact of restriction of communication of world science, rather than with the rights of scientists."

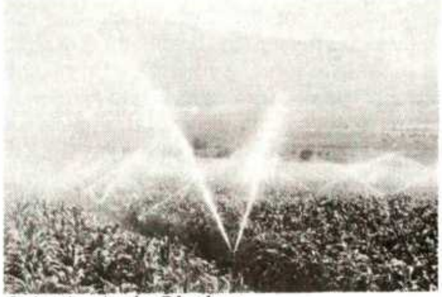
Bulgaria — proud of science on the farm



Irrigation in the Rhodope

"If we say that land is unproductive, it is we who are to blame. It simply means that we have not yet discovered the most rational type of crops for it". So Professor Milko Iordanov, a leading Bulgarian agronomist, told journalists recently. Appropriately, he was speaking at one of the show-pieces of Bulgaria's latest development in agricultural planning and research, the "Georgi Dimitrov agro-industrial complex", in the Rhodope foot-hills.

Agro-industrial complexes, explained Professor Iordanov, are essentially a further stage in the process of amalgamation which, "from 9 September, 1945" onwards, led to the formation of large collectives and cooperatives out of peasant small-holdings. By 1970, he said, it was clear that even cooperatives of 6000 to 12,000 ha still did not permit the "optimal use" of modern technology. Accordingly, the Party adopted as a special aim, the creation of agro-industrial complexes, in which several villages are combined into a single production unit, with its own food-processing plants and agricultural research institutes. Within each complex, said Professor Iordanov, each farm still retains considerable autonomy. The complex, however, is the "general leader", in charge of capital investment and overall policy. Typically, each complex will produce a wide range of crops. At the "George Dimitrov", these change with altitude from orchard fruit, through grapes, tomatoes, hazel nuts and almonds, to potatoes, and finally, sheep grazing.

The research institutes established, in Professor Iordanov's words "for complexes working on a large scale" are subsidised by national funds. Their results and experience are passed on free of charge to any other complexes which are interested although, should experts as well as information be required, it appears that some kind of bilateral contract is established between the complexes, National funding, Professor Iordanov intimated, is given "according to progress", and the research plans are in a considerable extent tied in to the national economic plans. Thus, at the "Georgi Dimitrov", work is going forward not only on specific agricultural problems but also the more general themes of saving energy and material resources. Already, said Professor Iordanov, they have succeeded, by combining a modified American "tilter" cultivator and a Soviet tractor, to obtain the same productivity with a considerable saving of metal.

For the most part, however, research is concentrated on crop investment and the selection of the most productive strains. There is considerable emphasis on "technologies for abroad". Libya already has orchards grown from Bulgarian seeds, and is sending back fruit under a compensation deal. Within Comecon, which has a common research programme on crop selection, the Bulgarian agro-industrial complexes likewise play a major role — indeed, Professor Iordanov admitted — he himself happens to be coordinator for the whole programme.

news in brief

CIA told to reveal university research links: The US Central Intelligence Agency is fighting a court order to reveal the names of universities at which it supported research into the effects of drugs on human behaviour during the late 1960s, under a programme code-named M K-ULTRA. A Washington judge has given the agency until the beginning of next month to disclose the names of the universities involved. Judge Louis Oberdorfer gave this ruling following a Freedom of Information Act suit which had been filed by John Cary Sims and Dr Sidney M Wolfe of the Health Research Group. However at the same time, the judge also suggested that the CIA might be able to argue that releasing the names of the universities would involve a "clearly unwarranted invasion of privacy" of the individual research workers. He also said that the names of the universities themselves might be reclassified as information which it was "in the interest of national defense or foreign policy" not to reveal. John Sims of HRG said last week that the names of a number of the universities involved in the experiments were already known, but that it is important to establish the basic principle. "Information about the MK-ULTRA programme raises the question of what right students and staff have to know about the research being conducted on their campus. Furthermore institutions which have already been identified as working with the CIA have been forced to face publicly the issue of what their relationship with the agency should be."

A spokesman for the agency said last week that it would attempt to persuade the judge that it was still entitled to withhold the names of the universities involved in the programme. It is understood that the director of the CIA, Admiral Stansfield Turner, has already written to all the universities concerned asking if they object to having their names revealed; and that some have replied that they would prefer their involvement with the agency not to become public knowledge.

Thibault named head of reorganised CNRS: Professor Charles Thibault, 60, has been appointed to the newly created post of president of France's reorganised Centre National de la Recherche Scientifique. Thibault, a specialist in reproductive physiology is director of research of INRA, the French agronomy research institute, and has held the chair in the physiology of reproduction at the University of Paris since 1967. He is known for his work on *in vitro* mammalian fertilisation and is a firm advocate of research oriented towards applications. His appointment is expected to accelerate the government's controversial drive to place French research on a more commercially profitable basis.

6000 demonstrate against Scottish nuclear power: SCRAM, the Scottish Campaign to Resist the Atomic Menace, a coalition of 40 anti-nuclear groups, organised one of Edinburgh's largest demonstrations last Saturday as part of a campaign against the development of nuclear power in Scotland. Speakers outlined the dangers of nuclear power generation at each step of the process from mining to waste disposal. Uranium mining, scheduled for Orkney, was singled out for special emphasis because of the large scale environmental disruption that is known to be caused by a process requiring tons of ore to be mined to produce ounces of uranium. In addition the hazards of radon releases associated with mining and toxic chemical wastes associated with the extraction process were emphasised.

Other speakers drew attention to recent controversy surrounding the hazards of low level radiation expected to be associated with the operation of the projected plant at Torness and the drilling for prospective waste disposal sites in northwest Scotland and Ireland was strongly opposed. Local feeling against nuclear dumping runs high and one speaker drew loud applause with the comment: "If it's so safe, why don't they do their drilling in London?" The demonstration attracted trade union representation for the first time in the UK. Mr Mick McGahey, president of the Scottish miners told the rally that nuclear power should not be developed until a comprehensive energy policy is evolved and until strict safety standards could be guaranteed. Coverage of the demonstration was enlivened by the presence of actress Julie Christie (below left) who marched with the Parents Against Tornes group. Christie is opposed to the 15 waste disposal drilling sites, one of which is scheduled for Powys, Wales, where she lives.

"I said commercial — not commercials!"

ESA moves to commercialise Ariane space launcher: The European Space Agency is putting the finishing touches to a French plan to create an industry-controlled corporation to administer Ariane, the European space launcher. Tentatively called 'Ariane-Espace' the new organisation will have control over manufacture and launching of all future spacecraft with government represented only by a minority control. Raymond Orye, head of the Ariane programme explains the move in terms of the usual industry-government relationship. "Once a product is developed it should be handed over to industry for use" says Orye. On the question of industrial control of the corporation Orye explains that the capital risks involved means that "industry needs liberty in order to get maximum return on their investment."

The commercial applications are largely in telecommunications, with 75% of future missions having telecommunications applications. But other exploitable areas are expected to be in Earth resources surveying and in meteorology. At present ESA is in advance of the US in turning over the results of space research to private development. The 11 member states are in broad agreement on the plan and the details on contractual and legal matters, price policy and launch control are being debated in a series of closed Council meetings. The next meeting is scheduled for 10-12 October in Paris.

Traditional Chinese medicine takes new direction: Following a recent document issued by the Party Central Committee on applying the skill and experience of experts, the Beijing (Peking) Health Department has organised its research work in traditional medicines on a new basis. Thirty nine experts have been chosen to take on apprentices or assistants for clinical practice to learn particular skills in treating certain diseases.

In the meantime new books on the clinical practices of individual experts in traditional medicines have been compiled by a team of 40 experts working over the past four years. These include *Liu Fengwu's Experience in Gynaecology, Selection of the Medical Experience of Guan Yubo* (an expert in hepatitis) and *A Collection of Clinical Experience of Zhao Bingnan* (a noted dermatologist) with books on surgery and paediatrics to be issued soon. Work of this sort was started in 1959 but was interrupted by the Cultural Revolution when many academic records were lost and some of the experts were persecuted badly. In 1975, the work was renewed at the bidding of Premier Zhou Enlai.

Asbestos: killer dust, says book

A new book on asbestos claims half a million will die in the UK of asbestos-induced cancer. **Alastair Hay** reports

Five hundred thousand people will die from asbestos-related diseases in the UK in the next forty years according to a book published recently by the British Society for Social Responsibility in Science. In 'Asbestos Killer Dust' the author, Dr Alan Dalton, says that a 1978 US Government Report on asbestos-related cancer deaths makes possible the prediction that a "real epidemic of asbestos related diseases" is about to occur in Britain.

The US report, published by the National Institute of Environmental Health Sciences (NIEHS) estimated that over 2 million American workers will die of cancer as a result of occupational exposure to asbestos. Thus, says Dalton, in Britain — with a population roughly a quarter of that in the US — it can be assumed that asbestos will kill some half million people.

Is the future that grim? It could be, says Dalton, if the recent reports from the US are correct and if Britain does nothing about the current standards regulating asbestos fibre concentrations in the workplace. The standards — based on the number of fibres per millilitre of inhaled air—differ for the various types of asbestos used. Current UK recommendations are 0.2 fibres ml^{-1} for blue (crocidolite) asbestos and 2.0 fibres ml^{-1} for white (chrysotile), brown (amosite) and any other fibre.

According to Dalton the present British standards allow much too high a concentration, and far from being safe present a positive danger to health. Citing a 1976 US National Institute for Occupational Safety and Health (NIOSH) report that there is *no* safe level for asbestos, the author questions the justification for the British standard.

Dalton points out that, in its report, NIOSH recommended a new US standard of 0.1 fibre ml^{-1}—but that even this was chosen because of practical problems in taking accurate measurements of asbestos fibre concentrations. Why then, the author asks, is the British standard for white asbestos 20 times that recommended for the US? And why he questions, does Britain persist with its two-tier standard for blue and white asbestos when NIOSH recommends one standard for both? Mesothelioma, the asbestos-related cancer, Dalton points out, is now quite clearly attributable to exposure to both types of asbestos and not just to the blue form as was originally believed.

The British standards are currently being reviewed by the Advisory Committee on Asbestos of the Health and Safety Executive (HSE), and a report stating the Executive's view on the adequacy of the standard is expected in the next 2-3 months. It has been reported that the committee will recommend that the standard for white asbestos should be halved to 1 fibre ml^{-1}, matching Sweden's limits; that the limit for brown asbestos should be reduced to 0.5 fibre ml^{-1}; and that blue asbestos should be banned, with the standard for its removal remaining at the present 0.2 fibres ml^{-1}.

It is quite clear, however, that the original study at the Turner and Newall factory in Rochdale in 1966 which laid the basis for the British standard was flawed. The number of asbestos-related health problems was considerably underestimated. Only workers who had completed 10 years service and were still in the company's employ were included in the study; those who had left the factory were not followed up. In addition the clinical test used to assess the effect of accumulated asbestos exposure has been criticised as being too stringent.

The test measures the prevalence of crepitations (abnormal sounds in the lung during exhalation and inhalation) and it has been suggested that this test might only identify more serious asbestos injury and miss cases with minor damage. Furthermore, there are indications that the dose/response data from the Turner study may in fact be wrong, as the dust level was actually higher than originally reported.

Although there is no official comment from UK Regulatory Authorities on the 1978 NIEHS report for asbestos related cancer deaths, criticisms have been made about it in private. For example, it is known that the HSE feels that figures for deaths in the US cannot be applied to the UK. Scientists at the HSE are known to have doubts about the validity of the assumption in the NIEHS report that the "relative risk" of developing cancer is constant throughout life. Furthermore assuming the most conservative estimate of risk in the NIEHS report it can be calculated that at least 5000 deaths from mesothelioma should be occurring annually. In 1976, however, the US figure was 1000 deaths.

Even though the HSE feel that Dalton has considerably over-estimated the dangers, the Executive does admit that mesothelioma deaths present a real problem. Figures collected by HSE's Employment Medical Advisory Service show that deaths from mesothelioma have risen inexorably since 1968. EMAS figures for 1968, 1972, 1974, 1977 are 154, 208, 230 and 323 deaths respectively. An HSE spokesman pointed out that the mesotheliomas may not have been due to asbestos; but he did confess that it was almost certain that they were. □

Desai's difficulties with AT

Alternative technology is no simple panacea for India writes **Anil Agarwal**

WITH the emergence of the Janata government in 1977, considerable hopes were raised both within the country and outside, that India would become a major Third World country actively using and supporting appropriate technology (AT). The need for AT was mentioned in the election manifesto of the Janata Party and, in his very first broadcast to the nation, Prime Minister Morarji Desai, had emphasised that "the big city, the big machine and big science have their place. But they cannot claim a prescriptive right to preference and dominance. We have to make the village the centre of our economic progress."

The industrial policy announced by the Janata government in December 1977 also recognised the importance of reducing unemployment and rural-urban disparities in India's future industrialisation programmes. Although India is today the tenth largest industrial producer in the world, the total number of its unemployed is almost equal to the total number of those employed by all its organised mills, factories and services. Mr George Fernandes, the Janata Industries Minister, therefore, declared that AT "will henceforth be an integral part of policy and government will ensure that this important area gets adequate attention." The Janata government, he stated, "will not favour large scale industry merely for demonstration of sophisticated skills or as monuments of foreign technology. The main thrust of the new industrial policy will be on effective promotion of cottage and small industries widely dispersed in rural areas and small towns."

AT, thus, appeared to be in early 1978 not only a sensible option for India, but also one of enjoying great support. However, over the months the initial resolve of the Janata government in favour of small-scale labour-intensive rural-oriented AT was weakened. This was, to a great extent, because of the myriad inter-party factional tensions, which virtually sapped the very will of the government to govern, but partly also because of the strong opposition from scientific and industrial establishments.

The Janata government's advocacy of AT was unfortunately accompanied by a barrage of criticism of the country's past scientific and technological activity. The critics argued that the country had not adequately benefited from its large investments in R&D institutions and that

0028-0836/79/380172-03$01.00

Spinning polyester: more jobs, but does it increase dependence?

the direction of past R&D activity was too urban and big industry-oriented. Eighty per cent of Indians, they argued, live in the villages yet very few technologies have been developed to meet their needs.

This criticism obviously drew counter-criticism. Professor M.G.K. Menon, the former Chairman of the Electronics Commission and the current Director-General of the Council of Scientific and Industrial Research (CSIR), for instance, strongly argued that although research can be done to find new ways of using agricultural and animals wastes in rural areas, and so on, it is nonetheless wrong to criticise the CSIR and its institutions for neglecting this kind of research because it was not in their initial charter to do so. Secondly, some scientists even argued that the government's advocacy of rural development, appropriate technology — and, in fact, even its efforts to reorganise bodies like the CSIR (See *Nature*, vol) — betrayed an "anti-science and anti-technology belief". Professor A.K.N. Reddy of the Indian Institute of Science at Bangalore, a well-known advocate of AT, alleged in an article in an Indian economic journal that there is a "widespread suspicion that the present government, in its over-riding concern for rural problems, believes that these problems can be solved *without* science and technology." Dr Reddy stated his own belief that the generation of AT is "rarely a trivial affair — it invariably requires subtle analysis, innovative experimentation and design, and sophisticated scientific and engineering thinking." According to Reddy, developing countries interested in AT must develop their own indigenous sophisticated scientific skills and that they must conduct basic as well as applied research. To take one instance, basic studies of methanogenic bacteria can greatly contribute to the development of biogas systems.

Some senior Indian scientists and science policy experts also denounced AT as a concept that is largely being promoted by those western lobbies who want to belittle India's past efforts towards technological self-reliance and keep Third World countries permanently dependent and backward. In what was an obvious reference to developments in India, Mr Ashok Parthasarathi, the current Secretary to the Electronics Commission and former special assistant on science and technology to Mrs Gandhi, told a seminar on the UN Conference on Science and Technology for Development (UNCSTD) held in Sweden in late 1978, that there is a strong body of opinion amongst the "nationalist segment in most Third World countries" that regards AT "as a diversionary tactic on the part of the North — diversionary in the sense that it seeks to redirect a significant part of the scientific and technological (S&T) capacity of Third World countries towards the development of these new 'rural-oriented', 'appropriate' technologies, leaving the main muscle of industrial power — the petrochemical complexes, the steel plants, the railways, the power plants — in the hands of transnational companies."

Indian scientists who share this argument point out that even if a Third World country were to make rural modernisation and agricultural development the prime goals of its development strategy, it would still need several sophisticated industrial products like cement, chemical fertilisers, pesticides, iron and steel, trucks, railway systems and electricity to make its strategy work. The technology required to produce all these products is today dominated by western multinational corporations.

The critics further challenge the value of diverting large scientific efforts towards the development of rural-oriented AT by pointing out the strong evidence that has emerged in recent years that what is known as AT, in a highly stratified society like that of India, tends to benefit the rural rich and not the rural poor. A prime AT like the development of biogas plants has been found to have benefitted only those landowners who possess the money and cattle to buy and operate such plants. Rural modernisation and eradication of poverty, the critics argue, require a political will for structural transformation within society. So, it is claimed, if a Third World country like India were to pay too much attention to AT it would not only fail to improve the lot of its rural poor but also, in the process, become more dependent for its modern technological needs on foreign multinational corporations.

Indian supporters of AT like Mr M.M. Hoda of the Appropriate Technology Development Association in Lucknow protest that the proponents of modern western technologies, while raising fears of a strengthening of the rural elite, are conveniently forgetting that their own technological strategy will lead to the strengthening of an already powerful urban-industrial elite. And that this elite will equally oppose any structural transformation that may be required in the long run to eradicate poverty. The argument that the Janata leaders are "anti-science" appears to reflect the elitist character of the scientific community itself. It is indeed not rare to hear an Indian scientist calling the Janata leaders a pack of 'desi' (native) people, largely because they do not possess the finesse that earlier leaders like Mr Nehru and Mrs Gandhi acquired from their western educations.

AT-protagonist Reddy, however, does criticise western organisations and aid-agencies for their excessive advocacy of AT. By giving the impression that AT is something mainly suitable for the Third World and by doing precious little to develop 'appropriate' technologies for use in developed countries themselves, Reddy argues that western organisations are not just being extremely patronising but are also producing very counter-productive results with their advocacy. Their enthusiasm, he claims, has created such a strong backlash to the concept of AT in India that even Indians are now finding it difficult to advocate it.

"What India needs is both large and small-scale technologies," explained an anti-AT senior policy-maker to me, a few months before Mr Desai's government fell. "We should not be asking organisations like CSIR to redirect their efforts towards rural-oriented AT but instead be asking them to step up their research efforts to develop both small-scale rural-oriented technologies as well as those technologies that are required by modern large-scale industry." "I think," he proudly claimed, "that we have now succeeded in educating the new Janata leaders, including the Prime Minister."

That a Third World country like India needs a mix of technologies was pointed out even in the Indian national paper to UNCSTD. The paper explains that while the broad criteria for the appropriateness of technologies must be defined by a nation's development objectives (like meeting basic needs, employment-generation, self-reliance and environmental protection), the implied productivity *versus* employment problems can be resolved only by adopting a balanced mix of capital-intensive and labour-intensive technologies, of centralised and decentralised production, and of large-scale and small-scale units.

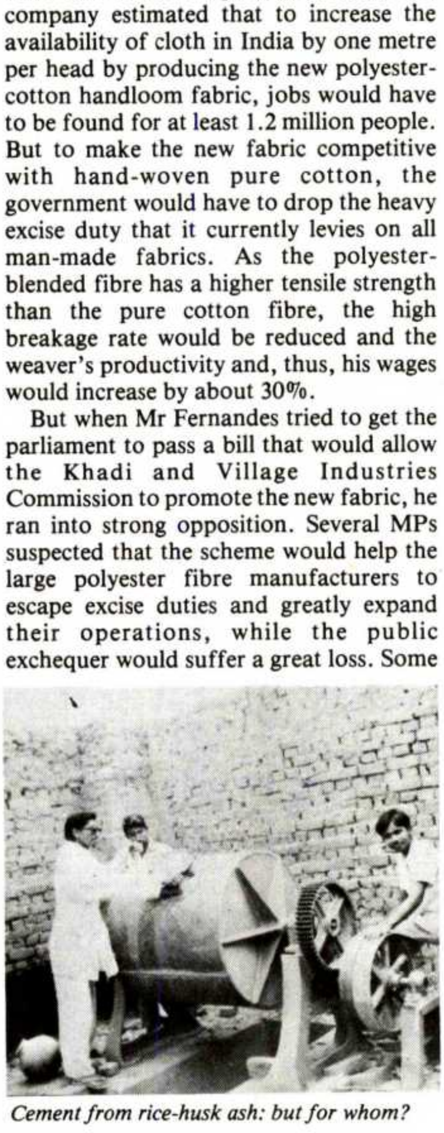
But what exactly is it that the Janata government has tried to do in the home of AT, apart of course from speeches by Prime Minister Desai and other Janata leaders that Indian scientific research needs a different direction? The clear answer is: 'not very much'. The main attempt to go small and introduce the concept of appropriateness in technology choice was restricted to the — albeit important —industrial sector, and here too the Janata government merely tried to put more teeth into a policy that all former Indian governments have advocated since the mid-1950s to protect and promote small-scale industry. The Ministry of Industries increased the number of items exclusively reserved for production in the small-scale sector from 180 — under Mrs Gandhi's government — to over 500. And to help promote the development of small industries in neglected backward areas, it launched a scheme to set up an industry centre in each district of the country. The centres will provide small entrepreneurs with all the services and support they require under one roof, including economic investigations of a district's raw material and other resources, supply of machinery and equipment, provision of raw materials, arrangement of credit facilities, quality control and research. The scheme, which started in May 1978, has had teething difficulties, but 223 centres had been sanctioned by end of 1978.

In certain industries like cement, matchsticks, soap and textile manufacture, which can be operated on a small scale, Mr Fernandes — the Minister for Industry — strongly supported efforts to make small-scale ventures succeed. For instance, his ministry provided a 50% rebate in excise duty for cement produced from mini-cement plants (with a capacity less than 200 tonnes per day). Dr S. Chopra, Director-General of the Cement Research Institute, which has developed 20 tonne per day capacity plants, estimates that mini-cement plants should be producing about 10% of India's cement within the next five years. Mr Fernandes also strongly advocated the manufacture of cement from rice husk ash, though some scientists feel this was premature, as there are very few such plants in existence in India and the quality of their product still needs to be standardised.

Under Mr Fernandes, the Ministry of Industry also asked those large industries, many of which are subsidiaries of western multinationals, which produce such mass consumer goods as soap and matchsticks, to phase out production within three years and allot it to continue in labour-intensive cottage and small-scale units. The Minister pointed out that nearly 70% of India's matchsticks were being made by cottage industries, which employed 450,000 people. But the Western India Match Company, a subsidiary of a Swedish company, which makes the remaining 30%, was employing only 15,000 workers. Mr Charan Singh, who was Finance Minister in Mr Desai's government and is a fervent advocate of rural cottage industries, tried to force WIMCO out of the market by increasing excise duties on all machine-made matches and halving that on hand-made matches.

In the textile industry too, the Janata government pushed the existing policy to support handlooms further, by forbidding further expansion in the weaving capacity of textile mills. About ten million people are already employed in the handloom textile sector, which makes it the largest employer in India outside agriculture. But unfortunately most of them are only part-time workers and their wages are abysmal. Mr Fernandes tried to introduce a new technology to upgrade this industry and thus increase the productivity of handloom weavers and their wages. But he met with strong resistance from his own party. The Industry Minister tried to promote a technological breakthrough that allowed cotton-blended man-made fibres to be both hand-spun and hand-woven for the first time. The breakthrough had been achieved by a private Indian company which manufactures polyester fibres. The company estimated that to increase the availability of cloth in India by one metre per head by producing the new polyester-cotton handloom fabric, jobs would have to be found for at least 1.2 million people. But to make the new fabric competitive with hand-woven pure cotton, the government would have to drop the heavy excise duty that it currently levies on all man-made fabrics. As the polyester-blended fibre has a higher tensile strength than the pure cotton fibre, the high breakage rate would be reduced and the weaver's productivity and, thus, his wages would increase by about 30%.

But when Mr Fernandes tried to get the parliament to pass a bill that would allow the Khadi and Village Industries Commission to promote the new fabric, he ran into strong opposition. Several MPs suspected that the scheme would help the large polyester fibre manufacturers to escape excise duties and greatly expand their operations, while the public exchequer would suffer a great loss. Some people also feared that the new fabric could drive those traditional weavers out of jobs who were not able to organise themselves sufficiently to benefit from the new technology. The new fabric could result in more unemployment. Mr Fernandes failed to get parliament's support.



Cement from rice-husk ash: but for whom?

However, an official in the Planning Commission who has long been a lone advocate of AT in official circles, pointed out that cement, for instance, even if it is produced on a mini-cement plant, will remain an inappropriate product for building houses in India as it is beyond the purchasing power of the majority of the country's population. Only a policy that promotes housing technologies which reduce the use of cement and increase the use of traditional building materials such as mud can be described as a policy for AT in the housing sector. But big ostentatious houses, built with a wasteful use of cement, are the order of the day amongst the Indian elite and such an approach to AT would require a very strong political will, something that the Janata government failed to display.

Meanwhile, however, Indian planners are certainly learning much to their chagrin that domestic technological capability can be a double-edged weapon. It can be used to subvert national objectives, just as much it can be used to serve them. The Planning Commission in 1977 had refused the State Government of Punjab permission to import combine harvesters. It had argued against these machines on the grounds of massive unemployment within the country. But the Punjab had created such a huge demand for labour that farmers within the region face crippling shortages of labour, particularly during periods of peak labour requirements. After the central government turned it down, the Punjab government approached the Punjab Tractors Limited (PTL) in Chandigarh, which it had helped to set up, to manufacture these combine harvesters. This company had been set up by an extremely enterprising group of former R&D engineers from the Central Mechanical Engineering Research Institute (a unit of the CSIR) to manufacture a small tractor that they themselves had designed. Production of the tractor started after considerable delay and opposition from those interest groups which wanted to collaborate with foreign companies. The efforts of this group for technological self-reliance have thus been widely praised and discussed. But now the PTL management cannot refuse to design and develop combine harvesters for the government of the state in which it is based even though it may not be happy to do so. The first prototype of an indigenously designed combine harvester is expected to be ready soon. Domestic technological capability thus would have served the Punjab government's purpose but subverted the Planning Commission's objectives. Now how does one control such a situation? □

UNCSTD: now we need action

Arnoldo K Ventura, Technical Director of the Scientific Research Council of Jamaica, counts UNCSTD 'a stitch in time'

After five preparatory conferences, several national, regional, and specialised meetings, UNCSTD begrudgingly approved a programme intended to tackle worldwide underdevelopment. But, because of the complexities of over-development and under-development, and the fact that the precise relationship of science and technology to development is still being unraveled, the conference was anchored on presumptions based on superficial observations and good intentions. Consequently, the resulting programme remains essentially a series of imprecise generalities which now beg for more precision and implementation.

The *ad hoc* mixture of politicians, diplomats, bureaucrats, and a few scientists, many of whom were attending the 'circuit' for the first time, or who were vaguely familiar with the nuances of the Conference, did not help the UNCSTD deliberations, while many of the few oldtimers in the UNCSTD extravaganza had already formed hardened opinions. Consequently, in spite of the fact that no legal codes were being considered, the debates were often long and tedious.

The debates lacked specificity, and it was clear that neither the developed nor the developing countries had a firm grasp on the systems, steps, or components of science and technology which are necessary to redress the problems of mal-development. Very little note was taken of the fact that while many studies have shown a strong relationship between rising industrialisation and the ferment of scientific technology, few categorically outlined comprehensive strategies for the resolution of underdevelopment based on the unique experiences of Europe, US, Japan or recently industrialised states.

As a matter of fact, the pivotal components of the science and technology process which have lead to the successes of the developed countries are still being determined. Consequently, the UNCSTD debate was replete with emotion and defensive rhetoric, rather than with compromise flowing from a framework of scientific facts or well-documented experiences. The "programme of action" used as the base document for negotiations was not action-oriented, as a result of the paucity of concrete information regarding the proper way to deploy science and technology to promote a balanced development within under-developed countries.

Although it is generally accepted that a decent level of indigenous technological competence is vitally necessary for this process to take place, the basic infrastructure necessary to provide this capacity in light of different concepts of development and differing national resource endowments, is still not fully understood. Furthermore with limited technological capacities in many developing countries and with many countries still not sure of the type of investment or sacrifice needed to attain increased capabilities, the developed countries during UNCSTD tended to view the problem of underdevelopment in terms of what can, instead of what should, be done.

The ill-effects of some modern technologies on society, on culture, and on the environment have further confused the question of science and technology for development, thereby raising doubts about the transfer of the most modern technology for the amelioration of poverty. This type of confusion of the issues often lead to extreme positions, especially among delegates exposed to them for the first time. This engendered superfluous verbiage and a train of stalling manoeuvres. Nevertheless, in general, the debates have served to emphasise the fundamental nature of the problem and may bring solutions nearer.

Against this background, it was unfortunate tht some specialised agencies decided unabashedly to use UNCSTD as an opportunity to expand their power base. This distraction from the main thrust of the Conference underscores the dilemma of poor countries, as often institutional politics looms to obliterate the pressing need to harmonize against the ravages of underdevelopment. This suggests the need for closer examination of the UN agencies and their contribution to the relief of human suffering.

Although much can be said about the imperfections of UNCSTD, its signal importance should not be overlooked. Apart from generating an increased awareness of the indispensability of science and technology to development among the developing world — the elaborate preparatory process for the Conference achieved that — the event itself brought together national decision makers and functionaries from the scientific communities to discuss concepts which are of vital interest to both. Such ventilation of the issues from different perspectives very seldom takes place at the local or national levels, and hopefully this may be the beginning of operational links between international political and the scientific circles, which may provide a clearer picture of the problems and bring us closer to collective solutions. UNCSTD gave the opportunity also for socially concerned scientists, from countries at different stages of development, to share experiences.

It is interesting to see how the voluntary contribution of some $250 million for 1980 and 1981, earmarked for the promotion of science and technology, will be utilised in the underdeveloped countries, granted the inadequate technological capacities in these areas, and the fact that the amount is paltry compared to the magnitude of the world's problems. It is clear that the major contributors will be tempted to control the expenditure of these funds, either to ensure that these allocations are used to establish a viable scientific and technological infrastructure or surreptitiously to ensure that these funds are not used to create undue competition for their local industries. It will be interesting to see how Third World scientists and technologists respond to the disbursement of these resources. UNCSTD, undoubtedly, will force some reaction from the scientific and technological communities of the Third World. Their response in turn will surely condition the attitude of their counterparts in the industrialised states in future.

There is also some hope for change — as the Conference has engendered more solidarity within the Group of 77, while there appear to be more areas of contradiction and differences arising among the ranks of the rich as they struggle to contain the poor countries in the status quo. Varying degrees of rivalry and contrasting views of the future have begun to prick the national consciences within the developed states. Further, the smaller and more susceptible rich countries find their interest merging closer to those of the underdeveloped states. This type of realism opens up avenues of salvation for mankind.

UNCSTD, if only for its size, has stirred the attention of the world. It has prompted new insights into the causes of the glaring disparities plaguing mankind. It has stimulated the closer examination of the relationship between science, technology, and societies, and it has bared fundamental questions concerning the future of mankind and the extent to which the global and local environment may be manipulated with impunity. New philosophies are surfacing as a consequence.

A realistic alternative to the arms race has been forwarded as scientists and technologists are being called upon to attack poverty instead of the human race. The concept of science being the common heritage of man is being extended to technology, which signifies the emergence of a new morality within the brotherhood of man. These are fundamental concepts which for expression will require basic changes in the psyche of the human race, and consequently, will be long in reaching maturity or practical fulfillment, but nevertheless they were being voiced by responsible delegates. Probably, UNCSTD is a 'stitch in time' which may save the international community from continuing along the path of global maldevelopment resulting from the misuse of the power of science and technology, and the espousing of bankrupt economic philosophies devoid of strong social probity. ☐

Accounts of East European science are reliable

SIR, — Dr Lorch's attack on Vera Rich (13 September, page 98) is not only graceless: it is also futile. As many an obfuscating party bureaucrat knows to his chagrin, she is a tough and determined person who thrives on reckless abuse and has an uncanny facility for discovering awkward truths behind the glossy facades of official science. In other words, she brings to the readers of *Nature* the best-informed and most reliable account of science in Eastern Europe and the Soviet Union that is publicly available in the Free World. In so doing, Ms Rich complements the correspondingly unsycophantic reports of Colin Norman and David Dickson from Washington, and the sober dispatches that you have recently been publishing from various countries in the Third World. Good work; keep it up.

For it is not by enthusiasm for intergovernmental research projects, nor by the exchange of vacuous academic courtesies between scientists of rival nations, nor by cheerful splurges about marvellous work being done in this or that country, that the pursuit of science will be safeguarded. The fundamental factor for the health of the world scientific community is solidarity in protecting the human rights of scientists of all countries.

I believe that most of my colleagues with recent first-hand knowledge of the state of science in many countries of the Socialist *bloc* would agree that the situation is very largely as Ms Rich describes it, and that this continues to be a matter of the gravest concern for us all. The information that you thus make public in *Nature* is not only essential for those who would combat such evils: it is, by its very publication, of immense influence.

Yours faithfully,

JOHN ZIMAN

University of Bristol, UK

Doctor disappears in Afghanistan

SIR, — I am writing on behalf of the staff of this department, to bring to the attention of our scientific and medical colleagues, difficulties we are having in communicating with a former colleague in the Faculty of Medicine, University of Kabul, Afghanistan.

He is Dr Z. Razban, a medically qualified member of the staff of the Department of Medical Biochemistry in that university. He spent two years with us on a WHO Fellowship to gain experience in teaching biochemistry to medical students and also on research in immunological aspects of protein-calorie malnutrition. When he left us in January 1977, he was well trained in a variety of immunological techniques and had been awarded an MSc based on his research on "Acute phase proteins in children with protein calorie malnutrition" which was also published under this title (Razban *et al. J. Trop. Med. & Hyg.* **78**, 264-266 (1975)).

At that time we understand he was the only doctor in Afghanistan trained in immunology, and on his return he intended to set up an immunological service and to train other doctors and technicians in these techniques, as well as continuing his research and teaching. In order for him to do this successfully it was essential for him to maintain contact with us, and we find it disturbing that for reasons we are unable to discover, this contact has not been maintained. We are certain that Dr Razban would himself have continued to remain in contact with us, and can only assume that he is prevented from doing so by the authorities in Afghanistan.

Yours faithfully,

D.S. JACKSON

University of Manchester, UK

Tumour virus DNA: hazards no longer speculative

SIR, — The critical response (9 Aug, page 444) by Drs Rowe and Martin to the editorial (7 June, page 461) which called on the US Congress to enact recombinant DNA legislation, appears itself to be somewhat misleading.

While it may have been technically incorrect for the editorial to imply that it was unanticipated by tumour virologists that DNA from tumour viruses can cause tumours, it remains true that no one could have known prior to the Rowe-Martin risk assessment experiments (*Science* **203**, 883 and 887; 1979; Israel et al, *Science* in the press) that tumour virus DNA which has been cleaved with restriction enzymes and spliced into plasmids or lambda phage genomes would retain tumorigenicity.

The importance of this finding is the following: up until now opponents of strict recombinant DNA guidelines and legislation have portrayed fears that an aetiological agent could escape the laboratory in a novel biological form as "purely speculative." However, bacterial plasmids and lambda particles do not customarily carry agents of animal carcinogenesis into the ecological niches occupied by their bacterial hosts. It has now been shown by Rowe, Martin and their coworkers that it is a fairly routine matter to construct plasmids and lambda particles with just such a capability. The fact that these splice products are less effective than ordinary polyoma viruses in promoting tumours in the normal hosts of polyoma is irrelevant: the bacterial route for the dissemination and variation of tumorigenic DNA is a qualitatively new one.

The unlikelihood that the Rowe-Martin experiments released any novel tumorigenic vector into the environment is largely due to the fact that these studies were carried out under P4-EK2 containment protocols. However, under the newly revised NIH Guidelines (*Federal Register*, January 15, 1979) such tumour virus splicing experiments can now be carried out under P3-EK1 or P2-EK2 protocols.

It should be noted that the efficacies of both the biological safety cabinets used in P2 and P3 experiments, and of the only approved EK2 host, *E coli* χ 1776, have been recently called into question (*Nature*, 29 March, page 384; S. Levy, technical report to NIH under risk assessment contract; R. Curtiss III, letter to NIH, May 11, 1979).

Since the hazards of releasing into the ecosystem known aetiological agents in new biological forms can no longer be considered speculative, it should now be unacceptable to denigrate efforts by the NIH Recombinant DNA Advisory Committee, and by the public through its unions and government, to tighten containment through guidelines and legislation that extend to industrial as well as academic laboratories.

Yours faithfully,

STUART A. NEWMAN

New York Medical College, New York

Meeting on carcinogen testing is open

SIR, — In the 23 August issue (page 623) Alastair Hay wrote a short article "Press banned from conference" in which he discussed the status of press invitations to a meeting to evaluate short-term in vitro tests for carcinogenicity. The meeting is open to the public as are all such US Government sponsored meetings, and contrary to his headline and article the press has been neither banned, excluded nor specifically invited.

Investigators of the international programme for the evaluation of short-term tests for carcinogenicity will meet in October to present and discuss their results for testing 42 coded chemical samples. Results from a total of 68 assay system investigators will be presented. The meeting will not be comprised of formal presentations but rather of concurrent work groups. During the first part of the meeting five separate work groups will meet to discuss the raw data from similar bioassays. During the second part of the meeting the participants will be grouped into work groups to evaluate the cumulative test data on individual chemicals. Both phases of the meeting will require tedious analysis of large volumes of raw data and review of details of experimental protocols, neither of which is usually of interest either to the scientific community at large or to the press.

The coordinating committee fully recognise the importance of this study as well as the preparation of a final report for general distribution. It was this recognition that led to the decision to use two different mechanisms to bring this final report to the attention of the scientific and regulatory communities and the public.

Firstly a full account of the study will be published including the section on chemicals reviewed and carcinogenicity data on each chemical, results from individual investigators and an overall summary and evaluation. Secondly, a public information meeting has been planned for 3 December at the National Institutes for Health, Bethesda, to present and discuss the complete results of this study. It is the feeling of the coordinating committee that the six weeks between the October and December meetings will be necessary to make a comprehensive and meaningful evaluation.

It is regrettable that there has been such a misunderstanding concerning press participation at the two meetings planned to bring the international trial to completion.

Yours faithfully,

THE COORDINATING COMMITTEE

J ASHBY

B A BRIDGES P BROOKES

I F H PURCHASE T SUGIMURA

● *Alastair Hay writes: My experience, and that of other British science journalists, was that we applied to attend the meeting — only to be told that the presence of journalists might inhibit balanced scientific discussion. I subsequently had a letter from one of the organisers, confirming that no journalist was to be invited. If I misunderstood the committee's real intentions, then I apologise.*

news and views

Arctic animals and climatic changes

from Robert M. May

THERE is a tendency in much of the ecological literature to think of environmental change as taking place either on a very long, or a very short, time scale. Thus attention is given to the way populations, or even entire communities, respond to the major changes in climate that occur on geological time scales. At the other extreme, many studies concentrate on the influence short, year-to-year climatic fluctuations can have on the dynamics of populations (for example, in fish recruitment or locust outbreak). In a recent working paper of the Interim Committee on Marine Mammals of the International Union for the Conservation of Nature (ICMM/1/WP1), Laws, Gordon Clark and Dunbar note that there appear to be significant changes in climate on many intermediate time scales. They emphasise that such systematic environmental changes, particularly in the time range from around a decade to a century, raise important questions for conservation and resource management; these questions have conventionally received little attention.

Most people are familiar with the long sequence of alternations between glacial and interglacial epochs of climate, with a period of about 100,000 years, that has characterised the past million years or so. Mid-latitude temperatures today are 5°-8°C warmer, and sea levels 80 - 100 metres higher, than those prevailing during extreme glacial stages (the most recent being the Würm or Wisconsin glacial maximum, about 18,000 years ago). The World Meterorological Organization and others have used a variety of palaeoclimatic indicators to show that, following recovery from the Wisconsin ice age, the global climate has exhibited systematic fluctuations (albeit within narrower limits than those characterising the ice-age epoch), with expansions and retreats of polar ice and mountain glaciers at intervals of about 2,000-3,000 years. Nested within this is finer-scale structure: stratigraphy and pollen from Swiss and other glaciers shows five cycles of glacial advance and retreat over the past 3,000 years, with temperature minima around 1400-1300 BC, 900-300 BC, AD 400-750, AD 1200-1300 and AD 1600-1850. The 'Little Ice Age' of 1600-1850 is a well-documented historical event, during which temperatures in northern Europe were 1° or 2°C lower than today and stormy conditions prevailed in the North Atlantic. Conversely, some of the intervening climates have been better than today; during the 'Little Optimum' of the 10th, 11th and 12th centuries (with a peak around AD 1080-1180) a Viking colony flourished in Greenland and wine was produced in England.

Laws *et al.* point out that "Within the lifetime of people at present in their 60's there has been a climatic cycle that has affected the economy of a number of countries." This cycle began on an upswing to warmer conditions about 1915, reached a peak in the early 1940s, and returned to colder conditions over the past 35 years or so. This downswing is probably still continuing. Older people's memories of the golden summers of their youth have a measure of objective reality. During this 60-year interval, temperatures in the regions of the West Greenland current, in Baffin Bay, in the waters of Iceland, and around Spitzbergen have fluctuated over many degrees in the atmosphere, and some 2°C in the hydrosphere. In the Antarctic, all stations with long records show trends in mean annual temperature over the past 75 years (1900-1975), of total magnitude 0.3°C at South Georgia, 0.7°C at McMurdo, 1.1°C at Laurie Island in the South Orkneys, and about 1.9°C for the Antarctic Peninsula (British Antarctic Survey Annual Report, 1976-1977). In South Georgia there has been a steady 33% increase in rainfall since 1906, while in the Scotia Sea there have been marked changes in the circulation (BAS Annual Report, 1975-1976). These temperature changes of a degree or two may sound modest, but they represent the transport of enormous quantities of heat.

Many of the grander patterns of human history can be reinterpreted in terms of the systematic climatic fluctuations of the past 3,000 years (see, for example, Ladurie, *Times of Feast, Times of Famine,* Allen and Unwin, 1976). There have undoubtedly also been marked effects on many animal populations, especially in the sea. Unfortunately, little direct evidence is available. One exception is the demonstration by Thoradotir (in *Polar Oceans,* ed. Dunbar, Arctic Institute of North America, 1977) that the primary production north of Iceland decreased greatly by a factor of at least 2 or 3, between about 1965 and 1975, presumably in response to a cooling of the water and the southward extension of the limit of sea ice. Another important study is by Vibe (*Meddr Grønland* **170,** 1; 1967), who uses bone material uncovered by archaeologists in their excavations of Eskimo and Norse settlements in Greenland, and accounts of sales to Greenlanders of rifles and other equipment, to get an idea of the way climatic fluctuations have influenced the population density and geographical distribution of animals in and around Greenland. Vibe considers ringed seals, harp seals, narwhals and white whales, polar bears, walrus, Greenland whale (or bowhead, *Balaena mysticetus*), blue and white arctic fox, ptarmigan, eider, reindeer, musk ox and cod. He broadly distinguishes three periods since the early 19th century. In the "drift-ice stagnation stage" (1810-1960) the climate of northern West Greenland is relatively cold, dry and stable. This climate is favourable for reindeer in central and northern West Greenland, and the population increases; populations of sea mammals and sea birds concentrate at central West Greenland. The drift-ice is also relatively stable throughout the winter off North-East Greenland, where the climate is favourable for the reindeer and the musk ox, whose populations flourish. In the "drift-ice pulsation stage" (1860-1910) the ice of the Arctic Ocean drifts into the Atlantic in larger amounts than before, and the climate becomes warmer with much precipitation and with great fluctuations. The populations of sea mammals and sea birds decrease in central West Greenland, and the wet winters are unfavourable for reindeer and musk ox, whose populations decline. In the "drift-ice melting stage" (1910-1960) the drift-ice of the East Greenland Current decreases, and the climate is relatively warm with some precipitation. Cod multiply in Greenlandic waters, and populations of sea mammals and sea birds increase in northern West Greenland and in East Greenland. The reindeer populations of West Greenland have ample summer grazing, but the winter

0028-0836/79/380177-02$01.00

pastures are often covered by snow and ice, so the population fluctuates. Of particular interest is Vibe's comment that, "Until recently, like all other Arctic animals the Greenland Whale was very numerous during certain periods and less numerous during others. Its distribution and mass occurrence was determined more by movements in the drift-ice than by persecution from Eskimo and European whalers."

These climatic cycles, and the associated changes in the distribution and abundance of animals, have had major effects on the economies of Greenland and Iceland. The gist of Vibe's analysis is that, over the past 60 years, in West Greenland the whole ecosystem moved north with the warming and south again with the cooling, so that a seal-hunting economy was replaced by a cod-fishing economy, the latter now being in some jeopardy. Off Iceland, the herring fishery disappeared northward, and later reappeared in northern coastal waters. Similar events, also involving the Atlantic cod, occurred around Spitzbergen. Discussing long-term trends in the climate, Cushing (*Science and the Fisheries*, Arnold,1977) points to the alternation between the Norwegian herring fishery and that off the Bohuslan coast of Sweden, which has persisted since the Middle Ages, as being associated with the well-documented 100-year periodicity in the wind system of the northern hemisphere. There may be a similar 100-year periodicity in the fishery for the Japanese sardine.

In short, many different lines of evidence and inference suggest that systematic changes in climate take place on different time scales, and with various amplitudes. Laws *et al.* are clearly correct in arguing that "The shorter cycles, terms of a decade and up to half a century cannot be reasonably neglected for purposes of resource management." Two intertwined problems emerge: to achieve skill in forecasting such climatic changes; and to convince resources managers to include these factors in their deliberations. ☐

First discovery of fossil tree shrews

from R.D. Martin

THE recent identification in Indian Sivalik Miocene deposits of fossil material exhibiting clear affinities with modern tree shrews reported by Kaul *et al.* and Vasishat and Chopra in this issue of *Nature* (pages 213 and 214) fills a major gap in our understanding of this unusual group of mammals. The tree shrews achieved prominence some 50 years ago when Le Gros Clark pointed out in a series of papers a number of characters (notably in the morphology of the skull, brain and reproductive system) suggestive of an evolutionary relationship to the order Primates (*Proc.Zool.Soc.,Lond.* **44**, 461: 1924; *ibid* **44**, 1053; 1924; *ibid* **45**, 559; 1925; *ibid* **46**, 1179; 1926). The transfer of the tree shrews (family Tupaiidae) from the order Insectivora to the order Primates was given an international seal of approval by Simpson in his influential classification of the mammals in 1945 (*Bull. Am. Mus. Nat. Hist.* **85**, 1; 1945), and numerous papers followed on the supposed primate-like features of these semi-arboreal, South-East Asian mammals. However, since the 1960s a growing number of investigators have rejected the concept of a specific phylogenetic relationship between tree shrews and primates, and one of the most recent, authoritative primate classifications excludes the tree shrews altogether (Simons *Primate Evolution: An Introduction to Man's Place in Nature,* Macmillan, New York; 1972).

It is probably true to say that the modern consensus is that tree shrews are not related to primates after all. This view is partly based on additional evidence regarding cranial, dental and cerebral morphology along with reproductive characteristics and biochemical aspects. However, reassessment of the methodology used for reconstructing phylogenetic relationships has had a far more fundamental and far-reaching influence on the elucidation of primate evolution. It is, in fact, still true that tree shrews share many striking similarities with primates. But it is also true that all of these similarities can probably be ascribed to one of the following two categories: (1) retention of characters unchanged from the common ancestral placental mammal stock; (2) convergent development of adaptations for life in the trees. A convincing case could only be made for regarding the tree shrews as primates if it were possible to postulate the development of specific characters in a definable ancestral stock derived from the ancestral placentals and giving rise to tree shrews and 'other' primates. Exclusion of the tree shrews from any phylogenetic link with the primates owes as much to increasing attention to the principles of phylogenetic reconstruction as to the discovery of new evidence. As Romer suggested (*Notes and Comments on Vertebrate Paleontology,* University of Chicago Press, 1968), it now seems likely that the tree shrews, rather than providing a living model for the ancestral primate (the view espoused by Le Gros Clark and Simpson), probably provide a better indication of the characteristics of the common ancestor of all living placental mammals.

One major drawback in discussions of the phylogenetic ties of the tree shrews has always been the absence of any clearly identifiable fossil relatives. The Oligocene *Anagale* was, for a while, regarded as an early relative of the tree shrews (Le Gros Clark *The Antecedents of Man,* 2nd ed., Edinburgh University Press, 1971), but has now been assigned to the Lagomorpha (rabbits and hares) (McKenna *Am. Mus. Novit.* **2158**, 1; 1963). Van Valen (*Evolution* **19**, 137; 1965) suggested *Adapisoriculus* as a Late Palaeocene tupaiid, but the fact that this fossil genus has been variously assigned to the marsupials, the insectivores and the tree shrews simply underlines the very generalised morphology of *Adapisoriculus* and the modern Tupaiidae. Strangely, although inferred phylogenetic relationships among mammals have been traditionally based heavily on dental morphology, the dental characters of tree shrews have been barely mentioned in discussions of their evolution. In fact, they exhibit a combination of somewhat unusual specialisations of the anterior teeth with a basically primitive configuration of the cheek teeth. Apart from the loss of one premolar in both upper and lower jaws, they depart only slightly from the pattern postulated for ancestral placental mammals.

The new material from the Sivaliks assigned to *Palaeotupaia sivalicus*, in spite of its fragmentary nature and the absence of any information on the lower jaw, shows clear similarities to modern tree shrews (actually to the Tupaiinae, rather than to the Ptilocercinae). The upper cheek teeth have a similar, basically primitive configuration, while the anterior part of the maxilla together with a premaxilla is similarly drawn out into a rostrum with a small canine posteriorly and two large, well-spaced incisors arranged longitudinally and separated by a large median gap from their counterparts. The upper dentition apparently had the same formula (2.1.3.3) as in all modern tree shrews, and the overall arrangement of the dentition, upper jaw, snout and orbital region is remarkably like that of modern *Tupaia*. Interestingly, although the fragments indicate a skull size comparable to that of the most arboreal modern *Tupaia* species (*T.minor*), the snout is longer and generally more like that of the more typical semiterrestrial *Tupaia* species. This confirms the suggestion (Martin *Man,* **3**, 377; 1968; *Symp. Zool. Soc. Lond.* **33**, 301; 1973) that some of the primate-like features of modern *Tupaia minor* (Le Cros Clark *The Antecedents of Man*), not seen in semi-terrestrial or terrestrial tree shrew species, are independent acquisitions associated with increased arboreal adaptation and as such are of no direct relevance to primate ancestry.

Unfortunately, we still have no fossil evidence relating to the early origins of the tree shrews or their evolution over some 50 million years or more up to the Miocene,

---

R.D. Martin is Reader in Physical Anthropology at University College London

0028-0836/79/380178-02$01.00

but the new Sivalik finds do at least document the presence of tree shrews of modern aspect in India some 10 million years or so ago, perhaps contemporaneously with such undoubted prosimian primates from the Sivaliks as *Indraloris* (Lewis *Am.J.Sci.* **26** 134; 1933; Tattersall *Postilla* (Yale) **123**, 1; 1968). □

Origin of the Galilean satellites and Jovian rings

from David W. Hughes

REGULAR satellite and ring systems seem to be a common feature of the major planets. These systems are coplanar, the orbits are circular and also the ratio between the orbital radius of a satellite and that of the one immediately interior is a constant, about 1.65 in the case of Jupiter.

The formation of satellites as the planets condensed has often been linked with the formation of the planets as the Sun condensed, and this process has been re-investigated by Prentice and ter Haar in a recent edition of *Nature* (**280**, 301; 1979). These authors return to the hypothesis originally advanced by Laplace in 1796. In the beginning, according to Laplace, the solar and planetary material was in the form of a huge spinning gaseous globe with a diameter larger than that of Neptune's orbit. As this great globe cooled it contracted, spinning faster and faster due to the conservation of angular momentum. A stage was eventually reached when the equatorial centrifugal force became larger than the gravitational force and a ring of matter was left behind, suspended in a circular orbit in the equatorial plane. Due to this mass and angular momentum loss, the proto-Sun could contract a little further, but it soon became unstable again and shed another ring. This process was repeated until the Sun reached its present size.

Now it must be remembered that the present mass of the Solar System is only a very small fraction of the mass of the rings, simply because most of the planets consist of material that is quite rare by normal cosmic standards. Each planet is probably the condensation remnant of a ring of about a thousand times the Earth's mass. Also the spinning gaseous globe was probably strongly turbulent. By considering T. Tauri stars Prentice (*Astr. Astrophys.* **27**, 237; 1973) concluded that the convective velocities in the globe are supersonic and that the turbulent stresses set up by these convective movements are of the order of 30–100 times the normal gas pressure just below the surface. Two things result from this. First, the globe becomes very centrally condensed which obviously leads to a low moment of inertia. Second, a dense shell of non-turbulent gas develops at the surface, this evolving into an equatorial belt as the cloud contracts. It is this belt which is left behind when centrifugal force exceeds gravitational force, and it can be shown that the ring-shedding process repeats itself at a sequence of orbital radii R_n which satisfy

$$R_n/R_{n+1} = (1 + m/M_e f)^2.$$

In this equation m is the mass of the ring, M_e is the mass of the gaseous globe that has just lost the ring and f equals $I_e/M_e R_e^2$ where I_e and R_e are the moment of inertia and radius of the globe.

For the specific case of the Galilean satellites of Jupiter Prentice and ter Haar set M_e to 1.9×10^{30} g the present mass of Jupiter, f to 0.02 and R_n/R_{n+1} to 1.65. This immediately tells us that the mass of each Jovian ring was about 1.1×10^{28} g. If this mass was of solar composition it would have two medium-temperature (~0°C) solid components. The rocky one would have a mass of about 5×10^{25} g and the water ice and rock mixture component would have a mass of about 12×10^{25} g. The globe is warming up as it condenses so each detached ring will have a different temperature. The authors calculate that the temperatures at detachment for Io, Europa, Ganymede and Callisto are 533, 338, 220 and 133 K respectively. It is this temperature difference which causes the chemical variation. Io and Europa with masses of 9×10^{25} and 5×10^{25} g, respectively, have little ice, the high-temperature Io condensation having iron in the form of FeS while for Europa, Fe appears as FeO. The heat released as the ring condenses to form a satellite and as the satellite compacts causes S and H_2O to leak out, leaving sulphur deposits on Io and icy plains on Europa. Ganymede and Callisto condensed at a temperature below the freezing point of water and therefore consist of dirty ice.

By extending this theory, the authors predict that the contracting gaseous globe can shed one or two more rings interior to Io. One has a radius of 2.5 R_p and the other 4 R_p where R_p is the present Jovian polar radius, 6.677×10^9 cm. Amalthea is near the first of these but is spectrally very close to a C-type asteroid and has probably been captured by Jupiter at a later date. These interior gaseous rings probably did not condense to form satellites because there was too little time for the rocks to aggregate into a single body before the gaseous component of the rings dispersed, taking with it the finer dust material. Also the increasing luminosity of proto-Jupiter probably frustrated the settling out process.

Ring shedding cannot proceed indefinitely. The rate of release of gravitational potential energy slows down between 3 R_p and 1.5 R_p in the case of Jupiter. This results in a decrease in the surface temperature and in the supersonic turbulence. R_n/R_{n+1} drops to 1.02, leaving the rings so closely spaced that they essentially merge together to form a continuous disk. The disk does not coalesce into a few single bodies because of its differential rotation. The gaseous component disperses and orbital resonance subsequently changes its structure. It is these resonances which may account for the sharp ring edge seen at 1.9 R_p by the Voyager I and II spacecraft.

No theory in cosmogony is without its rival and the origin of the Jovian rings is no exception. Smoluchowski wrote in the following issue of *Nature* (**280**, 377; 1979) that the rings were probably produced by the tidally induced fragmentation of a non-spherical, mechanically weak carbonaceous body. This disruption is thought to have occurred fairly recently. The solid surface area of the rings has been estimated to be about 20,000 km², this value coming from a comparison between the decrease produced in the charged particle flux by the rings and that caused by Amalthea, both these effects being observed by Pioneer 11. Bombardment by the intense flux of protons in the Jovian Van Allen belts erodes particles. Smoluchowski calculated that ice was eroded at between 50 and 100 Å yr^{-1} and silicate particles at 2–3 Å yr^{-1}. Many small grains are thus eliminated on the time scale of a million years and the Jovian rings are not expected to have a lifetime much longer than this. □

Normal fluid density of superfluid ^{3}He-B

from P. V.E. McClintock

NEW high precision measurements of the normal fluid density of liquid ^{3}He-B have yielded some surprises. In particular, it seems that the so-called 'stripped' normal fluid density is independent of pressure, quite contrary to expectation. The experiments were carried out by Archie, Alvesalo, Reppy and Richardson of Cornell University and are reported in a recent issue of *Physical Review Letters* (**43**, 139; 1979).

The hydrodynamic properties of the B-phase of ^{3}He are relatively simple in that the liquid can conveniently be described in terms of a two-fluid model, qualitatively very similar to that which has been used in relation to superfluid ^{4}He for many years. Thus, the liquid is envisaged as being composed of two quite separate but completely interpenetrating fluids: a normal fluid component whose properties are similar to those of conventional liquids; and a superfluid component able to indulge in dissipation-free flow, carrying no entropy, and responsible for much of the seemingly bizarre behaviour exhibited by

0028-0836/79/380179-02$01.00

the liquid. Properly speaking, of course, because ^{3}He is a fermion (containing an odd number of fundamental particles) its superfluid phases are more closely analogous to the gas of electrons (also fermions) in a superconducting metal than they are to superfluid ^{4}He, which is a boson (even number of fundamental particles). Thus, the origin of the two-fluid behaviour can be understood in terms of a modified form of the well known BCS theory of superconductivity, with an energy gap separating the ^{3}He atoms which exist in the paired zero-energy state (superfluid component) from the atoms in ordinary unpaired states (normal fluid component). In the A-phase, the energy gap is anisotropic, that is, the effective magnitude of the gap depends on direction within the liquid. It follows that the normal fluid density also depends on direction, rendering the hydrodynamic properties complicated in the extreme. The energy gap and normal fluid density in the B-phase, on the other hand, both turn out to be isotropic, and so the situation is a good deal simpler.

Measurement of the normal fluid density ϱ_n as a function of T/T_c is potentially able to provide a great deal of information about the attractive interaction between the ^{3}He atoms which gives rise to the formation of pairs, and which is therefore responsible for the superfluidity. Here T is the temperature and T_c is that of the superfluid transition. The interaction is in fact extremely complicated, because the very act of forming the pairs in turn modifies the interaction. Much effort is being directed towards gaining an understanding of this so-called strong coupling effect.

The technique used at Cornell for measuring ϱ_n entails shaking the liquid back and forth in a container sufficiently narrow that viscous forces constrain the normal fluid to move, thus contributing to the moment of inertia, whereas the superfluid component slips freely and makes no contribution. The apparatus involves liquid ^{3}He held inside a cell shaped like an inverted mushroom, with a thin coin-shaped cavity in its cap. The stem of the mushroom is a springy beryllium-copper tube which is used not only for filling the sample of ^{3}He but also for providing the restoring force enabling the cap to undergo torsional oscillations. From very careful measurements of the resonant frequency of such oscillations it is possible to deduce the proportion of the liquid which follows the motion of the cap, and hence to calculate the normal fluid density. This type of apparatus has been used before at Cornell. The main importance of the present results is their comprehensiveness, particularly in covering so wide a range of temperatures, achieved by incorporating the experimental cell into a nuclear demagnetisation cryostat.

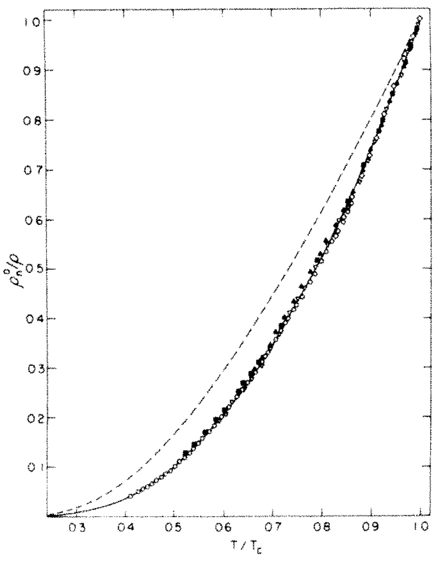

Fig. 1 The stripped normal fluid density ϱ_n^0/ϱ(see text) plotted against T/T_c, where T is the temperature and T_c that of the superfluid transition. On this type of plot the experimental data, recorded for five different pressures between 2 and 29 bar, are clearly pressure-independent and lie well below the weak-field BCS prediction (dashed curve).

Values of ϱ_n/ϱ were measured as functions of T/T_c for several pressures between 2 and 29 bar. Here, ϱ is the total density of the liquid. For any given value of T/T_c, it was found that ϱ_n/ϱ decreased with increasing pressure. The real interest arises, however, when the data are manipulated to give what the authors describe as the "stripped normal fluid fraction", ϱ_n^0/ϱ: in effect, this amounts to removing the known effect of the Fermi-liquid molecular field, the interaction which is present in the normal (non superfluid) liquid at temperatures above T_c. Any deviations between ϱ_n^0/ϱ and predictions based on the BCS approach can then be attributed to strong coupling effects. The result of this operation is shown in Fig. 1. It is immediately apparent that, within the (remarkably small) random experimental error, ϱ_n^0/ϱ is completely independent of pressure. Also, in that there is a sizable difference between the data and the BCS theoretical curve, it appears that there are substantial strong coupling effects, as expected. It would seem, therefore, that the strong coupling effects are themselves independent of pressure.

This is a most unexpected conclusion. It seems to be at variance with other measurements of the strong coupling corrections based on specific heat or sound attenuation data, but to be in reasonable agreement with measurements based on other types of hydrodynamic experiment, once these have been readjusted in the light of the latest temperature scale. Devising an explanation of these results will be an interesting challenge for theorists working in the area and should eventually lead to an enhanced understanding of both superfluid phases of ^{3}He. ☐

All sorts of protoplasts

from Edward C. Cocking

ONE of the most refreshing aspects of protoplast research is that there always seems more to do. At the recent 5th International Symposium*, which covered most aspects of plant, fungal and bacterial protoplasts, it was clear that many laboratories are now using this novel cell system for many basic and applied investigations. Some of the basic studies discussed included pioneering work by L. Vigh and his colleagues at the Biological Research Centre, Szeged on the incorporation of spin-labelled fatty acids into the plasma membranes of intact wheat protoplasts. Significant differences were found between the microviscosity of membranes of cold-resistant and cold-sensitive wheat cultivars indicating that membrane fluidity may be directly involved in avoiding freezing injury — perhaps growth substance workers could find this a useful probe for early effects on the growth of single cells.

With the current interest in genetic manipulation, it was understandable that there should be a major emphasis on the fusion of protoplasts for somatic hybridisation, and on the use of protoplasts for transformation. A particularly useful feature of this meeting was that it afforded the opportunity of comparing progress between prokaryotic and eukaryotic systems. Classical genetic information transfer in bacteria is unidirectional, contrasting with the products of induced protoplast fusion which produces a new entity containing the whole genome and cytoplasm of two or more bacterial cells. L. Alföldi and his colleagues (Biological Research Centre, Szeged) highlighted the limitations of classical methods of genetic analysis when applied to such bacterial protoplast systems. The industrial potential of these interesting recombinants has not, apart from work on *Streptomyces*, been fully exploited yet.

However, the outlook for fungal protoplasts is more encouraging. Many workers have investigated the fusion of the protoplasts from a wide range of fungi. New genetic variability is being produced as a consequence of fungal protoplast fusion, particularly between various *Candida* species that are important in single cell protein production. These basic studies are providing a foundation for many other industrial applications (see Peberdy *Proc. 3rd Int. Symp. Gen. of Industrial Microorganisms*, 1978). Better strains of *Trichoderma* for improved cellulase production are being developed and brewing yeasts could benefit from the readiness with which polyploid strains can

---

*This meeting on Microbial and Plant Protoplasts was held in Szeged, 9-14 July, 1979, jointly organised by the Department of Microbiology, Attila Jozsef University, and the Institutes of Genetics and Plant Physiology, Biological Research Centre. The proceedings will be published by Pergamon.

0028-0836/79/380180-02$01.00

be produced by protoplast fusion methodology. These studies and a refinement resulting in interspecific mitochondrial transfer (L. Ferenczy, Atila Jozsef University, Szeged; R. Dales & J.H. Croft, University of Birmingham, Birmingham), and the now well-documented transformation of yeast protoplasts by chimaeric plasmids, have fully established fungal protoplasts in the forefront of genetic manipulation.

Studies on the reversion of fungal protoplasts were however, not neglected (O. Necas, J.E. Purkyne University, Brno) and the report on chitosomes and the origin of chitin microfibrils (Bartnicki-Garcia, University of California, Riverside) showed the usefulness of protoplasts for elucidating the details, both structural and biochemical, of cell wall synthesis at a naked plasma membrane surface.

Close parallels exist with plant protoplasts in this respect, but the more exacting developmental processes involved in whole plant regeneration have restricted the range of species for plant genetic manipulations. Several workers emphasised the difficulty in releasing the probable inherent totipotency of single cell cereal cultures—isolated cereal protoplasts are the 'acid test' for such regeneration capability. Chinese workers reported limited success in obtaining a few cell divisions in cultures of wheat leaf mesophyll protoplasts. Protoplasts isolated from suspension cultures derived from callus of pearl millet immature embryos were reported to divide to form embryoids and subsequently whole plants (I.K. Vasil & V. Vasil, University of Florida, Gainesville). Several participants doubted whether this system would be reproducible, and also whether the approach adopted would be applicable to the main cereal crops; but this report will no doubt greatly stimulate work on cereal protoplasts.

Virus replication studies using plant protoplasts do not depend on such a full developmental sequence; and have provided an important clue to the various resistance barriers that may be by-passed using protoplasts: I. Takebe (Nagoya University, Nagoya) reported that radish mesophyll protoplasts are readily infected by brome mosaic virus which shows no evidence of infection in radish leaves.

A somewhat similar breakdown of infectivity barriers is suggested by the reports of the transformation of plant protoplasts by isolated *Agrobacterium* plasmids — in future it may prove possible to transform protoplasts of monocotyledons although *Agrobacterium* itself infects dictotyledons only. If this is coupled with the ability to regenerate whole plants, a sound basis could be provided for the transformation of cereals.

Understandably most of the somatic hybridisation work using plant protoplasts has utilised more culturally amenable species. Although several somatic hybrid plants have been obtained between species that have not, as yet, been crossed sexually this has not resulted in the production of useful amphidiploids. It is still not clear whether chromosome elimination in heterokaryons of disparate species will result in cybrid formation, with the possibility of mitchondrial recombination as suggested from the restriction nuclease analysis of G. Balliard and G. Pelletier (University of Paris-Sud, Orsay) or regeneration of plants with only very limited gene transfer. There is obviously the possibility of such somatic transformation using disparate plant protoplast combinations (D. Dudits *et al.*, Biological Research Centre, Szeged).

There was general agreement that only continuing research on all these various aspects of protoplasts will provide an adequate foundation for applied developments. □

Twenty years of pheromomones

by Mary Lindley

THE exchange of chemical signals between living organisms has proved to be far more complicated than it seemed twenty years ago, when pheromones were first defined as substances responsible for chemical communication among individuals of the same species. Through the combined efforts of chemists, ecologists and physiologists, concentrating chiefly on insects, the original idea that one substance served one species has given way to the realisation that the pheromome secreted by a particular species is a characteristic mixture of components. Each component has a particular function in communication within and between species, affecting the behaviour involved in, for example, attraction, inhibition and alarm. Electrophysiological studies of insect chemoreceptors, such as those on antennae, have shown that different cells respond to different components, and that the central nervous system interprets the resulting signal according to the level of excitation of the various cells.

The realisation that there is more to chemical communication than sexual attraction has necessitated a more extensive classification of the chemicals involved. When individuals of different species communicate chemically, the signal is a kairomone if the receiver benefits, as in the case of certain predators of bark beetles which aggregate in response to secretions from their prey. If the sender benefits, however, the signal is an allomone, such as those produced by orchids of the genus *Ophrys* to attract the bees that pollinate them. Some of the contributors to the growing understanding of chemical communication gathered recently in Sweden*. Among the inevitable and essential accounts of further pheromone components isolated and synthesised, there were some descriptions of newly recognised chemical relationships and progress reports on the application of pheromones in pest control.

As sex attractants, pheromones have been considered primarily to be produced by females to attract males, but this is not always the case, and D. Schneider (Max-Planck-Institut für Verhaltenphysiologie, Seewiesen) described one produced by male monarch butterflies (family Danaidae). Through thin hairy organs, known as hairpencils, they release a pheromone to prepare the females for mating. Its principal component is a heterocyclic ketone — danaidone — synthesised from precursor alkaloids taken up by the butterflies from certain food plants. Synthesis of danaidone also often requires contact between the hairpencils and the male's wing gland. Together with cardiac glycosides, the alkaloids also serve as chemical defence agents which render the butterflies unpalatable to some of their predators.

R. Baker (University of Southampton) believes that some of the most successful West African predatory ants have become specialised so that their pheromones, used in alarm and recruitment of nest mates, are not detected by their prey (*Experientia* in the press). The workers of some species of myrmicine ants can move freely within the galleries of termites before attacking the inmates and carrying them to their own nests. But when the Southampton group exposed termites to workers of related species of ants, the termites retreated. Bioassays and analysis of the secretion of the mandibular gland in various myrmicine ants have shown that the specialised or semi-specialised predators produce aliphatic alcohols, which do not affect termites, instead of carbonyl or other compounds, which are usually repellant to termites. Baker suggested that the secretions of the ant's mandibular glands may provide clues by which termites recognise predators, and that the most successful predators are those producing secretions the termites cannot detect.

When attention turned to pest control, there were enthusiastic reports of some of the programmes that have been set up throughout the world. The general response, however, was less enthusiastic, with discouraging references to unobtainable patents and the strict standards of environmental agencies more

*A conference entitled "Chemistry of Insects: Chemical Interaction and Communication" was held in Borgholm, Sweden on 13-17 August 1979. It was organised by G. Aulin-Erdtman of the Swedish National Committee for Chemistry of the Royal Swedish Academy of Sciences, and sponsored by Euchem and the Swedish National Committee for Chemistry.

0028-0836/79/380181-02$01.00

familiar with toxic pesticides than behaviour-modifying chemicals. Although nobody could foresee pheromones alone taking care of pest control, there was nevertheless a general hope that they would decrease the present dependence on pesticides.

Mass trapping — large scale capture of pests in traps baited with pheromones — forms the basis of several programmes. A. Shani (Ben-Gurion University of the Negev, Be'er Sheva) pointed out that Israeli farmers spray their cotton fields with pesticides less often than was necessary before mass trapping of the Egyptian cotton leaf worm, *Spodoptera littoralis*, began in 1975. Mass trapping is also the basis of the Norwegian campaign against the spruce bark beetle, *Ips typographus*. Although the beetle is usually a valuable member of the forest ecosystem, accelerating the decay of dead wood, its population has grown so rapidly during the past 10 years that much of Norway's spruce forest is threatened. L.A. Riege (Borregaard Industries Ltd, Sarpsborg) felt that there were signs of success in the catches of the 600,000 traps set up this year with a lure of bark beetle pheromone.

G.N. Lanier (State University of New York, Syracuse) reported progress in trials with the aggregation pheromone of the European elm bark beetle, *Scotylus multistriatus*, the carrier of the fungus that causes Dutch elm disease. Lanier has seen a decline in the incidence of diseased trees in trial areas during the past year. He spoke enthusiastically of the potential of this sort of control programme if accompanied by other precautions, such as the proper removal of infected wood.

L. Rechav (Rhodes University, Grahamstown) has been attacking the tick *Amblyomma hebraeum* by painting cattle with a mixture of tick pheromone and acaricide. Small areas of the mixture attract unfed nymphs and adults, killing them before they bite the cattle, thus reducing the chance that they will spread disease. However, this method has the disadvantage that tick assembly pheromones are species specific and remain effective on the cattle for only three days, precluding widespread application at present.

The aim is not always to trap and kill insects, but sometimes to confuse them by filling the atmosphere with pheromones so that the males cannot find the females. The only effective way to monitor the results of such methods is to count the larvae that hatch in a test area, and the results can be distorted by the arrival of gravid females from untreated areas. In tests of the efficacy of mating disruption by pheromone inhibitors of the striped rice stem borer, *Chilo suppressalis*, at the International Rice Research Institute in the Phillipines, this problem has been overcome by the use of large field cages. P.S. Beevor (Tropical Products Institute, London) said that it had been possible to quantify rates of release that would disrupt mating up to 100% in this way. The next stage will be to microencapsulate the inhibitors for slow continuous release and set up trials in the open field. As with similar test programmes, however, the outcome cannot be predicted.

A third practical application of pheromones is to attract pests for population monitoring. Baker reported the early stages of a programme to monitor the pine beauty moth, *Panolis flammea*, a pest of lodgepole pine in Scotland. Once the most effective formulation of pheromones has been worked out, traps will be set up to capture sufficient moths to reflect variations in the size of the populations.

Participants were glad to note that monitoring is already routine in many areas, with commercially produced traps, pheromones and dispensers being used to forecast the size of pest populations. On the basis of the numbers caught in the traps, farmers and their advisors decide how often to spray with pesticides, and there has been a general reduction in the frequency of spraying. Pests being monitored in this way include the pea moth, *Laspeyresia nigricana* in England and northern Europe, the codling moth, *L. pomonella* throughout Europe, *S. littoralis* is Israel and the pink bollworm, *Pectinophora gossypiella* in California.

Pheromones may have uses beyond the continuing battle against pests. The declining population of honey bees, *Apis mellifera*, in Britain and the unattractive nature of arable crops have stimulated attempts to use pheromones to bring the two together for pollination of the crops. J.A. Pickett (Rothamsted Experimental Station, Harpenden) described how this work has brought an unexpected insight into the way the bee apparently controls its output of pheromone components. The Nasunov gland, between the sixth and seventh segments of the body, produces several components, of which (E)-citral is the most active in attracting other bees, although it is very volatile and present in very small quantities. Pickett and his colleagues have found that the gland has a highly specific enzyme system that converts geraniol to (E)-citral. He suggested that this system controls the release of (E)-citral, ensuring that it is present in sufficient quantity to be active.

The way in which insects synthesise their pheromone components and release them in precise proportions are problems for the next twenty years, together with the mode of action at the receptors and the subsequent fate of the pheromone. Meanwhile there are plenty more pheromones to be isolated from an abundance of insects. □

A hundred years ago

The French Association for the Progress of Science has taken a bold step and decided that its session for 1881 will take place in Algiers. To avoid the numerous inconveniences of the strong heat which prevails all over Algeria in the month of August, it has been decided that the meeting should be held in April, during the Easter recess.

This happy result of the deliberations must be attributed to the personal exertions of M. Albert Grévy, the brother of the President of the French Republic, who holds the post of Civil Governor-General of Algeria.

It is supposed that the new scientific establishment whose formation has been decreed this year, will be formally inaugurated on this occasion, and a scientific movement of some importance will take place in the colony.

The *Akhbar* announced a few days back that a geographical society is being organised in Algiers.

In the meantime a number of representatives headed by Algerian senators and deputies will make a tour of exploration during the month of October. They will start at the end of September, as we announced some weeks ago. They will witness an agricultural and horticultural exhibition, which is to be held at Bone, for the whole of Algeria and Tunisia, and which will be held in Algiers in 1881.

The most successful lecture this year at Montpellier, was organised by the Languedocian Society of Geography. MM Solcillet, Brau de Saint Pol Lias, Director of the Sumatra Exploring Company, and other explorers or intending explorers, appeared before the public on that occasion. M. Rabaut, the President of the Society of Geography of Marseilles, and the commercial agent for the Sultan of Zanzibar, gave most interesting details of the several explorations at present going on in that part of the Dark Continent.

The lecture on the progress of electricity was given by M. Denayrouze, of Jablochkoff candle notoriety. The speaker tried to show that Jamin's candle ought to be superior to the light which is spreading so largely in Paris and in London.

The British Association

Report of the Committee for exploring Caves in Borneo. Drawn up by Dr. J. Evans F.R.S. — The Committee report that with the grant of 50 l. from the Association, a similar grant from the Royal Society, and a farther sum of 200 l. from private sources, they have been able to prosecute an examination of various caves in Borneo, under the superintendence of Mr. A.S. Everett, who has devoted himself to the task for a period of nearly nine months.

The final report upon his work has not yet been received, but it appears from his letters and from the specimens which have been transmitted to this country, that nothing of special interest either from an anthropological or a geological point of view has resulted from his explorations.

A binary star model for SS433

D. S. De Young
National Radio Astronomy Observatory, Charlottesville, Virginia 22901

Geoffrey Burbidge
Kitt Peak National Observatory, Tucson, Arizona 85726

The novel features recently observed for the strong emission line object SS433 can be explained by a model in which SS433 is a binary of a massive early-type star and a magnetic white dwarf.

RECENT observations by Margon *et al.*[1,2] and Liebert *et al.*[3] of the strong emission line object SS433 have revealed some extremely interesting and unusual features. Most prominent among them is the presence of strong emission lines of hydrogen and neutral helium which show simultaneous, large redshifts and blueshifts of up to $+50{,}000\ \mathrm{km\ s^{-1}}$ and $-30{,}000\ \mathrm{km\ s^{-1}}$. These shifts are relative to a nearly stationary line system[1] of velocity $\leqslant 180\ \mathrm{km\ s^{-1}}$. The detailed line structures are complex and show smaller velocity variations on a scale of days[1,3], as well as variations of linewidth from 50 to ~200 Å. A second unusual characteristic is that the red- and blueshifted systems merge to a common velocity[4] of $\approx +10{,}000\ \mathrm{km\ s^{-1}}$ with an apparent period of 160 ± 3 days[2,4], thence returning to high red- and blueshifted values. Moreover, there seems to be no evidence of eclipsing of the high velocity features during a period; the period is consistent with a sinusoidal form, and there may be evidence for non-Keplerian motion in the high velocity features[4]. Margon *et al.*[1] deduce a distance to SS433 of $\geqslant 3.5$ kpc, giving $M_v \approx -3.5$. To a limit equivalent to that of the Sky Survey plates, the object appears stellar and is considerably reddened[1]. A search for optical polarisation[3] has produced an upper limit of 0.1%. Seaquist *et al.*[5] have observed SS433 at radio frequencies over a period of 18 months and found variations on a scale of hours to weeks at centimetric wavelengths, with changes of flux of up to factors of ~2.5 (200 to 500 mJy) on the longer time scale. Neither linear nor circular polarisation was detected at 2.7 and 8.1 GHz, and spectral information available suggests a non-thermal origin for the radio emission. VLBI observations of SS433 at 21 cm show no structure on a scale of several milliarc seconds down to a limit of ≈20 mJy (R. Sramek, personal communication). Finally, the object may be associated with the X-ray source A1909+04[1].

Constraints on models

A viable model for SS433 must primarily account for: (1) the large luminosity in the emission lines of $\sim 10^{34}\ \mathrm{erg\ s^{-1}}$; (2) the large redshifts and blueshifts relative to a nearly stationary system; (3) the periodic merging of these features to a value of $+10^4\ \mathrm{km\ s^{-1}}$; (4) the stellar appearance of the object; and (5) the observed emission at radio and X-ray frequencies. For a brightness temperature of $\sim 10^4$ K; (1) implies that the Hα emitting region must have a size $\sim 10^{12}$ cm if the emission comes from an optically thick gas, as appears to be the case[3]. This eliminates accretion onto a neutron star, since the accretion radius is much smaller than 10^{12} cm. Similarly, Zeeman splitting in the magnetosphere of such a star to produce (2) is eliminated because no significant optical polarisation is present[3]. Terlevich and Pringle[6] have proposed a model for SS433 which involves accretion onto a $3 \times 10^5 M_\odot$ black hole, while Fabian and Rees[7] have suggested that oppositely directed high-speed jets emanate from a central source of unknown nature. Both of these models, in their present form, can account for the observed characteristics except for the periodic merging to a high velocity required by constraint (3).

A binary star model

We propose that SS433 is a member of a class of astrophysical systems whose existence has been confirmed by observations; that is, we suggest that SS433 is a binary star system comprised of a massive early-type star and magnetic white dwarf. As we describe below, the observed characteristics of the system can arise if the rotating white dwarf possesses gas imbedded in a dipole field either aligned with or at large obliquity to its spin axis, and with the plane of the orbit lying nearly in the plane of the sky. Precession, but more probably nutation, induced by dissipative interaction with the primary can give rise to the apparent periodicity.

Production of the shifted emission lines: The general characteristics of magnetic white dwarf stars have recently been reviewed by Angel[8]. Typical masses and radii are $\sim 1 M_\odot$ and 10^9 cm. Inferred surface magnetic fields range from 10^7 G to $>10^8$ G; the upper limit of the surface field is uncertain, and 10^9 G is not excluded. A firm upper limit is reached at 10^{12}–10^{13} G when the magnetic field energy density reaches balance with the hydrostatic pressure. Rotation periods vary from ~1 min to $\leqslant 100$ yr, and a considerable offset between the rotation axis and the magnetic field symmetry axis is often indicated. Simple dipole field structure is evident.

For SS433, we must first obtain an estimate of the energy density in the emission line regions. This is not well determined if the region is truly optically thick because of ambiguity in the number density n. If, however, one assumes that all of the emission eventually escapes in the wings of the lines, a value for n may be obtained [we are indebted to R. L. Brown for pointing this out]. Terlevich and Pringle, apparently following this reasoning, arrived at $n \sim 10^{12}\ \mathrm{cm^{-3}}$, although this number is by no means secure except as an upper limit. The presence of large optical depth and the absence of pressure broadening of the lines implies n to be $\sim 10^{10}$–$10^{12}\ \mathrm{cm^{-3}}$, in which case $nkT \sim 10^{-2}$–1 in the emission line region. These energy densities may then be compared to the magnetic field strengths at a distance of $r = 10^3 R_* = 10^{12}$ cm, where R_* is the radius of the magnetic white dwarf. A dipolar surface field of 10^9 G will have a strength of ~1 G at this radius, and thus the line emission regions at 10^{12} cm can be dynamically controlled by the magnetic field. Gaseous

0028-0836/79/380183—03$01.00

material has the easiest access onto magnetic field lines in the polar cap regions, and thus we suggest that the emission lines can arise from material forced into near co-rotation at $r \sim 10^{12}$ cm above the two polar caps of a dipole field offset at nearly 90° from the rotation axis.

The velocities required are $\sim 0.15c$, which at $r = 10^{12}$ cm, implies a rotation period of ~1,500 s, which is well within the observed range for such stars. In order for the star not to be disrupted at this angular velocity, we require $\omega^2 R_* < GM/R_*^2$, or $R_* < 2.5 \times 10^{10} M_\odot^{1/3}$ cm, a condition easily satisfied by a white dwarf. Neglecting for the moment the orbital considerations, material in the polar cap regions will be seen to move towards, or away from the observer with a frequency shift given by

$$\nu_{\text{em}}/\nu_{\text{obs}} = \gamma(1 - \beta \cos \theta) \qquad (1)$$

where θ is the angle between the velocity vector and the line of sight.

In addition to the co-rotation, the emission line regions also undergo centrifugal acceleration. At $r = 10^{12}$ cm material in the polar cap regions must be accelerated away from, rather than accreted onto the star, since $\omega^2 r = GM/r^2$ at $r = 2.45 \times 10^{10}$ cm. Thus material injected onto field lines at radii less than $10^3 R_*$ will acquire a radical velocity

$$v_r(R) = \int a(r)\,\mathrm{d}t = \int \frac{a(r)}{v_r(r)}\,\mathrm{d}r;$$

$$a(r) = \omega^2 r - GM/r^2 \qquad (2)$$

If injection occurs near the equilibrium radius, then equation (2) yields $v_r \sim \omega r \approx 0.1c$ at $10^3 R_*$, comparable to the co-rotation velocity. Because of this centrifugal acceleration, gas at 10^{12} cm may not be in exact co-rotation if $\rho v_r^2 > B^2/8\pi$. The magnitude of this effect is unknown due to the uncertain values of the gas density and the magnetic field strength at the surface of the white dwarf. The absence of forbidden lines[9] implies a lower limit to the gas density of about 10^8 cm^{-3}; a surface field of $\sim 10^{11}$ G will provide exact co-rotation in this case. In either case, velocity shifts of +50,000 km s^{-1} and −30,000 km s^{-1} are achieved from equation (1) with a value of $\gamma = 1.033$ and a maximum value of $\cos \theta$ of ±0.5. Thus the observed velocity extremes result when the plane containing the polar caps is inclined at about 30° to the plane of the sky.

The total amount of gas in the emitting region is small; $m_g \sim 10^{-12}$–$10^{-10} M_\odot$, depending on the uncertain value of n, with $10^{-10} M_\odot$ being an upper limit. A similar value for the mass was obtained by Fabian and Rees. Beyond the line emitting region the expanding gas cools in the rapidly diverging field, and the observed line widths result from absorption by the gas of much larger column density which lies above the polar caps; that is, emission is seen only when the poles lie near the sky plane; at other times it is blocked by the larger volume of cooler gas in the line of sight above the polar region facing the observer. The small mass of gas in the line-emitting region can be produced by activity near the surface of the white dwarf triggered by infall of material at lower radii[8]. The infall may arise from direct accretion, or more probably from gas trapped on closed field lines at earlier epochs. In either case ejection is possible only along the open field lines at the poles, and the mass injection rate is $M \approx R_{\text{em}}{}^2 \rho_{\text{em}} v_{r,\text{em}} = 10^{-14} M_\odot\,\text{s}^{-1}$, where the subscript 'em' refers to conditions in the emission line region. This small value is at the low end of estimates for accretion onto magnetic white dwarfs[10].

Origin of the periodicity of the emission lines: With the value of $\gamma = 1.033$ needed to obtain the maximum and minimum velocities of the emission lines, the observed periodic nature of these lines follows directly if the plane containing the magnetic poles moves through an angle of ~30° with a period of ≈160 days. This shifts the plane of rotation into the sky plane with a uniform merging of the emission line velocities to a common value of $+10^4$ km s^{-1} given by the transverse Doppler effect (equation (1), $\theta = 90°$) at $\gamma = 1.033$. For a near 90° offset of magnetic and spin axes, this implies a 15° precession or nutation angle of the spin vector. During that portion of the period when the pole caps lie in the sky plane, emission is seen from both polar regions. One result of this configuration is that the emission lines will vary in intensity with a period of $\sim 10^3$ s when the lines are at the extremes of their velocity shifts, but that no pulsation will be observed when the lines merge to a common velocity.

Another possibility is that the magnetic field axis is aligned with the spin axis, and that gas is accelerated outwards along the open field lines above the poles. In this case no variation in intensity would be observed, since the line emitting regions would be at all times visible to the observer. Preliminary results from MMT observations[11] indicate little variation on short time scales (~1 to 100 s) and may favour an aligned spin and magnetic axis model. However, such a model also requires a 15° precession or nutation of the spin vector.

The orbital characteristics of the white dwarf can only be determined indirectly, since its magnitude at 3.5 kpc is $m_v \approx 26$–29. A commonly observed configuration is for the spin and orbital angular momenta to be near alignment; this geometry would place the orbital plane of the white dwarf roughly in the sky plane and account for the observed lack of eclipsing of the emission lines. It can easily be shown that precession or nutation driven by the usual gravitational torques upon a non-spherical magnetic dwarf cannot produce the required period, even for extreme differences in the principal moments of inertia[12]. To do this would require either an immensely massive primary ($10^6 M_\odot$) or an orbital radius much smaller than the dimension of the line emitting regions. However, either viscous, dissipative coupling or magnetic coupling between the white dwarf and the primary will also exert a torque upon the white dwarf. The maximum co-rotation radius of the magnetic field surrounding the white dwarf is $\sim 10^{13}$ cm, thus an orbital radius of ~10 times the size of emission-line regions will provide strong coupling between the stars.

To see if such coupling can produce the required period, we use the standard Euler equations[13] where the Euler angles ϕ, θ and ψ have their usual meaning. We assume that the star is not grossly deformed, so that the moments of inertia $I_1 \approx I_2 \approx I_3 = I$. If T is the total torque exerted by the coupling upon the star, $\vec{T} \approx \vec{F}_{\text{d}} \times \vec{R}$ where F_{d} is the drag force and R is the radius of the orbit. A condition of constant precession, namely $\ddot{\theta} = \dot{\theta} = 0$, and negligible spin down, $\ddot{\psi} \approx 0$, can be found with the required precessional frequency $\dot{\phi} \approx T \sin \theta/(\omega_s I) \sim 10^{-7}$ s^{-1}, where $\omega_s = \dot{\psi} \sim 10^{-3}$ is the spin of the star and $\theta \sim 15°$. However, in this case the third Euler equation yields $\ddot{\phi} \sim 10^{-3} \dot{\phi}$ which implies a very rapidly evolving set of orbital parameters.

A more stable system seems much more probable, and hence we consider nutation ($\dot{\theta} \neq 0$) and slow variation of the other orbital characteristics. For small obliquity, negligible spindown, and a precession period long compared to nutation period, a periodic solution $\ddot{\theta} \approx -T\theta/I$ exists, with nutation frequency $= (T/I)^{1/2}$. Setting this equal to the required value of 10^{-7} s^{-1} yields $F_{\text{d}} = 10^{24}$ for $R = 10^{13}$ and a white dwarf mass and radius of 1 $M_\odot$ and 10^9 cm, respectively. If the coupling is due to viscous drag, the shear between the co-rotating gas and the atmosphere of the primary will be proportional to the gas density, the square of the relative velocity, and the surface area of the shearing region: $F_{\text{d}} = \varepsilon \rho v_{\text{rel}}{}^2 A$, where $\varepsilon \leqslant 1$ is a measure of the coupling efficiency. For $V_{\text{rel}} \sim 10^{10}$ cm s^{-1}, $A \sim 10^{24}$ cm^2, $\varepsilon n_{\text{gas}} \approx 10^4$. Thus for gas densities in the outer envelope of the primary as low as 10^6 cm^{-3}, a 1% coupling efficiency will provide the necessary drag force. This efficiency is higher than that normally encountered in purely gas dynamical situations, and its enhancement may be attributed to magnetic coupling at $R = 10^{13}$ cm.

Another contribution to coupling between the stars arises from interaction between the magnetic fields of the primary and secondary. The luminosity and emission line spectra observed at +180 km s^{-1} imply that the primary is a fairly early type star with mass $\sim 1 - 10 M_\odot$. If, for example, the primary were an Ap star with surface field ~30,000 G and radius 5×10^{11} cm, the magnetic torque induced upon the white dwarf is $T \sim (4\pi/3)B_2 r_2^3 B_1 (r_1/R)^3 \sim 1 \times 10^{37}$, where the subscripts 1 and 2 refer to the primary and to the white dwarf, respectively. The resulting drag force is $F_d = T/R \sim 10^{24}$ dyn, which is the required value. If such coupling is dominant it would imply that SS433 is similar to the model of AM Her suggested by Stockman *et al.*[14]. Radio emission can easily arise in the lower regions of the white dwarf magnetosphere, with the X-ray emission being produced by infall onto the stellar surface[8].

We thank R. L. Brown, J. Liebert, R. O'Connell, S. O'Dell and R. Thompson for helpful discussion, and B. Margon for data. Oxidation of CS_2 and COS: sources for atmospheric SO_2

Jennifer A. Logan, Michael B. McElroy, Steven C. Wofsy & Michael J. Prather

Center for Earth and Planetary Physics, Harvard University, Cambridge, Massachusetts 02138

Oxidation of CS_2 and COS initiated by reaction with OH can provide a source of atmospheric SO_2 as large as 12 Mtonnes S yr^{-1} and may represent the dominant source of SO_2 in remote regions of the marine troposphere.

EMISSION of sulphur associated with combustion of fossil fuel represents a major source of atmospheric pollution[1,2], contributing ~65 Mtonnes S yr^{-1}. Although the chemistry of sulphur in polluted atmospheres has been studied extensively, our knowledge of the natural cycle remains rudimentary. Measurements[3,4] at remote marine locations in the Southern Hemisphere indicate that the atmosphere contains a relatively constant background level of COS and SO_2. We shall argue here that SO_2 is derived at least in part from oxidation of COS, with additional sources due to CS_2 and dimethyl sulphide (DMS).

Sulphurous compounds in the atmosphere

It seems probable that the chemistry of sulphurous compounds in the troposphere should be dominated by reactions involving OH [5–7]. The hydroxyl radical is formed by reaction of $O(^1D)$ with H_2O, and is removed primarily by reaction with CO and CH_4. Results of model calculations for the concentration of OH are given in Fig. 1. We believe that concentrations shown here should be reliable to within about a factor of 2, and uncertainties of this magnitude should not qualitatively affect the arguments which follow.

Sulphur dioxide may be removed from the atmosphere by various heterogeneous processes[8], and by gas phase reactions[5,9] involving OH, HO_2 and CH_3O_2:

$$SO_2 + OH + M \rightarrow HSO_3 + M \qquad (1)$$

$$SO_2 + HO_2 \rightarrow SO_3 + OH \qquad (2)$$

and

$$SO_2 + CH_3O_2 \rightarrow SO_3 + CH_3O \qquad (3)$$

The products in reactions (2) and (3) have not been measured directly, and these reactions may possibly involve formation of adducts. Reaction (1) has been studied by several groups[5,10], using a variety of techniques, and its rate constant is probably known to within about a factor of 2. It constitutes a major, perhaps dominant, path for removal of SO_2. Reaction (3) could be comparable to reaction (1). Considerable uncertainty attaches, however, not only to the mechanism of reaction (3), but also to the concentration of atmospheric CH_3O_2. Reaction (2) is of minor importance.

Studies of SO_2 in polluted air parcels[11,12] suggest an atmospheric lifetime of about a day. Calculations presented here for the marine atmosphere, using the kinetic data summarised in Table 1 but omitting heterogeneous reactions, indicate a lifetime of about 8 days. The difference may reflect in part the role of heterogeneous chemistry, in part omission of processes in polluted air which might be expected to result in higher concentrations of radicals (RO, RO_2). The calculations presented here were carried out using a one-dimensional photochemical model, as described by Logan *et al.*[13], with modifications to their chemical scheme as given in Table 1. Vertical profiles for O_3, CO, CH_4 and H_2O were specified using available observational data and calculations were performed for latitudes 45°N, 15°N, 15°S and 45°S.

Significant quantities of SO_2 may be formed during oxidation of COS and CS_2. It appears[6] that oxidation of COS should be initiated by reaction with OH,

$$OH + COS \rightarrow SH + CO_2 \qquad (4)$$

Subsequent steps may involve production and removal of SO:

$$SH + O_3 \rightarrow HSO + O_2 \qquad (5)$$

$$SH + O_2 \rightarrow SO + OH \qquad (6)$$

$$SO + O_2 \rightarrow SO_2 + O \qquad (7)$$

Rate constants for reactions (5)–(7) have not been determined experimentally. However, it seems reasonable that SH should be oxidised in the atmosphere to SO_2 by reactions (5)–(7) or by some other reaction mechanism. Measurements by Kurylo of the rate constant for reaction (4) and for the corresponding reaction with CS_2 are in conflict with results reported by Atkinson *et al.*[14]. Sources of the discrepancies are discussed in detail in ref. 6, and are attributed to complications due to photolysis of COS and to the occurrence of secondary reactions. Kurylo's experiments were performed in conditions designed to minimise these problems and his rate constants have been adopted accordingly. We estimate a global mean lifetime for COS of 200 days. Combining this lifetime with measured concentrations of COS[4,15], 0.5 ± 0.1 p.p.b. (parts per 10^9, by volume) we infer a global destruction rate for COS equivalent to 4 ± 0.8 Mtonnes S yr^{-1}.

Oxidation of CS_2 can provide a significant source of COS[6,7], through

$$OH + CS_2 \rightarrow SH + COS \qquad (8)$$

Subsequent oxidation of SH, through reactions (5) and (6),

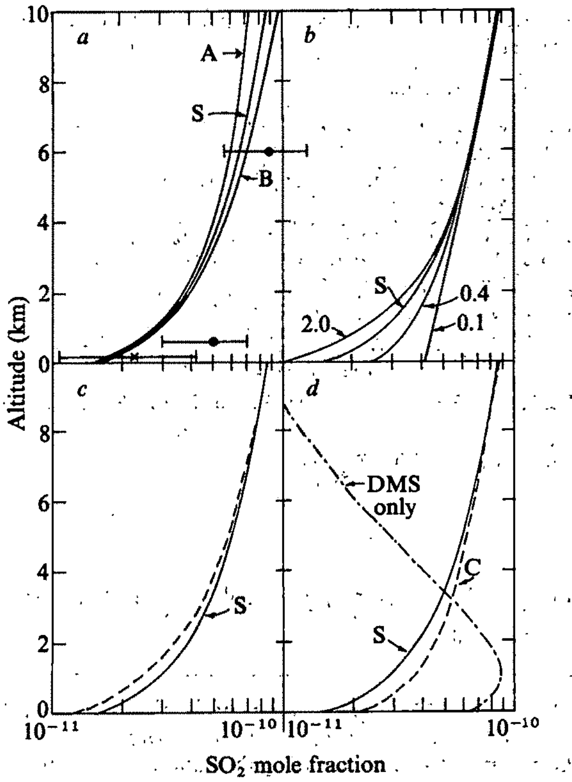

Fig. 1 Altitude profiles for OH and O_3 at 15° S latitude at equinox. *a*, Diurnally averaged concentrations for OH. The model calculations follow the time-dependent variation of short lived chemical species resulting from the diurnally varying radiation field which includes Rayleigh scattering. Calculations are shown for clear sky conditions (A) and a combination of clear sky (70%) and fully reflecting cloud layers at 3 km (17%) and 5 km (13%) (B). Vertical transport is simulated by 'eddy diffusion', with a diffusion coefficient equal to 10^5 cm^2 s^{-1}. The chemical model of Logan *et al.*[13] has been updated as described in Table 1. Fixed profiles for O_3[48] (see *b*), CO[49] (0.6 p.p.b.), CH_4[50] (1.5 p.p.b.) and H_2O (taken from the relative humidity values of Rasmusson[51]) were used. The mixing ratio of $NO+NO_2$ was taken to be 10^{-11} at 0 km, (ref. 52) and a deposition velocity of 1 cm s^{-1} was used for HNO_3. Note that the model implies a value of 1×10^6 molecules cm^{-3} for the globally averaged concentration of tropospheric OH.

should provide an additional source for SO_2. We estimate a lifetime for CS_2 due to reaction (8) of 60 days. Observational data for CS_2 are sparse, confined to the UK[15], and indicate a range of mixing ratios between 0.07 and 0.37 p.p.b. Sandalls and Penkett[15] point out that their data are consistent with the view that the ocean and atmosphere are in equilibrium with respect to CS_2. Using marine measurements of CS_2 by Lovelock[16], and solubility data by Seidell[17], they inferred an equilibrium concentration for the atmosphere equivalent to 0.22 ± 0.06 p.p.b. We adopt this value for the mixing ratio of CS_2 to represent global mean conditions. Used in conjunction with the chemical model of Table 1 and with the OH data of Fig. 1, it implies a global destruction rate for CS_2 equal to 12 ± 3 Mtonnes S yr^{-1}. The associated sources for COS and SO_2 are 6 ± 1.5 Mtonnes S yr^{-1} and 12 ± 3 Mtonnes S yr^{-1} respectively. Note that the source for COS due to oxidation of CS_2 could account for the bulk of atmospheric COS as discussed by Sze and Ko[7].

Source rates quoted here are directly proportional to values calculated for the concentration of OH. Studies of CH_3CCl_3[18,19] suggest that concentrations of OH given in Fig. 1 may be too high by about a factor of 2. If valid, this analysis would require corresponding reduction in source strengths inferred for CS_2 and COS. Relative abundances of CS_2, COS and SO_2 in remote locations are comparatively insensitive to details of the chemical model for OH, and provide a useful test of the hypothesis proposed here, that is, that oxidation of CS_2 and COS might represent dominant background sources of SO_2. Our model predicts concentration ratios CS_2:COS:SO_2 at 6 km, of 0.3:1.0:0.13 which may be compared with observed ratios[4] of 0.44:1.0:0.17. This is a fairly good agreement, when one remembers that the observational data for COS and SO_2 are uncertain to within about ±30%, that our value for the concentration of CS_2 was inferred from measurements of dissolved CS_2, and that the temperature dependencies of the rate constants for the key reactions (1), (4) and (8) are not well defined. In our model, one-half of the SO_2 source is derived from oxidation of CS_2, for which observational data are extremely limited. The mixing ratio for COS is fairly well defined and, given the uncertainties in the rate constants for reactions (1), (3) and (4), oxidation of COS alone might provide the major source for background SO_2.

Results and discussion

Calculated height profiles for SO_2 are shown in Fig. 2, which includes comparison with the observations by Maroulis *et al.*[4] and Nguyen Ba Cuong *et al.*[20]. We define a standard model, *S*, characterised by rate constants and parameters summarised in Table 1. Our choice of rate constant for reaction (1) is based on data reported by Castleman *et al.*[21] and Cox[22]. In their studies the rate for reaction (1) was measured relative to the rate for reaction of OH with CO. We applied suitable correction to account for the known pressure dependence[23] of OH+CO.

Our standard model assumes that the rate for reaction (1) is independent of temperature. Dependence of results on choice of rate expressions for reaction (1) is shown in Fig. 2*a*, which also includes models allowing modest negative activation energies

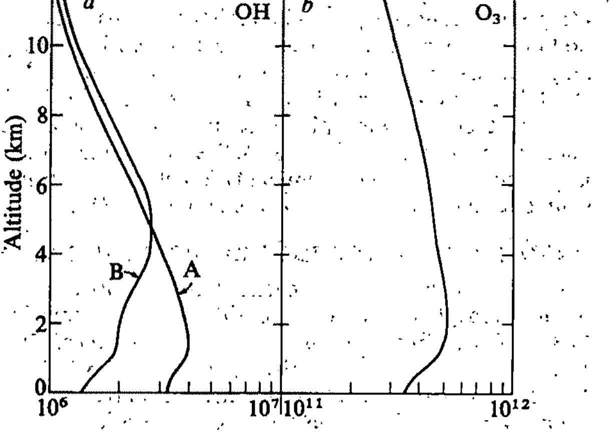

Fig. 2 Altitude profiles for SO_2 at 15° S latitude at equinox. The profiles were calculated with the model given in Fig. 1, curve B. The curves labelled S used the standard chemical model of Table 1, with a deposition velocity for SO_2 of 1 cm s^{-1} and a zero-flux boundary condition at the tropopause. The COS mixing ratio was specified at 0.5 p.p.b. Data are from Maroulis *et al.*[4] (●), aircraft flight over the Pacific Ocean, 0–67° S); and Nguyen Ba Cuong *et al.*[20] (x), Indian Ocean cruise, 5–25° S). *a*, The effect of temperature dependent rate constants: curve A, k_b $(OH+SO_2)=5.7\times10^{-33}$ exp (1,000/*T*); curve B, $k_4=3.4\times10^{-14}$ exp (150/*T*), $k_8=1.1\times10^{-13}$ exp (150/*T*). *b*, Uses the standard model *S*, but with values for the deposition velocity for SO_2 equal to 2.0, 0.4 and 0.1 cm s^{-1} as noted. *c*, The dashed curve includes loss of SO_2 to aerosols, with a sticking efficiency of 10^{-3}, as described in the text. *d*, The effect of a source of SO_2 from oxidation of DMS. Curve C includes an ocean source of DMS of 2.5 Mtonnes S yr^{-1}, in addition to SO_2 sources from CS_2 and COS oxidation, and may be considered as our best model. The curve labelled 'DMS only' omits all sources of SO_2 except that from DMS oxidation, and allows for a DMS source of 25 Mtonnes S yr^{-1}, the value suggested recently by Nguyen Ba Cuong *et al.*[37]. The calculated profiles of SO_2 exhibit small (<15%) variations with latitude between 45° N and 45° S.

for reactions (4) and (8). It seems probable that rates for reactions (4) and (8) should be faster at low temperature, given the reaction mechanism proposed by Kurylo[6,24]. The temperature dependence of k_1 is poorly determined. The rate expression given in Fig. 2*a* was based on preliminary work by Castleman and Tang[25] and Erler *et al.* (ref. 26 and results in ref. 10).

Figure 2*b* shows the dependence of calculated profiles for SO_2 on the choice of deposition velocity, while Fig. 2*c* shows the possible influence of heterogeneous loss due to aerosols. The general behaviour of the profiles in Fig. 2*a–c* is similar. In all cases we find higher mixing ratios at high altitude, consistent with the observational data of Georgii *et al.*[27] and Maroulis *et al.*[4]. Uncertainties in loss processes tend to affect mainly concentrations computed for the lowest altitudes. Deposition velocities over land[8] are reported in the range 0.1–2.0 cm s^{-1} while Hicks and Liss[28] suggest that a value of about 1 cm s^{-1} should be appropriate for moderate wind conditions at sea.

Results in Fig. 2*c* imply that loss of SO_2 to aerosols should be relatively unimportant, at least in the marine atmosphere. We used an integrated surface area for aerosols equivalent to 1×10^{-7} cm^2 per cm^3, an estimate based on particle size distributions measured by Meszaros and Vissy[29], Blifford[30], and Jaenicke *et al.*[31]. We investigated sticking efficiencies for SO_2 as high as 10^{-3}, although experimental data[32] suggest efficiencies much lower than this, in the range 10^{-3}–10^{-6}. Results in Fig. 2 do not allow for transient reductions in SO_2 which might arise due to rainfall.

We assumed a rate constant for reaction (3) equal to 10^{-15} $\text{cm}^3\ \text{s}^{-1}$. With this choice, reaction (3) represents a relatively minor sink for SO_2. Measurements by Kan *et al.*[33] indicate removal of CH_3O_2 by SO_2, with an effective rate constant of $5\text{–}10 \times 10^{-15}$ $\text{cm}^3\ \text{s}^{-1}$. If loss of CH_3O_2 observed in the laboratory is associated with the reaction channel (3), concentrations in Fig. 2 could be reduced by about 20%. This estimate assumes, however, an unproven model for oxidation of atmospheric CH_4. It seems unlikely that k_3 should be as large as 10^{-14} $\text{cm}^3\ \text{s}^{-1}$ given the much smaller value, $\leq 10^{-17}$ $\text{cm}^3\ \text{s}^{-1}$ (refs 34, 58), reported for the analogous reaction (2).

Oxidation of DMS could provide an additional source of SO_2 as suggested by Lovelock[35] and discussed further by Maroulis and Bandy[36] and Nguyen Ba Cuong *et al.*[37]. The associated source of SO_2 would be confined to the lowest 2 km of the atmosphere as the reaction of DMS with OH is exceedingly rapid[38]. Thus DMS cannot account for the height profile observed for SO_2, a point shown in Fig. 2*d*. Similar arguments apply to the suggestion that oxidation of H_2S might produce a large source of SO_2. Hydrogen sulphide also reacts very rapidly with OH[39], and concentrations as low as a few parts per trillion have been observed in tropical marine air[40]. Most estimates of the contribution of H_2S to the atmospheric sulphur cycle have been derived by subtracting other terms in the budget for sulphur, and are consequently highly uncertain[1,2]. While biogenic sources of H_2S and DMS may provide significant contributions to the atmospheric sulphur cycle in selected environments (for example, near swamps or salt marshes), these sources cannot account for the observations of SO_2 discussed here.

Liss and Slater[41], using measurements by Lovelock *et al.*[35], estimate a net source of 3.7 Mtonnes S yr^{-1} associated with release of marine DMS, a source whose magnitude should be reduced by about a factor of 1.5 to account for more recent estimates of rates for gas exchange across the air–sea interface[42].

It seems probable that the concentrations of atmospheric CS_2 and COS should reflect a combination of biogenic and industrial sources[43,44]. Preliminary measurements of the emission rates of sulphurous gases over salt marshes have shown that fluxes of COS might be comparable to, and in some cases greater than fluxes of H_2S[45]. The relatively uniform distribution[4,13,46,47] observed for COS suggests a globally distributed source. This apparently argues against a significant industrial component, although there might be important production due to forest fires and combustion associated with land clearance for agriculture. The possibility of a dominant industrial component for CS_2 cannot be excluded, given limitations in the present data base. It seems more likely, however, that diffuse sources should dominate for CS_2 as well as for COS. These sources may include a component due to combustion although thermodynamic considerations suggest that reactions in reducing environments may be more important. It seems probable that these reactions should be microbially mediated: swamps, anaerobic muds and the digestive tracts of various animals offer plausible sites. The relatively uniform distribution observed for SO_2 in the upper marine troposphere[4] requires a diffuse atmospheric source for

Table 1 Kinetic data

* Units $\text{cm}^3\ \text{s}^{-1}$ for bimolecular reactions; $\text{cm}^6\ \text{s}^{-1}$ for termolecular reactions. The complete chemical scheme is described in Logan *et al.*[13].

† The integrated surface area for marine aerosols was taken to be 1.0×10^{-7} cm^2 per cm^3, and a scale height for the aerosol distribution function of 1 km was adopted (see refs 29–31).

this gas. Oxidation of COS and perhaps CS$_2$ as discussed here can provide a relatively straightforward explanation for the existence of a uniform background level of SO$_2$.

The effects of past variations of the Earth's rotation rate on climate

B. G. Hunt

Australian Numerical Meteorology Research Centre, PO Box 5089AA, Melbourne, Australia 3001

Palaeological evidence indicates that the rotation rate of the Earth during the late Precambrian was 2–2.5 times faster than now. Typically high rotation rate in a fluid system reduces the characteristic size of dynamic features, their associated transport processes and the overall intensity of the motions. The climatic consequences of the high rotation rate during the Precambrian are outlined. In particular, it is hypothesised that variations in the rotation rate imposed an important, and possibly dominant, effect on the genesis and termination of the Precambrian ice age. Other possible implications of the high rotation rate to oceanography, life forms and geology are briefly noted.

POTENTIAL mechanisms for producing climatic variations include solar perturbations owing to orbital variations of the Earth[1], volcanic activity[2], tectonic movements[3], fluctuations in solar output[4], glacier surgings[5] and oceanic feedback[6]. On a time scale of hundreds of millions of years a further factor, which has received relatively little attention[7], is the increase in the rotational period of the Earth. This increase is very small ($\sim$2.5 ms per century) and is still taking place. However, since the atmospheric and oceanic circulations are known to be critically influenced by the Earth's rotation rate it follows that climate should also be affected. Hence it is of value to consider what impact past variations in the rotation rate might have had on the evolution of the Earth's palaeoclimate, and to see how well the deductions fit the known facts.

This assessment will be obtained by interpreting the results of a numerical model of the atmospheric circulation. This general circulation model of the atmosphere was hemispheric in extent, devoid of topography and thus oceanic influences, and was set up for fixed annual mean conditions[8]. Despite these apparently serious omissions the model is capable of a remarkable simulation of many features of the atmosphere[8,9], which encourages the belief that its application to problems concerned with variations in the rotation rate of the Earth has merit. This model has now also been run with the rotation rate increased and decreased by a factor of 5 as part of a spearate study[10], and it is this data base of three experiments which will be used here.

Prehistorical perspective

The rotational history of the Earth can be traced back to the late Precambrian era, about 1.5×10^9 yr ago. Based on growth patterns from shells and corals the Earth then had at least 800–900 solar days per yr, implying a rotation rate 2–2.5 times greater than the present value[11]. MacDonald [12] has calculated the past variation of the rotation rate and his results for one set of assumptions are shown in Fig. 1. This illustrates a possible increase in rotation rate with decreasing time up to about

0028–0836/79/380188—04$01.00

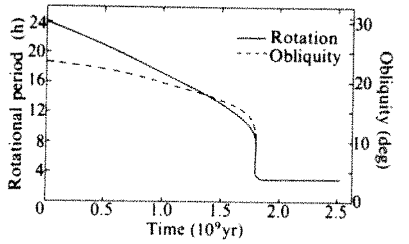

Fig. 1 Variation with time of Earth's rotational period (left-hand scale) and obliquity (right-hand scale).

1.7×10^9 yr ago, when a discontinuity associated with the closest approach of the Moon to the Earth may have occurred. Such a discontinuity, if real, would have created catastrophic climatic and other changes. Consequently the emphasis here will be placed on the less dramatic, but continuous, climatic effects associated with the subsequent steady decrease of the rotation rate between 1.7×10^9 yr ago and the present.

It is also necessary to consider other factors which may have been important to climatic evolution in this time frame in order to clarify the contribution from rotation rate variations. Thus continental drift, as recently reconstructed by Irving [13] back to the middle Devonian (375×10^6 yr ago), could markedly affect climate. This can occur via continentality effects associated with large land masses[14], or through changes to ocean depths or basin sizes[15]. In particular shallower oceans would have had a less ameliorating influence on climatic developments. (Note that rotation rate variations would also have affected the dynamics of the motions in the molten interior of the Earth, and therefore geomagnetic activity, in addition to the motions of the atmosphere and oceans. Presumably such dynamic variations could have influenced the large-scale convective motions responsible for tectonic activity and volcanism, and this could be an important factor in the geological evolution of the Earth.) A further prehistorical factor is the change in the obliquity of the Earth's Equator to the ecliptic associated with the dynamics of the Earth–Moon system (Fig. 1). The lower obliquity in the past implies less annual mean solar input to high latitudes and therefore possibly colder polar regions, all else being the same. The luminosity of the Sun has also probably increased with time; a 25% increase over the past 4.5×10^9 years has been suggested[16]. Wetherald and Manabe[17] have shown that 1–2% variations in the solar constant could have significant effects on the climate of a general circulation model, particularly at high latitudes. Composition changes in the atmosphere during its evolution are also relevant, and contribute to a computed 10 K increase in mean surface temperature over the past 1.5×10^9 yr (ref. 16). The principal change in composition during this time span is supposedly in the O_2/N_2 ratio. A further important factor in climatic variability is volcanic activity[2]. Other forcing functions could be enumerated but not all of these are relevant to the time frame of interest here. The above list is thought to contain the principal precursors of climatic change which should be considered simultaneously with an evaluation of the contribution associated with the decrease in the Earth's rotation rate.

Model climatology at high rotation rate

A summary of the results of the general circulation model run with a fivefold increase in rotation rate[10] is given here to illustrate the markedly different atmospheric behaviour in these conditions. For simplicity this model was run with all radiative terms (including cloud cover, surface albedo and CO_2 amount) set at current values. These and other model parameterisations are based on present atmospheric conditions which would not necessarily apply in the extreme conditions considered here. This undoubtedly distorted the details of the results but the dynamically induced changes in the large scale circulation are reasonably realistic.

An important difference is shown in Fig. 2, where a comparison of near surface (0.9 km) synoptic meridional velocity distributions for this model and the control (normal rotation rate) reveals a distinct reduction in scale size at high rotation rate. Wavenumber 13 predominates compared to wavenumber 6 for the control. This result is not resolution limited[18], and in fact the overall behaviour of the model at all three rotation rates closely resembled the general flow characteristics produced by laboratory analogues of the atmosphere in appropriate conditions[19,20]. A consequence of the smaller scale size was that the synoptic distributions of the various atmospheric fields (velocity, temperature, moisture) were poorly correlated. This resulted in a reduced tropospheric polewards transport of sensible and

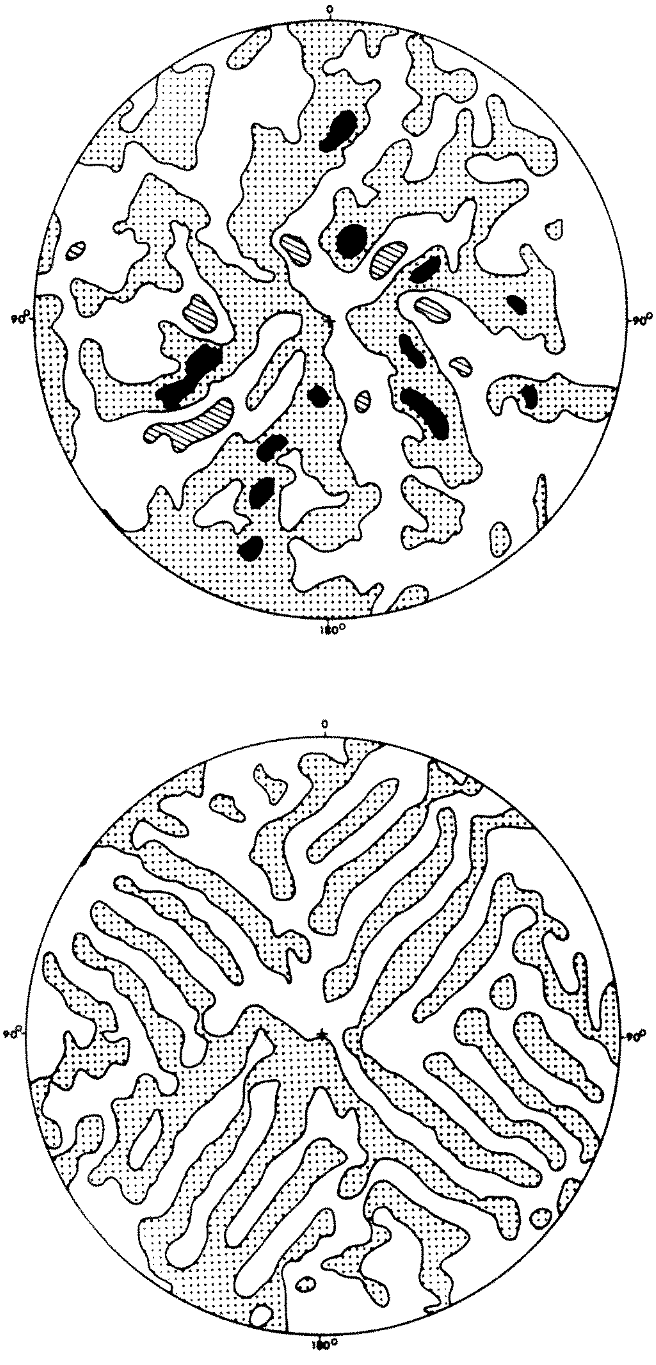

Fig. 2 Instantaneous synoptic meridional (north–south) velocity distributions for normal rotation and fivefold rotation rates are given in top and bottom of figure respectively. The circumscribing circle is the Equator, the + sign the Pole. Solid areas, $>10\ \mathrm{m\ s^{-1}}$; stippled, $0\text{–}10\ \mathrm{m\ s^{-1}}$; blank, $0\text{–}(-10)\ \mathrm{m\ s^{-1}}$; cross-hatched, $>-10\ \mathrm{m\ s^{-1}}$.

latent heat by the dominant large-scale eddies, thus causing a much colder high latitude region and a warmer tropics.

The mean meridional stream function increased from three to five cells, with the tropical Hadley cell being markedly reduced in latitudinal extent and intensity. The mean zonal winds were almost halved in intensity, with the tropospheric westerly jet stream being located at 10° latitude. The stratospheric westerly jet virtually ceased to exist as a separate entity. A simple application of the thermal wind equation suggests that a more intense tropospheric jet should have been obtained because of the increased tropospheric latitudinal temperature gradient in the model. However, this equation is invalid at fast rotation rates where motions are highly ageostrophic, and again the model's behaviour is confirmed by laboratory analogue experiments[19,20].

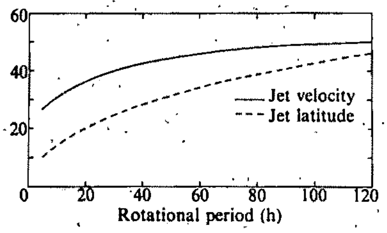

Fig. 3 Variation with Earth's rotational period of the intensity of the mean zonal wind ($m\,s^{-1}$) of the tropospheric jet, and of the location of the jet (deg latitude).

The conventionally defined arid region of the globe narrowed in latitudinal extent and moved towards the Equator, but most of the globe polewards of 45° also became semi-arid as the increased coldness of the troposphere caused a general decline in evaporation and precipitation in this region.

Implications of rotation rate variations for Earth's climate

Consider first the overall impact of the change in wind strength with rotation rate as derived from the three model experiments. This is illustrated in Fig. 3 by the variation of the intensity and latitude of the tropospheric jet stream, which is located at a height of about 10 km. This indicates that for a rotational period of 9 h (late Precambrian era) the jet stream intensity was reduced by about 20% compared to its current value, but, more importantly, the jet was located much closer to the Equator at 15° latitude. As illustrated in Fig. 1 of ref. 10 the confinement of the jet to low latitudes was associated with a reduction in the overall intensity of the zonal winds in the troposphere as a whole, to a much greater extent than that implied by the 20% reduction in jet intensity. A prime consequence of this constraint is that in Precambrian times the surface wind stress, which is normally proportional to the square of the wind velocity, would have been reduced by possibly as much as a factor of 2. A rough indication of this change can be obtained by comparing the intensity and variability of the near surface synoptic wind distributions in Fig. 2.

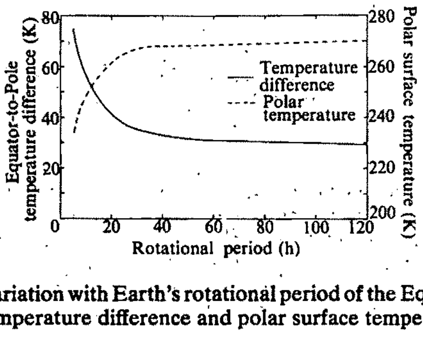

Fig. 4 Variation with Earth's rotational period of the Equator-to-Pole temperature difference and polar surface temperature.

Perhaps the single most important effect of the reduced surface stress would have been its impact on the oceans. For example there would have been less wind-induced vertical mixing in the ocean, resulting in a shallower, warmer mixed layer, in general, with presumably a smaller overall heat capacity. A smaller heat capacity would make the oceans less able to reduce the amplitude of seasonal and interannual fluctuations of ocean sea surface temperature, which are important in determining the behaviour of the atmosphere[21]. In addition the scales of motion in the ocean would have been reduced by the higher rotation rate of the Earth, which, together with the lower stress, should have weakened the strength of the oceanic gyres. This would also have decreased the amount of heat transported polewards by the oceans, the latter being a significant component of the total polewards flux of energy[22]. The net effect of all these changes should be to produce a general warming of the tropical oceans and atmosphere and a colder polar region, possibly associated with greater transient departures from mean conditions. The smaller obliquity of the Earth (Fig. 1) might also have complemented these rotationally induced variations.

An additional oceanographic effect to be expected under Precambrian rotational conditions is a reduction in upwelling (depending on continental configurations) and therefore in the supply of nutrients to surface layers. This would have discouraged biological activity and may have some implications to metazoan evolution[23].

All of the above comments should be qualified by noting the tremendous changes which have occurred in oceanic basins during geological history[13]. Some of these changes may well have ameliorated the purely rotational aspects considered here.

A further aspect of the lower wind stress at higher rotation rate concerns atmospheric composition. Transfer of gases between atmosphere and surface would have been restricted, as would, presumably, vertical transport in the troposphere. In addition, the enhanced coldness and aridity at high latitudes would have reduced biological activity, which is crucial to the production of minor, but important, atmospheric constituents such as N_2O, NH_3 and CH_4. Such subtle effects may have influenced the overall development of atmospheric composition, notably that of O_3 which is considered to be a vital constituent in the development of life on land because of its UV screening efficiency[24].

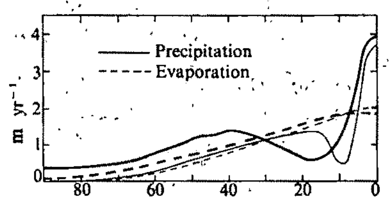

Fig. 5. Comparison of time averaged zonal mean precipitation and evaporation rates for normal rotation (thick lines) and fivefold rotation rates (thin lines).

The net consequence of the reduced polewards heat fluxes suggested by the model for Precambrian times is a colder polar region and an enhanced Equator-to-Pole temperature difference as shown in Fig. 4. A 20 K colder pole is indicated for a rotational period of 9 h, unless the polar cloud cover and thickness were different. The latter may well have been the case given the reduced water vapour content of the colder atmosphere and the smaller-scale systems. Certainly Hart's[16] global mean calculations suggest an overall cloud cover of only ~30% at this time in conjunction with a mean surface temperature of 280 K. This temperature is over 10 K colder than that of the fast rotation rate general circulation model, perhaps indicating that simple comparisons between the two approaches are not meaningful.

Although the model implies that the precipitation rate was very small at high latitudes during the Precambrian era (see Fig. 5), conditions should have been conducive to the accumulation of ice cover, depending on the dispositions of the continent(s?)[14]. On this basis it can be hypothesised that glacial conditions prevailed throughout the Precambrian, and solely because of rotational considerations! The extent of the ice cover would have declined continuously, all else being equal, as the Earth's rotation rate decreased and the improved circulation systems warmed high latitudes. This explanation can also reasonably account for the termination of the Precambrian ice age 6×10^8 yr ago, when the rotational period of the Earth would have been 20 h and thus dynamical conditions less conducive to the maintenance of glaciation. The occurrence of the Permo-Carboniferous ice age ($\sim3\times10^8$ yr ago) and the present Quaternary ice age are somewhat paradoxical, especially when the assumed increase of the solar output[16] is taken into consideration. Continental drift, volcanic activity and so on may play some part but other unknown factors seem to be important. For example, energy budget studies indicate that in present conditions an ice-free Arctic Ocean would be self-sustaining[25], thus raising the problem of the initial cause of the glaciation.

In Fig. 5 the zonal mean evaporation and precipitation rates for the fast and control models are compared. Interpolating results to Precambrian conditions indicates that equatorial conditions were similar to those of today but that the adjacent zone of high aridity was narrower and closer to the Equator. The general aridity and/or coldness at higher latitudes implied by Figs 4 and 5 suggests a rather harsh climate unattractive to all but the hardiest life-forms at that time. Higher latitudes would have become progressively habitable as the Earth's rotation rate slowed, but the subtropical very arid zone would have expanded. Because of the smaller-scale and less organised nature of meteorological systems suggested for the Precambrian, precipitation generally would have been less intense and more localised. This means that run-off and erosion would have been lower and this could have some relevance to the interpretation of, say, alluvial deposits.

Although the above discussion of Precambrian conditions is necessarily speculative, certain features can be viewed with some confidence. Among these are the delineation of climatic zones in Fig. 5, and the jet stream variations of Fig. 3, both of which are closely associated with the requirements for conservation of absolute angular momentum in the Earth–atmosphere system. Similarly the small scale size of dynamical features is a well established characteristic of high rotation rate[19,20]. Thus, although distortion of the model results could possibly have arisen from inadequacies of the radiative scheme used, grossly different results should not be expected.

Finally, since a general appreciation of the past variation of the Earth's rotation rate appears to be lacking, it might be useful to reinterpret data from several other disciplines where rotational effects could prove to be of importance.

Single strands induce recA protein to unwind duplex DNA for homologous pairing

Richard P. Cunningham, Takehiko Shibata, Chanchal DasGupta & Charles M. Radding

The Departments of Internal Medicine, and Molecular Biophysics and Biochemistry, Yale University School of Medicine, New Haven, Connecticut 06510

Single-stranded DNA, whether homologous or not, stimulates purified Escherichia coli *recA protein to unwind duplex DNA. This helps to explain how recA promotes a search for homology in genetic recombination. As oligodeoxynucleotides also stimulate unwinding, a common mechanism may relate the function of recA protein in recombination to other functions (SOS) induced by oligonucleotides.*

BECAUSE breakage of DNA by various means stimulates general genetic recombination, some investigators have suggested that recombination begins with the interaction of a single strand with duplex DNA (see ref. 1 for review). As a model for this kind of interaction, Holloman *et al.*[2] and Beattie *et al.*[3] studied the uptake of homologous single strands by superhelical DNA [replicative form I (RFI) or form I], a reaction that produces a D-loop (see Fig. 1). By transfection of *Escherichia coli*, Holloman and C.M.R.[5] implicated the *recA* gene in the homologous interaction of a single-stranded fragment with superhelical DNA. More recently, Shibata *et al.*[4] observed that stoichiometric amounts of highly purified recA protein promoted the rapid formation of D-loops by superhelical DNA and homologous single-stranded fragments (Fig. 1).

The properties of the uncatalysed formation of D-loops, which occurred rapidly only at non-physiological temperatures,

0028–0836/79/380191—05$01.00

suggested that the rate was limited by the initial unstacking of a small number of base pairs in superhelical DNA[3]. As recA protein bypassed this rate-limiting step, we suggested that it acted in part by unstacking base pairs in duplex DNA. We also observed that a preparation of nicked circular DNA (form II) was one-third as active as superhelical DNA in forming complexes with single-stranded fragments[4]. Subsequently, we have confirmed that form II DNA is a substrate for the formation of D-loops by recA protein (see below). The latter observation strengthened the inference that recA protein has an unstacking or unwinding activity, which is the subject of this article.

Unwinding of duplex DNA by recA protein in the presence of ATPγS and single strands

To obtain direct evidence that recA protein unwinds DNA, we incubated it with fd form II DNA, added DNA ligase, and examined the product by gel electrophoresis and isopycnic centrifugation in CsCl plus propidium diiodide[6,7].

In the absence of recA protein, ligase sealed more than half of the form II DNA as indicated by gel electrophoresis (Fig. 2*a*, *b*) and by the assay of Kuhnlein *et al.*[8] for covalently closed DNA. At the ionic strength of the gel, these covalently closed molecules (form I') migrated as a set of bands of positively superhelical DNA, which overlapped a band due to linear DNA (form III) present in the preparation (Fig. 2*b*). When recA protein and adenosine 5'-*O*-(3-thiotriphosphate) (ATPγS) were incubated with form II DNA before ligation, the observed distribution of products was similar; ligase worked well but there was no apparent change in the average linking number of the population of sealed molecules (Fig. 2*c*). However, when we added fragments of single-stranded ΦX174 DNA during the incubation with recA protein, we observed a very different result. Ligase still closed about one-third to one-half of the fd form II DNA, but all the closed DNA migrated as a single band of more compact DNA, at about the position of form I (Fig. 2*d*). In three experiments, when recA protein and ATPγS were incubated with form II DNA in the absence of any added single-stranded DNA before ligation, we observed the formation of a small amount of material with the electrophoretic mobility of form I (see Table 1, lines 1 and 2). Controls included the following variations of the mixture represented in Fig. 2*d*: no recA protein; no form II DNA; no ATPγS; ATP in place of ATPγS; recA protein in the absence of ligase (Fig. 2*a*). In no case was DNA detected in the position of the rapidly migrating band.

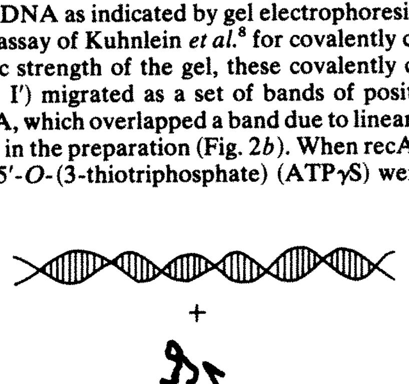

Fig. 1 The formation of a D-loop catalysed by recA protein[4]. The actions of recA protein apparently include (1) unwinding double-stranded DNA, (2) unfolding single-stranded DNA, (3) homologous pairing, and (4) uptake of a single strand rather than rewinding of the original duplex DNA.

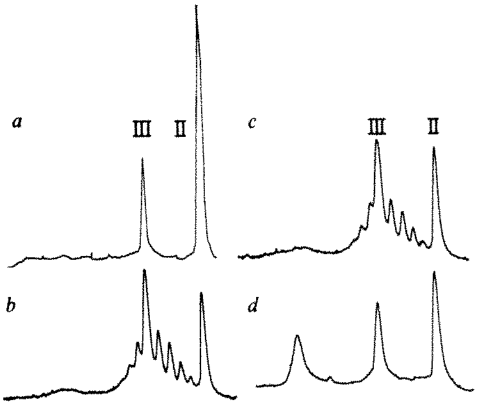

Fig. 2 The linking number of circular DNA sealed in the presence of recA protein and ATPγS (Boehringer-Mannheim). Microdensitometer tracings of electrophoretic gels prepared as described in Fig. 4, legend. *a*, Control, fd form II DNA incubated with recA protein but no ligase. The preparation of DNA contained about 30% form III DNA as indicated. *b*, Ligase only (New England BioLabs). *c*, Ligase plus recA protein. *d*, Ligase, recA protein and 12-μM fragments of heterologous single-stranded DNA from ΦX174. The various forms of circular DNA from phages ΦX174 and fd were prepared as cited previously[4]. Single-stranded fragments were prepared by boiling 840 μM DNA for 15 min in 0.1 mM EDTA and 10 mM Tris-HCl at *p*H 7.5. All concentrations of DNA are expressed as mol of nucleotide. The reaction mixture was the same as that described in Table 2 legend, except that heterologous single-stranded fragments were substituted for homologous fragments, the volume was doubled and ATP was replaced by 0.5 mM ATPγS. After incubation at 37 °C for 30 min, the mixture was chilled on ice, KCl, $(NH_4)_2SO_4$ and NAD^+ added to make their concentrations 25 mM, 10 mM, and 25 μM, respectively, and incubated at 18 °C for 5 min. 0.3 units of *E. coli* DNA ligase were then added and the sample, 50 μl total volume, incubated for 90 min. The reaction was stopped by adding EDTA, 28 mM, and SDS, 0.17%. The sample was transferred to a bath at 37 °C, proteinase K, 0.2 mg ml^{-1} added and the sample incubated for 15 more minutes.

To determine whether the compact closed DNA had a lower or a higher linking number than the DNA closed by ligase alone (form I'), we centrifuged the products of a similar experiment in an isopycnic gradient of CsCl and propidium diiodide (Fig. 3 and Table 1). In the absence of recA protein, half of the recovered DNA was found in a single peak at the dense end of the gradient, as expected for form I' DNA derived from the closure of form II by ligase (Fig. 3*b*, Table 1, line 1). Incubation of form II DNA with recA protein and ATPγS before ligation had little effect on the distribution (Fig. 3*a*, Table 1, line 2). However, when recA protein, fd form II DNA, ΦX174 single-stranded fragments and ATPγS were incubated before ligation, the peak of form I' DNA at the dense end of the gradient disappeared almost entirely and was replaced by DNA with a broad distribution of densities

Table 1 Unwinding of DNA

		Distribution (%)		
	Total recovery (%)	I'	Intermediate	II+III
Ligase only	22	46	4	50
+recA protein	29	39	7	54
+recA protein and fragments	28	8	21	71

Data tabulated from Fig. 3. The DNA labelled 'Intermediate' has a lower linking number than form I' DNA, the product of sealing by ligase alone.

between those of form I' and linear or form II DNA (Fig. 3*a*, Table 1, line 3), that is, DNA with lower linking numbers than form I'. The peak of material of intermediate density corresponded to the position of negatively superhelical fd DNA (form I DNA). The total recovery of radioactivity was similar in the three parts of this experiment; the fraction of closed circular DNA relative to linear or form II DNA (Fig. 3*a*, Table 1, line 1) was the same as that estimated by the assay of Kuhnlein *et al.*[8], which indicates that the distribution of recovered material was not biased.

Lack of topoisomerase activity of recA protein

The unwinding observed in the experiments described above could have occurred before or after ligation, but three experiments show that recA protein lacks detectable topoisomerase activity in the presence of either ATPγS or ATP. We incubated recA protein with relaxed closed circular DNA (form I') in conditions identical to those of the experiments shown in Figs 2 and 3, including a sample which contained heterologous fragments and ATPγS. When we observed the product by gel electrophoresis, we found no DNA in the position of form I DNA, and no perceptible shift in the distribution of form I' DNA (Fig. 4). With the following additions or omissions, we examined, by gel electrophoresis, the fate of fd RFI incubated for 30 min at 37 °C with recA protein and fragments of single-stranded ΦX174 DNA: ATP; ATPγS; ATPγS without single-stranded fragments; ATPγS without recA protein. We observed little or no change in the amount of form I DNA (data not shown).

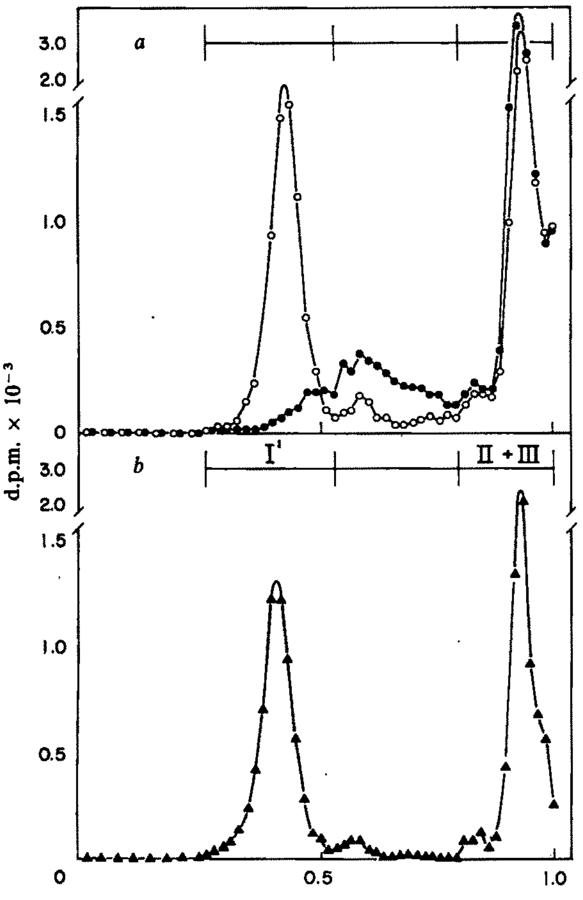

Fig. 3 Decreased linking number of circular DNA sealed in the presence of recA protein and ATPγS; isopycnic centrifugation in CsCl and propidium diiodide[7]. *a*, fd form II DNA sealed in the presence of recA protein only (○), and in the presence of recA protein plus heterologous fragments of single-stranded DNA from ΦX174 (●). *b*, Control. DNA sealed in the absence of recA protein (▲). The left end of the figure corresponds to the dense end of the gradient. We summed values as indicated by the brackets (Table 1). All values were corrected for quenching. Solutions, 7.4 ml, contained CsCl to make the density 1.565 g cm^{-3}, 500 μg ml^{-1} propidium diiodide, 10 mM Tris-HCl and 1 mM EDTA at *p*H 8.0. These solutions were centrifuged at 44,000 r.p.m. and 20 °C for 69 h in a Beckman 75ti rotor. The resulting gradients were collected from the bottom of the tube and counted in a scintillation fluor containing Triton X-100.

In further experiments we made D-loops by incubating recA protein with fd form I DNA and fragments of fd single strands in the presence of ATP[4]. Measurement by electron microscopy of 22 D-loops with one or two single-stranded tails showed that the mean length was 416±45 nucleotides. (We were unable to distinguish the double-stranded arm of the D-loop from the single-stranded one. As there was little difference in the lengths of the two arms of any D-loop, we simply measured both and calculated the average of all values.) In the conditions of the reaction, fd form I DNA should contain about 40 superhelical turns which corresponds to a D-loop about 400 nucleotides long. Previous observations have shown a rough equivalence between the length of D-loops measured by electron microscopy and the length predicted from the superhelix density in solution[9]. Observation of the same relationship in these experiments suggests that when recA protein catalysed the formation of D-loops from form I DNA, the linking number of the closed circular DNA was not markedly changed.

Table 2 Homologous pairing of double-stranded DNA and single-stranded fragments

Fragments	% fd double-stranded [^{3}H]DNA retained	
	form I	form II
None	1	4
fd	34	22
ΦX	2	6

The reaction mixture, 20.5 μl in volume, contained 31 mM Tris-HCl at *p*H 7.5, 25 mM $MgCl_2$, 1.8 mM dithiothreitol, 88 μg ml^{-1} bovine serum albumin, 1.3 mM ATP, 8.8 μM RF[^{3}H]DNA, 12 μM single-stranded DNA fragments and 98 μg ml^{-1} recA protein[4]. The mixture was incubated at 37 °C for 30 min, chilled and 18 μl transferred to 0.5 ml of cold 25 mM EDTA. Aliquots were taken from this mixture to measure total counts, D-loops and closed circular DNA, exactly as described before[4].

Nature of the cofactor for unwinding by recA protein

Unwinding is supported either by heterologous or homologous single-stranded fragments (Fig. 4*a*, *b*). Circular single-stranded DNA, which does not form D-loops, promoted unwinding (Fig. 4*d*). Double-stranded restriction fragments were inactive, but their boiled products were active (Fig. 4*f*, *g*). This observation indicates that the cofactor was not some fortuitous ingredient of the DNA preparations. A digest, consisting entirely of acid-soluble material produced by treatment with pancreatic DNase and boiling, also supported the unwinding activity very well (Fig. 4*e*). The following, added singly, promoted little or no unwinding: deoxyadenosine, dAMP, dGMP, dCMP, dTMP, AMP and CMP (data not shown).

Homologous pairing of form II DNA and single-stranded fragments

Table 2 compares form II and form I DNA as substrates for recA protein in the homologous pairing with single-stranded

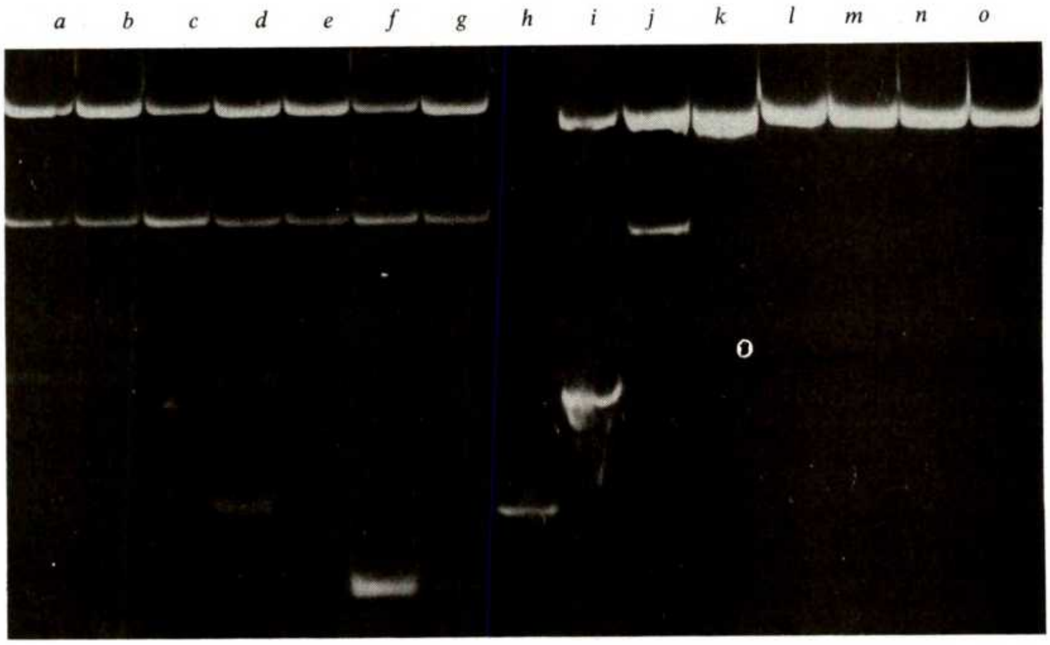

Fig. 4 Nature of the cofactor that stimulates unwinding by recA protein in the presence of ATPγS (*a–g*); absence of topoisomerase activity in recA protein (*l–o*): agarose gel electrophoresis. Lanes *a–g* contained fd form II DNA sealed in the presence of recA protein, ATPγS and 12 μM DNA cofactors: *a*, fragments of single-stranded ΦX174 DNA; *b* fragments of single-stranded fd DNA; *c*, no addition; *d*, fd phage DNA; *e*, boiled DNase I limit digest of ΦX174 RFI DNA; *f*, restriction endonuclease *Hae*III digest of fd RFI; *g*, the preceding digest boiled. Lanes *h–k* contained markers: *h*, fd phage DNA; *i*, fd RFI DNA; *j*, fd form II DNA (~70%) and fd form III DNA (~30%), *k*, fd form I' DNA. Lanes *l–o* contained fd form I' DNA incubated with recA protein and ATPγS: *l*, no addition; *m*, fragments of single-stranded ΦX174 DNA; *n*, preceding sample minus recA protein; *o*, fragments of single-stranded ΦX174 DNA plus ATP instead of ATPγS. To obtain the limit digest indicated above 24 μM ΦX174 RF DNA was treated with 20 μg ml^{-1} pancreatic DNase (Worthington) for 30 min at 37 °C in 5 mM $MgCl_2$ and 10 mM Tris-HCl at *p*H 7.5, which rendered all the DNA acid soluble. The product was boiled for 4 min to inactivate the pancreatic DNase and denature all the fragments. Nicked circular DNA, sealed by polynucleotide ligase was slightly positively superhelical under the conditions of gel electrophoresis (for example lane *c*) whereas closed circular DNA relaxed by calf thymus topoisomerase had a titrable superhelix density close to zero (for example lane *k*). We used 1% agarose gels, 16 cm × 16 cm × 0.3 cm in E buffer, which contained 40 mM Tris-acetate, 5 mM sodium acetate and 1 mM EDTA at *p*H 8.0. Current was applied at 35 V for 16–18 h, and the buffer was recirculated between the reservoirs, following which we stained the gels for 2 h in E buffer containing 0.5 μg ml^{-1} ethidium bromide. We illuminated the gels from below with a short-wavelength UV lamp (Ultra-Violet Products) and photographed them with Polaroid Tyffe 55 Land film. The negatives were scanned with a Joyce–Loebl recording micro-densitometer.

fragments. In the conditions of these experiments (see Table 2, legend), which differ slightly from previously described conditions[4], the preparation of form II DNA was one-half to two-thirds as active as form I DNA in making complexes that were retained by nitrocellulose filters. As the preparation of form II DNA contained less than a few per cent of form I DNA, these complexes must have been made with DNA that was not superhelical. The synthesis of complexes with form II DNA required homologous single-stranded fragments, and the properties of the product were similar to those of D-loops made from RFI; the complexes were not dissociated by treatment with 0.2% SDS nor by heating at 50 °C for 4 min in 1.5 M NaCl and 0.15 M Na citrate at *p*H 7. Preliminary electron microscopic observations suggest that a significant fraction of complexes made with form II DNA contain D-loops (data not shown). Recently, McEntee, Weinstock and Lehman also described the synthesis of D-loops from non-superhelical DNA, in that case, from linear phage P22 DNA[10].

The formation of D-loops by form II DNA suggests that recA protein unwinds DNA in the presence of ATP as well as in the presence of the analogue, ATPγS.

Discussion

Other experiments have shown that ATPγS competitively inhibits the ATPase activity of recA protein and blocks the formation of D-loops, but promotes the formation of complexes of protein, double-stranded DNA and single-stranded DNA (unpublished observations). The competitive inhibition shows that ATPγS occupies the same binding site as ATP; this, together with the other observations cited, suggests that the accumulation of partially unwound molecules reflects a step in the reaction that normally produces a D-loop. These effects of ATPγS on recA protein are reminiscent of observations on DNA gyrase which also catalyses several partial reactions in the presence of another non-hydrolysable analogue of ATP[11]. From the observed synthesis of D-loops with form II DNA, we infer that recA protein also unwinds DNA in the presence of ATP. The hydrolysis of ATP alters or dissociates the protein–DNA complex and accounts for the failure of partially unwound molecules to accumulate in the presence of ATP and DNA ligase (unpublished observations).

At first glance, the activation of unwinding by heterologous single strands seems incongruous for a mechanism that promotes homologous pairing, but further thought suggests that the opposite is true, that nonspecific stimulation of unwinding by any single strand explains in part how recA protein promotes a search for homology. As recombination in *E. coli* depends strongly on the function of recA[12], the action of recA protein by this mechanism implies that recombination often begins with the interaction of a single strand with duplex DNA.

Mutants of recA are pleiotropic, they affect not only recombination, but also a set of inducible functions, the so-called SOS functions[13]; these include error-prone repair, inactivation of phage repressors and the synthesis of recA protein itself (for reviews see refs 14, 15). Damaged DNA or blocked replication are inducing stimuli, and oligonucleotides have been implicated as intermediates in the induction[16,17]. The *tif*-1 mutation, which is located in the *recA* structural gene, makes the synthesis of recA protein thermo-inducible[18-22], indicating that a suitable form of the protein stimulates its own synthesis. The interaction of oligonucleotides with wild-type protein presumably stimulates synthesis by the same mechanism. However, observations on the *tsl* mutation indicate that abundant synthesis of recA protein may not be sufficient to induce fully all of the SOS functions[19,23]. Do oligonucleotides have a direct role in the inducible functions? Roberts *et al.* have studied one of the SOS functions *in vitro*, namely the inactivation of λ repressor by proteolytic cleavage[24,25]. In spite of the difficulty of reconciling proteolysis and unwinding of DNA, there are marked similarities between our observations on the unwinding of DNA by wild-type recA protein and those of Roberts *et al.* on inactivation of λ repressor by *tif* recA protein. Both processes require ATP or ATPγS, and oligonucleotide or single-stranded polynucleotide. The experiments described in this article show that both oligonucleotides and single-stranded DNA affect the functional properties of recA protein. The stimulation of unwinding by oligonucleotides, as well as by single strands, suggests that a common mechanism relates the function of recA protein in recombination to the other functions that are induced by oligonucleotides. Accordingly, oligonucleotides or single strands may trigger a conformational change of recA protein that can both unwind DNA and alter the interaction of recA protein with certain other proteins that bind to DNA.

A further inference from the similar effect of single strands and oligonucleotides on recA protein is that recombination may be inducible to some extent. Induction of synthesis of recA protein by single strands would provide the requisite amounts of protein to form D-loops, amounts which are large *in vitro*[4]. On the other hand, the induction of recA protein synthesis by oligonucleotides would not necessarily produce an increase in the number of genetic exchanges if any other factor, such as single strands, were limiting.

The *src* gene product of transformed and morphologically reverted ASV-infected mammalian cells

Morphological revertants of avian sarcoma virus transformed vole cells contain the sarcoma gene product (pp60^{src}) in an enzymatically active form, suggesting that the presence of pp60^{src} protein kinase activity is insufficient to induce morphological transformation. Structural analyses of pp60^{src} from infected vole cell clones suggest that in one of the revertant clones an alteration in pp60^{src} may be responsible for morphological reversion while in a second clone, reversion may result from an alteration in a cell gene product with which pp60^{src} must interact. As these morphological revertant cells are tumorigenic, different cell components are required to interact with pp60^{src} to facilitate the two events.

AVIAN SARCOMA VIRUSES (ASV) are able to induce tumours in birds and a variety of mammals as well as stably transform both avian and mammalian cells in culture. A single ASV gene, designated *src*, has been shown to be responsible for the induction and maintenance of cell transformation *in vitro* and tumour production in infected animals[1,2]. The ASV transforming or *src* gene product is a 60,000-molecular weight (MW) phosphoprotein (pp60^{src})[3-6] with an associated protein kinase activity, suggesting that ASV-induced neoplastic transformation may be the result of aberrant phosphorylation of cellular proteins by pp60^{src} (refs 6–8). In an attempt to elucidate the mechanism(s) by which the expression of this particular viral gene is regulated, and hopefully ultimately provide information concerning virus-induced oncogenesis, we have compared the products of the *src* gene in virus-transformed mammalian cells and morphologically normal revertant subclones of these cells. The cell system chosen for these studies was ASV-transformed

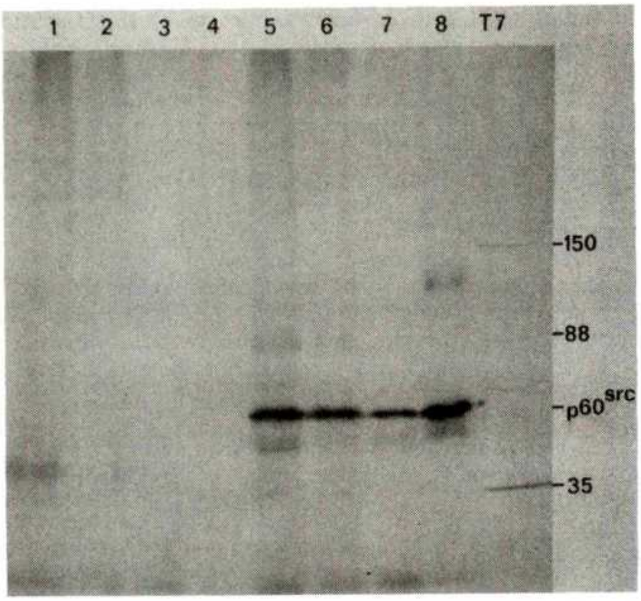

Fig. 1 Presence of phosphorylated pp60^{src} in transformed and revertant vole cells. Cultures were radiolabelled for 2 h with ^{32}P-orthophosphate (carrier-free (ICN), 0.5 mCi ml^{-1}). After cell lysis and clarification, cell extracts were immunoprecipitated with either normal rabbit serum or TBR serum as previously described[3,7]. Portions of the immunoprecipitated proteins were subjected to discontinuous SDS-polyacrylamide gradient gel electrophoresis (5–15% acrylamide)[3], and the fixed, dried gels were autoradiographed. Tracks 1–4, normal rabbit serum; tracks 5–8, TBR serum. Tracks 1, 5, transformed clone 1T; tracks 2, 6, transformed clone 22T; tracks 3, 7, revertant subclone 866R; tracks 4, 8, revertant subclone 4R. ^{35}S-methionine-labelled T7 virion proteins were included as molecular weight markers; numbers in kilodaltons.

European field vole (*Microtus agrestis*) cells, since not only could we obtain revertants of these transformed cells that exhibited the normal cellular morphology, but also these particular cells contained levels of pp60^{src} similar to the transformed vole cells[9–12]. Moreover, as fully infectious transforming ASV can be recovered from the revertant vole subclones, loss of the transformed phenotype did not seem to result from a mutation affecting the *src* gene sequence[9–11]. Thus the reversion phenomenon in this vole cell system appeared to reflect either some post-translational alteration or lack thereof in pp60^{src}, or a defect in a host cell component(s) with which the *src* gene product must interact.

We report here that, although a slight alteration in the primary structure of pp60^{src} obtained from revertant vole cells was detected, this alteration does not seem to be responsible for loss of morphological transformation in the revertant vole cell types, as the slightly altered pp60^{src} molecule was also found in chick cells morphologically transformed by RSV rescued from these revertant vole cell subclones as well as subclones of spontaneous retransformants. Biochemical analysis of pp60^{src} from two revertant vole cell subclones indicates that, in at least one of the clones, morphological reversion is the result of an alteration in a cellular function rather than *src* itself. pp60^{src} isolated from these revertant vole cells exhibits protein kinase activity, suggesting that the presence of such an activity in cells is itself insufficient to induce morphological transformation. More importantly, as both of the revertant vole cells are tumorigenic it seems that one of the phenotypic parameters of cellular transformation can be expressed in the absence of another.

Phosphorylated pp60^{src} in transformed and revertant cells

Once the presence of the *src* gene product in the revertant vole cell clones[12] was established our initial studies were directed at determining whether any subtle differences could be detected in the structure of pp60^{src} obtained from transformed and revertant vole cells. Because the *src* gene product is a phosphoprotein, studies were carried out to determine if differences in phosphorylation existed between pp60^{src} obtained from transformed and revertant vole cells. ASV (Schmidt–Ruppin strain, subgroup D) transformed and morphologically reverted vole cells were radiolabelled with ^{32}P-orthophosphate and cell extracts were prepared by previously described procedures[3,7]. After immunoprecipitation with either non-immune rabbit serum or serum from rabbits bearing ASV-induced tumours (TBR serum)[3], the radiolabelled materials were subjected to electrophoresis in SDS-polyacrylamide gels. TBR serum precipitated a phosphorylated 60,000-MW protein from both transformed and both revertant vole cell lines (Fig. 1), whereas no such protein could be observed when non-immune rabbit serum was used for immunoprecipitation or when uninfected vole cell extracts were immunoprecipitated with this TBR serum. The intensity of the pp60^{src} bands in the autoradiogram suggests that the *src* gene product in both transformed and revertant cells was phosphorylated to a similar extent. Preliminary results have indicated that proteolytic peptides of phosphorylated pp60^{src} from transformed and revertant cell lines are similar. However, more detailed studies concerning the phosphorylation of the *src* protein in this system are now in progress.

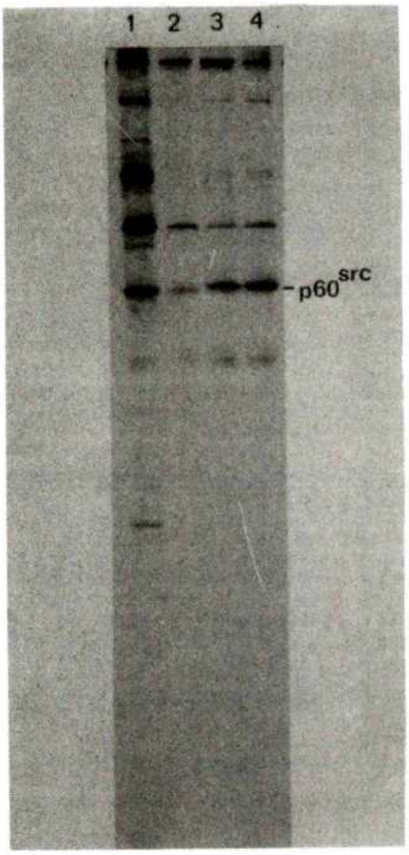

Fig. 2 Detection of a difference in electrophoretic mobility in SDS-containing polyacrylamide gels of pp60^{src} from transformed and revertant vole cells. ^{35}S-methionine labelled samples immunoprecipitated with TBR serum as described in Fig. 1 were electrophoresed in a discontinuous SDS-containing polyacrylamide slab gel consisting of a 4.2% acrylamide, 0.1% bisacrylamide stacking gel and a 10% polyacrylamide (38:1 acrylamide: bisacrylamide) separation gel, 14 cm long. Track 1, transformed clone 1T; track 2, transformed clone 22T; track 3, revertant subclone 866R; track 4, revertant subclone 4R.

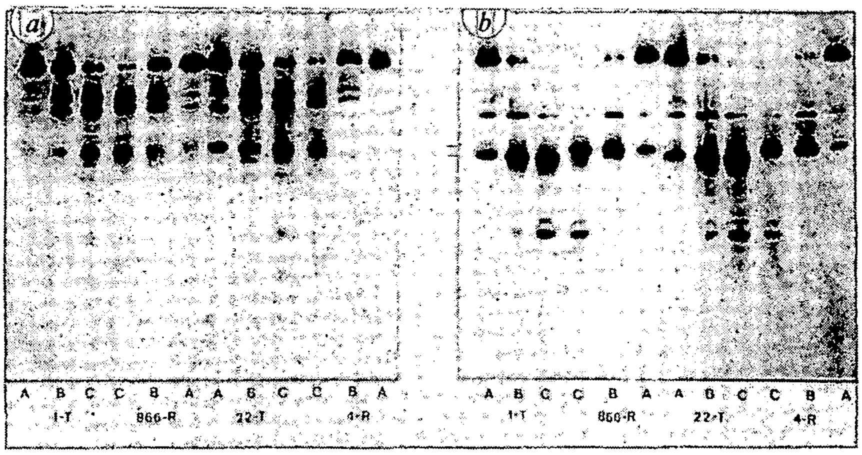

Fig. 3 Partial proteolysis mapping of pp60^{src} from transformed and revertant vole cells. ^{35}S-methionine labelled pp60^{src} proteins immunoprecipitated from the various vole cell lines were excised from preparative polyacrylamide gels and subjected to limited proteolysis during re-electrophoresis as described previously[13]. *a*, Digestion with chymotrypsin. Tracks A, 0.1 μg enzyme; tracks B, 0.6 μg enzyme; tracks C, 2.5 μg enzyme. *b*, Digestion with *Staphylococcus aureus* V8 protease. Tracks A, 0.001 μg enzyme; tracks B, 0.005 μg enzyme; tracks C, 0.05 μg enzyme. The lines in the margin of *b* indicate the V8 protease 26,000-MW peptide (the C-terminal 40% of the pp60^{src} protein molecule)[14] which shows an altered mobility between the revertant and transformed cell proteins.

Difference in electrophoretic mobility of pp60^{src} from transformed and revertant cells

^{35}S-methionine labelled proteins were also immunoprecipitated from extracts of both clones of transformed and revertant vole cells and electrophoresed on a slab gel longer than used in our initial studies in an effort to better resolve the pp60^{src} proteins (Fig. 2). The pp60^{src} proteins isolated from the two transformed cell lines co-migrated, as did the proteins from the two revertant subclones. However, the proteins from the revertant cell lines showed a slightly slower electrophoretic mobility than those from the transformed clones. As the pp60^{src} proteins from transformed vole and chicken cells co-migrate in these conditions (data not shown), these results suggest that the pp60^{src} protein present in the two revertant clones may represent an altered *src* gene product.

Proteolysis mapping of pp60^{src}

For a better assessment of the similarities and any possible differences in the pp60^{src} proteins from the transformed and revertant vole cells, one-dimensional peptide analyses were performed on ^{35}S-labelled pp60^{src} with both chymotrypsin (Fig. 3*a*) and *Staphylococcus aureus* V8 protease (Fig. 3*b*)[13]. The chymotrypic peptides generated by this partial proteolysis of the four proteins were all very similar if not identical (Fig. 3*a*). The V8 protease digestion patterns of pp60^{src} from the two transformed cell lines also appeared identical (Fig. 3*b*). However, both revertant cell pp60^{src} proteins exhibited V8 protease peptides that differed in electrophoretic mobility from the corresponding peptides of the two transformed vole cell lines (Fig. 3*b*, margin lines). The initial digestion products resulting from V8 protease digestion of pp60^{src} are two peptides of MW ~34,000 and 26,000 (ref. 14). The larger V8 protease fragment represents the amino-terminal 60% of the pp60^{src} molecule and the smaller fragment encompasses the carboxy-terminal 40% (ref. 14). Thus, it seems that the pp60^{src} C-terminal V8 protease peptide in both of the revertant cell lines was changed to a peptide of slightly slower electrophoretic mobility, confirming the slight alteration in pp60^{src} obtained from these revertant cells observed by polyacrylamide gel electrophoresis (Fig. 2).

In an attempt to determine if the altered V8 protease peptide of pp60^{src} from the two revertant subclones represented either a stable genetic change, or a variation in secondary protein modification or processing by the revertant cells, virus was rescued from the two revertant subclones and used to infect chicken cells. The ^{35}S-methionine-labelled pp60^{src} proteins were then isolated from these rescued virus-infected (and transformed) avian cells and subjected to partial proteolysis mapping using V8 protease as described above. When the protein obtained from the revertant subclone 4R rescued virus-infected chick cells (4R chick) was analysed, peptide fragments identical to those of pp60^{src} from the 4R revertant vole cells (4R vole) were obtained (Fig. 4*a*), suggesting that the alteration in the C-terminal V8 protease peptide of the *src* protein in this revertant subclone represented a stable change. In addition, we have been able to isolate clones of cells from cultures of our revertant cells grown to high cell density that appear to have regained the transformed phenotype. These re-transformed (RT) clones have also been used for *src* protein analysis. V8 protease peptide mapping of pp60^{src} from a re-transformed clone of the 4R revertant cells (4RT vole) again revealed no change from the pattern observed in the protein from the parent revertant cell line (Fig. 4*a*).

Similar peptide analyses were performed on the *src* protein isolated from chick cells transformed with revertant subclone 866R rescued virus (866R chick) and a clone of re-transformed

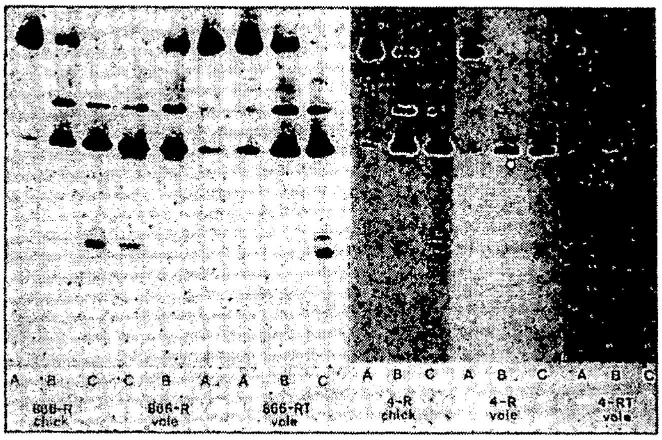

Fig. 4 Partial proteolysis mapping of pp60^{src} from rescued virus-infected chick cells and re-transformed vole cells. The rescue of ASV from the revertant vole cell subclones 4R and 866R by Sendai virus-mediated fusion with chick fibroblasts was performed by the procedure of Boettiger[19] as previously described[9]. The rescued virus (SR-ASV, subgroup D) obtained from the supernatant fluids of the fusion culture was used to infect chick cells. The infection resulted in virus production and the complete transformation of the chick cell culture. Re-transformed cell lines (4RT and 866RT) were obtained by picking cells that appeared morphologically transformed from 4R and 866R revertant subclones that were grown and maintained at high cell densities. The re-transformed cell lines maintain their transformed morphology on continuous subculturing. ^{35}S-methionine labelled pp60^{src} was immunoprecipitated from the rescued virus-infected chick cells (4R chick and 866R chick), the re-transformed vole cells (4RT and 866RT vole), and the original revertant subclones (4R vole and 866R vole) and subjected to V8 protease partial proteolysis as described in Fig. 3 legend. Tracks A, 0.001 μg enzyme; tracks B, 0.005 μg enzyme; tracks C, 0.05 μg enzyme.

vole cells from this revertant cell line (866RT vole) (Fig. 4*b*). As was the case with the 4R revertant cells the two major V8 protease peptides of pp60^{src} from these cell types were all identical. Although it first appeared that this revertant cell clone might be similar to the 4R clone, a closer inspection of the peptide maps of the 866R clone revealed that a slight, but reproducible, difference did exist between the two revertant vole cell subclones. This difference reflected the presence of an additional peptide band immediately below the major C-terminal V8 protease fragment in the parental 866R revertant vole cell line (Figs 3 and 4*b*). Moreover, this particular peptide was absent in V8 protease hydrolysates of pp60^{src} from either chick cells infected with RSV rescued from the 866R cells or spontaneous re-transformants of this revertant vole cell clone (Fig. 4*b*). Although it may be involved in the morphological reversion of this cell line, the significance of this extra peptide is unclear. The presence of the peptide only in the revertant vole cell pp60^{src} and not in the *src* proteins derived from the rescued virus-infected (and transformed) chick cells and the re-transformed vole cells suggests that this alternation is not genetically stable and may be specific for the pp60^{src} of this revertant line. Nevertheless further studies are needed to determine whether this peptide represents expression of a *src* gene from a second ASV present in this particular revertant cell line.

Table 1 Quantitation of pp60^{src} protein and pp60^{src}-associated protein kinase activity in transformed and revertant vole cells

Cell line	pp60^{src} Protein (μg per mg cell protein)	Specific activity of pp60^{src} protein kinase (fmol ^{32}P incorporated per μg pp60^{src})	Total pp60^{src} protein kinase activity (fmol ^{32}P incorporated per mg cell protein)
Transformed 1T	0.30	135	40.5
Transformed 22T	0.07	383	26.8
Revertant 866R	0.21	321	64.2
Revertant 4R	0.13	259	33.7

Cultures were labelled with 25 μCi ml^{-1} of ^{35}S-methionine for 2 h, and cell extracts were prepared as described previously[3,7]. Samples were taken for the determination of protein content, and portions were immunoprecipitated with TBR serum. The amount of pp60^{src} protein in each extract was determined as previously described[18]. The resulting kinase activities, determined by quantitation of the phosphorylated IgG bands from polyacrylamide gels, were normalised with respect to the amount of cell extract protein used for the immunoprecipitation.

pp60^{src}-associated protein kinase activity

As the pp60^{src} proteins from both revertant cell lines appeared structurally different from those obtained from the two transformed vole cell lines, we attempted to determine if they were functionally altered. It has been found[6-8] that pp60^{src} is associated with a protein kinase activity. Using what is now considered to be the conventional assay for pp60^{src} protein kinase activity, we have found that both revertant, as well as both transformed, vole cell lines show pp60^{src}-protein kinase activity (Table 1). No correlation can be made between the concentration of the *src* protein or the specific activity of pp60^{src}-protein kinase and the transformed or morphologically reverted state of the ASV-infected vole cells (Table 1).

Discussion

The slower electrophoretic mobility of the C-terminal V8 protease peptide of pp60^{src} from the revertant subclones represents a stable genetic change; however, it does not seem to impair the ability of the protein to induce morphological transformation. It is possible that the revertant subclones studied here were originally infected with a viral variant of SR-ASV or a different, contaminating strain of ASV, and that this is the reason for the differences in the pp60^{src} peptide maps. This seems unlikely as the immunoprecipitation with our TBR serum is strain specific for pp60^{src} of SR-ASV[16,17], and neutralisation data indicate that the rescued viruses obtained from the two revertant cell lines are the SR subgroup D strain of ASV. Peptide analyses on the *src* protein of other strains of ASV (Prague, Bratislava, Bryan) have shown that some variation in the V8 protease peptide maps does exist[17]. However, none of the viral pp60^{src} proteins studied so far have exhibited the peptide pattern (altered mobility of the C-terminal V8 protease peptide) of the proteins obtained from the two revertant vole cell lines studied here. It is of interest that a normal avian cell protein related to pp60^{src}, designated pp60^{sarc}, does have a C-terminal V8 protease peptide of the same electrophoretic mobility as those of the *src* proteins of the two revertant cell lines[18]. Additional subclones of revertants are now being isolated and peptide analyses of their pp60^{src} proteins being performed to determine if morphological reversion is always accompanied by the change in the C-terminal V8 protease peptide.

Although the pp60^{src} proteins in the transformed and revertant vole cells appear structurally different, they all exhibit protein kinase activity. It is possible that the *src* function involved in the changes in cellular morphology is not the pp60^{src}-associated protein kinase. It is also highly possible that pp60^{src} has other enzymatic activities. Alternatively the change in the *src* protein of the revertant cells may have altered *src* kinase specificity and/or cellular target recognition. Finally, the change in the pp60^{src} protein of the revertant cells may have nothing to do with the reversion process, but rather changes in the cells themselves have resulted in the ineffective action by the *src* protein in morphological transformation. For example, a cellular substrate of pp60^{src} may have been altered in such a way that it is no longer phosphorylated by the *src* kinase. This possibility appears highly plausible as the pp60^{src} protein from both revertant vole cell clones are able to cause morphological transformation in chicken cells and in retransformed vole cells. Thus, the transformed and revertant vole cells should provide an appropriate system to facilitate the identification of the target(s) of the ASV *src* gene product.

Is Z Cha another case of gravitational radiation?

H. Ritter

Max-Planck-Institut für Astrophysik, Föhringer Ring 6, D-8000 München 40, FRG

Z Cha is an eclipsing cataclysmic binary with an extremely short orbital period of only $P = 0.07449923$ d (ref. 1). Cataclysmic binaries are systems consisting of a white dwarf primary, of mass M_1, and of a secondary of low mass M_2, which fills its critical Roche volume[2]. The secondary feeds an accretion disk around the primary by transferring matter through the inner lagrangian point L_1. At the point where the streaming matter impacts the disk, a shock front is formed which is usually referred to as the hot spot. The geometry of the system, as seen from above the orbital plane, is shown in Fig. 1. The determination of the masses, the absolute dimensions and the mass exchange rate of Z Cha are reported here. Various possible mechanisms for the mass exchange are discussed which lead to the conclusion that it is probably due to the action of gravitational waves.

High-speed photometry observations[1] of Z Cha have clearly shown that two separate emitting regions undergo phase shifted total eclipses. These emitting regions are the hot spot and the centre of the accretion disk including the white dwarf primary. The half widths[4] of the white dwarf eclipse, Δt_{WD}, and of the hot spot eclipse, Δt_{HS}—as well as their mutual phase shift δt—have been determined from improved photometric observations[3]. In addition the durations of the partial phases of the corresponding eclipses, Δ_{WD} and Δ_{HS} have been estimated[5]. The resulting numerical values of Δt_{WD}, Δt_{HS}, δt, Δ_{WD} and Δ_{HS} are listed in Table 1*a*. Recent spectroscopic observations[6] have enabled the radial velocity K_1 and the projected orbital velocity of the accretion disk $v \cdot \sin i$ to be determined. These quantities are also listed in Table 1*a*.

The masses and the absolute dimensions of the system can be determined directly if the standard assumption[7] is made, namely that $v \cdot \sin i$ is the keplerian rotation velocity at the hot spot's distance, d, from the centre of the disk. Analysis of the double eclipse using a method described elsewhere[4] yields two equations for the mass ratio M_1/M_2 and the orbital inclination i in terms of R_2/A and R_2/A_S. Using geometrical relations shown in Fig. 1 and those of the keplerian orbit these equations can be solved[5]. The resulting main parameters of Z Cha are listed in Table 1*b*. The radii of the white dwarf primary, R_1, and of the hot spot, R_{HS}, have been computed from the durations of the partial phases of the corresponding eclipses[5].

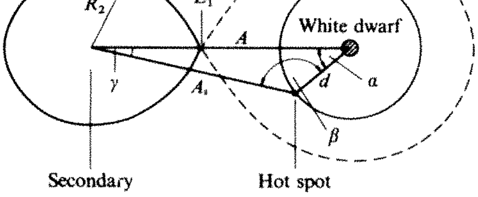

Fig. 1 Geometry of Z Cha as seen from above the orbital plane. Except for the radius of the hot spot the drawing is to scale.

Most remarkably, although the secondary was not assumed to be a main sequence star (an assumption usually made when discussing cataclysmic binaries[2,7]) it turns out that the secondary lies almost exactly on the theoretical mass–radius relation of low mass main sequence stars[8]. Even more surprisingly the primary fits the theoretical mass–radius relation of white dwarfs[9,10]. Both these findings are not self-evident and must be considered as a confirmation of the reliability of the parameters given in Table 1. An additional consistency check is provided by comparing the value of α (see Fig. 1) given in Table 1*b* with the value $\alpha \simeq 34°$ derived from observations[1]. The agreement is quite good. (Note that there apparently is an error in ref. 1 and that in fact $\alpha = 34°$ and not $\alpha + \gamma = 34°$; details will be given elsewhere[5].) Moreover, if Δt_{HS} is replaced by α (34°) as an input parameter in the above analysis the values of all the resulting parameters are almost identical to those given in Table 1*b*.

It is now possible to estimate the rate of mass exchange, $\dot{M}$, by determining the luminosities of the hot spot and/or of the accretion disk. The rather lengthy procedure necessary to transform relative amplitudes of the observed light curves[1] into absolute luminosities is described elsewhere[5]. Basically the procedure involves four steps. First, the relative amplitudes of the different emitting regions, that is, of the secondary, the hot

spot and the accretion disk including the white drawf primary, have been determined from observations of Z Cha at minimum light[1]. Second, the measured amplitudes of the different emitting regions in 'white light' (ref. 1) have been converted to relative bolometric amplitudes, taking into account the different effective temperatures of the different emitting regions. Third, an absolute luminosity for one of the emitting regions must be determined. This has been done by assuming that the secondary is a normal main sequence star[8] as indicated by its position in the mass–radius diagram. Finally the absolute luminosities of the hot spot and of the accretion disk have been computed and directly converted into accretion rates[5,11]. The accretion rates determined in this way, $\dot{M}_{\mathrm{HS}}$ from the hot spot luminosity and $\dot{M}_{\mathrm{D}}$ from the disk luminosity, are listed in Table 2. The errors given are purely formal, the rates themselves are probably known only within a factor of 2.

Knowing the approximate accretion rate, what mechanism can give rise to a corresponding mass exchange rate? The most obvious mechanism, namely nuclear evolution of the secondary, can be ruled out because the secondary has a mass of only $\sim 0.16 M_{\odot}$, and is almost certainly fully convective[8] and thus remains chemically homogeneous throughout its evolution. This has the effect of decreasing the star's radius with time. Thus no mass exchange can be expected in these circumstances. However, even if the secondary were not fully convective it would increase its radius a nuclear time scale $\tau_{\mathrm{nuclear}} \approx 10^{12}$ yr giving rise to a mass exchange rate of only $\dot{M} \approx 2 \times 10^{-13} M_{\odot}\,\mathrm{yr}^{-1}$. This is two orders of magnitude less than that estimated from observations.

The second likely mechanism, namely mass loss by the secondary on a thermal time scale, due to thermal readjustment, can also be ruled out. This is because the system, which has a mass ratio $M_1/M_2 \approx 2.2$, is secularly stable against mass exchange unless the mass–radius exponent of the secondary $\alpha_2 = d \log R_2 / d \log M_2$ is less than -0.7. However, the corresponding value of α_2 for a $0.16 M_{\odot}$ main sequence star is $\alpha_2 \approx +0.7$. In fact, even in the worst case of deviation from thermal equilibrium, that is when the fully convective star expands adiabatically, α_2 is only $-1/3$ and the system would still be secularly stable against mass exchange.

Thus the most obvious, classical mechanisms of mass exchange are insufficient to explain the observations of Z Cha. On the other hand, it has been suggested that cataclysmic variables, such as Z Cha, should exchange matter as a consequence of angular momentum loss due to gravitational radiation[12]. (Note that this mechanism has the *a priori* advantage of always forcing the binary to some mass exchange independent of the mass–radius exponent of the mass-losing star.) According to Einstein's quadrupole formula[13], gravitational waves should give rise to a mass exchange rate[12]

$$\dot{M}_{\mathrm{GR}} = \frac{32 G^3}{5 C^5} (M_1 + M_2) M_1 M_2^2 A^{-4} \times \left[\frac{M_1 - M_2}{M_1} + \frac{1}{2} \left(\alpha_2 + \frac{M_1 + M_2}{M_1} \frac{d \log f_2}{d \log (M_1/M_2)} \right) \right]^{-1} \qquad (1)$$

where f_2 is the Roche radius of the secondary in units of the system's separation A. The numerical value of $\dot{M}_{\mathrm{GR}}$ corresponding to the parameters listed in Table 1*b* is given in Table 2 and can thus be compared directly with the estimates $\dot{M}_{\mathrm{D}}$ and $\dot{M}_{\mathrm{HS}}$. Gravitational radiation apparently induces just that amount of mass exchange—within the uncertainties—estimated from observations. Moreover, unless one were prepared to accept rather exotic mechanisms for the mass exchange the only mechanism capable of explaining mass exchange at the observed level in a natural way is loss of angular momentum due to gravitational radiation. It can therefore be concluded that Z Cha is, in addition to the binary pulsar[14], another example of the action of gravitational radiation.

Dissipation, merging and the rotation of galaxies

S. Michael Fall

Institute of Astronomy, University of Cambridge, Madingley Road, Cambridge and Center for Astrophysics, Cambridge, Massachusetts

The distinction between elliptical and disk galaxies is often explained by invoking different rates of dissipation and star formation in the proto-galactic gas clouds from which they are presumed to have formed[1–3]. Another possibility is raised by the suggestion that many ellipticals are the remnants of galaxies that merged while suffering the tidal distortion and violent relaxation of a slow encounter[4,5]. Various *N*-body simulations indicate that merging can account for many of the observed properties of bright elliptical galaxies[6–9], although some reservations have been expressed about the possibility of accounting for their low rotation velocities[10]. My aim here is to consider a specific model for the formation of disk galaxies by dissipation and the formation of bright ellipticals by merging and to suggest that it can account for their rotation properties in a natural way.

The rotation of a self-gravitating body is conveniently expressed in terms of the dimensionless spin parameter $\lambda \equiv J |E|^{1/2} G^{-1} M^{-5/2}$ where J, E and M are respectively the total angular momentum, energy and mass of the body and G is the gravitational constant. In the hierarchical clustering picture, all structures are endowed with some rotation before collapse as a consequence of their mutual tidal torques. The characteristic spin of this mechanism is $\lambda_{\mathrm{T}} \simeq 0.07$ and any significant differences from this value must be the result of non-gravitational effects[11,12]. An elliptical galaxy has $\lambda \simeq 0.3 (v_r / \sigma_r)$ where v is the peak rotation velocity along the major axis and σ_r is the line-of-sight velocity dispersion near the centre of the galaxy[6]. The measurements of these velocities for 25 bright ellipticals[13–17] give the average spin value $\lambda_{\mathrm{E}} \simeq 0.08$ and the distribution shown in Fig. 2 (neglecting small corrections for the

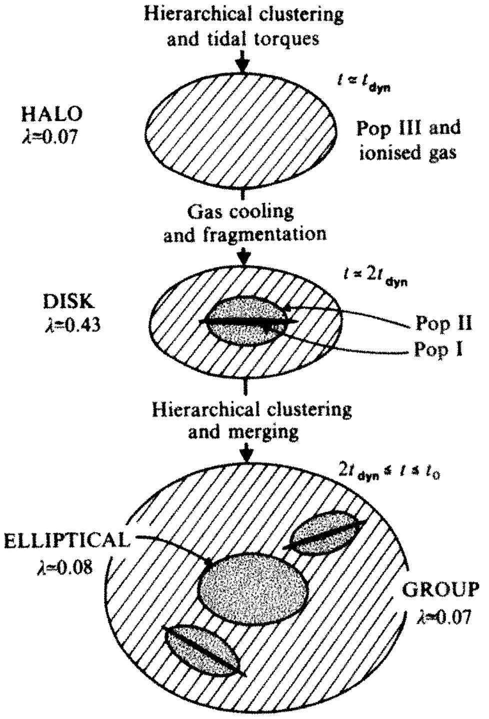

Fig. 1 Evolutionary sequence discussed in the text. Pre-galactic haloes are formed by the hierarchical clustering of dark stars and gas; disk galaxies result from dissipation and fragmentation within the haloes; elliptical galaxies are produced by merging in small groups.

orientations of the galaxies and uncertainties in the observations). Disk galaxies appear to be supported by rotation alone and, to the extent that this is true, have $\lambda_{\rm D} \simeq 0.43$. (This follows from equations 9, 11 and 14 of ref. 18, equation 6 on page 386 of ref. 19 and the virial theorem; it is exact for a cold exponential disk without a bulge component.)

The proposed evolutionary sequence, illustrated in Fig. 1, is based on the picture of galaxy formation and clustering outlined by White and Rees[20]. In their view, pre-galactic haloes formed by gravitational clustering and consisted of low-mass or burnt-out stars (pop III) along with some residual gas. If the gas was originally ionised (for example by shocks), the condition that it could cool and collapse within the dark haloes sets their characteristic mass and (half-mass) radius at $M_{\rm H} \simeq 5\times 10^{12} M_\odot$ and $R_{\rm H} \simeq 150$ kpc (to rough accuracy[20]). The most likely outcome of this dissipative process would seem to be a population of disk galaxies[21] (spirals if some gas was retained, lenticulars if it was depleted or removed). Their characteristic masses and radii must have been set by the poorly understood details of the collapse process and will therefore be parametrised in terms of the halo values: $M_{\rm D} \simeq xM_{\rm H}$ and $R_{\rm D} \simeq yR_{\rm H}$. On observational grounds[18,22–24], the values $x \simeq y \simeq 0.1$ are indicated and they satisfy the condition that the gas was able to reach a self-gravitating state before fragmenting into stars. The tidal spin of the haloes and the condition that angular momentum was conserved during the collapse of the gas now lead to the characteristic spin $\lambda_{\rm D} \simeq (xy)^{-1/2}\lambda_{\rm T}$ for disk galaxies (neglecting geometrical factors of order unity). This estimate is based on the suggestion that any mechanisms for the transport of angular momentum (such as turbulent viscosity) would not have been efficient during collapse[25], and it agrees with the empirical spin value for $xy \simeq 0.03$.

Gravitational clustering on scales larger than the individual haloes would not have been influenced by their internal dissipation and would have given rise to the observed hierarchy of groups and clusters[26,27]. The characteristic masses and radii of the groups are related to the number of member galaxies m by the expressions $M_{\rm G} \simeq mM_{\rm H}$, $R_{\rm G} \simeq m^{\alpha+1/3}R_{\rm H}$ where $\alpha \simeq 0.3$–0.5 is the index of the 'initial' perturbation spectrum $\delta\rho/\rho \propto M^{-\alpha}$. The groups of the first generation to reach equilibrium would have had about $m \simeq 2$–8 members and tidal stripping is expected to have detached most of the haloes from their galaxies in a fraction $0.08R_{\rm G}/R_{\rm H} \simeq 0.08m^{\alpha+1/3}$ of the first crossing time (equation A4 of ref. 20). This is expected to have left each group with a fairly smooth background of stripped halo material and to have left most of the luminous parts of the galaxies relatively undisturbed (so long as they are tightly bound). In this environment, the merging time scale for the galaxies themselves is about $0.03x^{-1}(M_{\rm G}/M_{\rm D}) \simeq 0.03mx^{-2}$ group crossing time scales (equation A7 of ref. 20) so about one merger per group is expected before its incorporation into the next level of the hierarchy. After that, the conditions for merging are less propitious, especially in large clusters, because merging cannot occur if the encounter velocities of the interacting galaxies are more than a few times their internal velocity disperions[6,7] ($\sim$250 km s^{-1}). This condition also implies that the ellipticals produced from n disk galaxies have characteristic masses and radii with the approximate values $M_{\rm E} \simeq nM_{\rm D}$ and $R_{\rm E} \simeq nR_{\rm D}$.

The spins of elliptical remnants can include contributions from both the orbital and the internal angular momenta of the disk galaxies that produced them. To the extent that the merging process was hierarchical, the internal contribution is negligible because the galaxies most likely to merge were those that formed near each other and therefore provided the mutual torques responsible for their equal and opposite tidal spins. Some of the merging in large groups may, however, have involved galaxies that did not form near enough to guarantee this cancellation. If they had no correlation, the typical contribution was $n^{1/2}J_{\rm D}$ to the angular momentum of a remnant and therefore $n^{-3/2}\lambda_{\rm D}$ to its spin. Thus, even in this extreme case, the internal contribution becomes negligible after about two merger

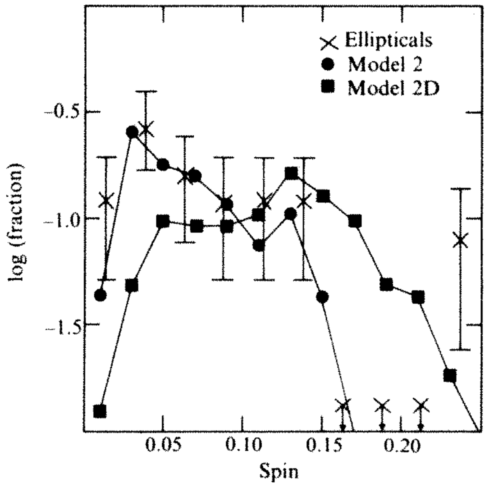

Fig. 2 Spin distributions. The normalised histogram for elliptical galaxies is from the data of refs 13–17 (listed also in Table 2 of ref. 9). The other histograms are for merger remnants at the end of two 1,000-body simulations that differ only in the initial spin values of their particles: $\lambda = 0.08$ for model 2 (one of the 'standard' simulations of ref. 9) and $\lambda = 0.40$ for model 2D (a new simulation with the same particle sizes, masses and orbits). The initial spin orientations are random and the final spin distributions are similar because of the statistical $n^{-3/2}$ dependence of the contribution from internal spins. Orienting the initial spins to cancel in pairs (by earlier tidal torques) would result in even more similar final distributions. The spin distributions are not sensitive to the sizes of the particles but they do depend somewhat on the initial position and velocity distributions (Poisson positions and Hubble velocities here). These simulations do not include a component of stripped halo material; however, the spins of merger remnants are not expected to depend sensitively on the presence of this component so long as it also participates in the hierarchical development of clustering.

events ($n \simeq 3$). The orbital contribution to the spins of elliptical remnants must have derived from tidal torques in the clustering hierarchy, with a maximum value set by the condition that interacting galaxies should have overlapped enough to have merged within a few orbital periods. (Otherwise, the orbits could have been disrupted and merging prevented.) The simulations of merging pairs of galaxies[6,7] indicate $\lambda_{\max} \simeq 0.2$ (for parabolic encounters with zero net internal spin) and the cosmological simulations[8,9] indicate that the average spin value of merger remnants is about $\frac{1}{2}\lambda_{\max} \simeq 0.1$. This is because the distribution of impact parameters is fairly flat and most merging is from marginally bound orbits. Figure 2 shows the results of two simulations by Dr S. J. Aarseth and myself; the agreement with the spin distribution of real ellipticals is reasonable in both cases.

In many respects, the specific model outlined here is undoubtedly over-simplified and leaves some important questions unanswered: How did the dwarf ellipticals form? Why are ellipticals virtually gas-free? What determines the colours of elliptical remnants? The model suggests that different dissipation and star formation rates need not be invoked at the formation epoch of bright galaxies to explain their later morphological differences. The real situation may, however, have involved a variety of galaxy formation processes with merging only responsible for the making of some ellipticals. Perhaps the main conclusion to be drawn from the line of reasoning presented here is that the low rotation velocities of bright elliptical galaxies are no embarrassment to the idea that they were produced by the merging of rapidly rotating disk galaxies.

I acknowledge helpful and interesting conversations with Sverre Aarseth, George Efstathiou, Martin Rees and Simon White.

The vertical structure and thickness of Saturn's rings

Jeffrey N. Cuzzi*, Joseph A. Burns†, Richard H. Durisen‡ & Patrick M. Hamill§

Observations of Saturn's rings over the last few years have contributed greatly to unravelling questions as to their nature and origin. However, some fundamental issues concerning the vertical structure and thickness of the rings have remained in dispute. In this note we present a synthesis of our results which reconciles most of the conflicting data. We first discuss the vertical structure and show how the many-particle-thick model appears to be feasible, but permits a local ring thickness of only a few tens of metres, much less than the thickness suggested by observations at ring-plane passage. We then describe how solar and satellite perturbations, which are coherent and not dispersive, do not significantly affect the true local vertical thickness of the rings, but do affect the tilt of the mean ring plane in a way that could be relevant to an understanding of the ring-passage observations.

One outstanding problem is the finding that the physical thickness of the saturnian rings is far too small to be directly observed. From measurements of the minimum brightness of the edge-on rings during ring-plane passage in 1966, ring thicknesses of 2.8 ± 1.5 km (ref. 1) and 1.4 ± 0.5 km (ref. 2) have been inferred. Reanalysis of these data[3], however, gives a thickness of 0.8 (+2.3, −0.8) km, implying that only an upper limit on the thickness of ~3 km may be confidently claimed.

A further question concerns the local vertical structure of the rings—are they many particles thick or are they essentially a monolayer? A ring that is many particles thick is the classical solution to the observed opposition effect[4]. Such a thickened ring implies random velocities with respect to the average local motion, and yet such velocities are continually damped by inelastic collisions between particles[5]. Such collisions occur about once per orbit for an optical depth of the order of unity. As a result, an originally 'thick' ring system flattens—in a time that is extremely short compared to 4.5×10^9 yr—to a layer that is at most a few particles thick unless the random motions are sustained by some ongoing source of energy. Obviously, in an essentially flat system, the ring thickness is of the order of the particle size. Thus, the above dynamical arguments and ring thickness 'observations' imply a monolayer with thickness (particle size) ~1 km; such a thickness is difficult to reconcile with either the opposition effect or with recent microwave observations[6,7].

Mechanisms considered as possible sources of energy for continual thickening of the rings include collisions among the particles[4,8–10] and perturbations of the system by the saturnian satellites and the Sun[4,10,11]. In recent studies[12,13] we have discussed these and less significant mechanisms, such as meteoroid bombardment and radiation pressure, in detail.

Although, as argued above, collisions quickly flatten a ring system, the flattening proceeds, at most, only to the point where the system is a few particles thick. This is easily understood: imagine a ring system, nearly a monolayer, of identical particles of radius R in an orbit with semimajor axis a about a planet. Because of their keplerian motion, neighbouring particles will have a relative tangential velocity $\sim \omega R$, where ω = local orbital angular velocity. Particles collide because of this shear motion and their finite radii and soon develop an out-of-plane velocity component comparable to the shear velocity difference ωR over a particle diameter. By conservation of angular momentum in such collisions, the rings spread radially, in the absence of other restrictions, until the particles no longer collide. Such an evolution—rapid collisional flattening to a thickness of a few particle radii, followed by a very gradual spreading—was introduced by

0028–0836/79/380202—03$01.00

Jeffreys[5], treated numerically by Brahic[9], and theoretically by Cook and Franklin[7] and Goldreich and Tremaine [10] with similar results. We also have investigated thickening mechanisms based on this 'Kepler shear' but applied to a ring system composed of particles of size distribution n_0R^{-3}, which is that expected for an ensemble of particles which, perhaps only very early in their history, but possibly also at present, undergo comminution and mutual fragmentation. A size distribution of this general type seems to be required to explain the wavelength independence of the radar reflectivity of the rings[6,7]. We have shown[12] that the ring system attains a steady state in which gravitational scattering by the large particles imparts random velocity components V_R to the small particles while inelastic particle collisions decrease these random velocities. This leads to a gaussian distribution $\exp(-z^2/z_0^2)$ of particle density with vertical displacement $z \sim aV_R/\omega a$.

Our results are not sensitive to the form of the size distribution. Suppose $n(R) = n_0R^{-p}$ with minimum and maximum particle radii $R_{\min}$ and $R_{\max}$. The energy balance equation for the random particle motions is of the general form[12]

$$f_1 = \frac{\int M^2 n(M)\,\mathrm{d}M}{\langle V_R \rangle^3}$$

where the constant f_1 includes the effects of inelastic collisions and Kepler shear, and depends only on ω, normal optical depth τ_0, and coefficient of restitution e. We may obtain the particle mass distribution $n(M)$ from $n(R)$, and we obtain n_0 from τ_0. Then,

$$n(M) = f_2 n_0 M^{-(p+2)/3}$$

where

$$n_0 = \frac{f_3(2-p)}{z_0(R_{\max}^{(3-p)} - R_{\min}^{(3-p)})}$$

and f_2, f_3 are constants.

Integrating over the size distribution, and using $z_0 = \sqrt{2}\langle V_R \rangle/\omega$, we obtain

$$z_0 = KR_{\max},\ p \leqslant 3$$

$$z_0 = K\left(\frac{R_{\max}}{R_{\min}}\right)^{(3-p)/4} R_{\max},\ 7 \geqslant p > 3$$

$$z_0 = KR_{\min},\ p > 7$$

where K varies only slowly with p, τ_0 and e. The result is independent of the exponent p of the size distribution for $p \leqslant 3$. If $(R_{\max}/R_{\min}) \leqslant 10^2$ or 10^3 (ref. 6), z_0 is still comparable to $R_{\max}$ for $p \leqslant 4.5$. Evaluating the constant K for $p = 3$ (ref. 12), we find that $z_0 \sim 5\ R_{\max}$.

Thus, although the full ring thickness is only about 10 times the radius of the largest particles, the ring is many small particles thick. Because the small particles dominate the surface area for an R^{-3} distribution, this can account for the optical observations[4,14] and microwave scattering behaviour[6,7]. An estimate of the maximum size of the ring particles following the R^{-3} size distribution can be obtained by showing that the gravitational energy given up in spreading the ring permits a ring thickness of only tens of metres to be sustained over the age of the Solar System. This implies that the maximum size particle in the power-law distribution is only a few metres in radius, similar to other estimates for uniform particle size cases[9,10]. This true thickness is, however, much smaller than has been inferred[1,2] from the ring-passage observations.

Dynamical perturbations of ring particles by the Sun and by Saturn's large satellites may be relevant to this discrepancy. Under the disturbing action of a single satellite along with the planetary oblateness, the pole of a particle's mean orbit plane can be found to precess at a nearly uniform rate and at a nearly constant inclination relative to a mean pole, that of the Laplace plane[13]; for a ring particle, because it moves near the very oblate Saturn, the Laplace plane is almost, but not quite, coincident with the planet's equatorial plane. Following the usual celestial mechanics terminology, the displacement normal to the ring plane is decomposed into terms of different periodicities: short period ($T \sim$ particle orbit period), long period ($T \sim$ orbital precession period, orbital period of perturber) and secular ($T \sim$ infinity). The short period effects due to satellite and solar perturbations have an amplitude $\sim (m_j/m_{♄})(a/a_j)^3 \sin I_j$ (ref. 14) where m_j, a_j, and I_j refer to mass, semimajor axis, and inclination of the jth perturber. These amplitudes are of the order of 1 m and are coherent. Long-period and secular perturbations due to both the satellites and the oblateness of Saturn have been considered numerically[4] and qualitatively[16] by Bobrov. The principal effect of the oblateness is to slew or precess the particle orbit planes. However, Bobrov's[16] amplitude of 300 m was taken from a numerical integration by Franklin[11], which did not include the planetary oblateness (F. A. Franklin, personal communication). Using a perturbation technique, we have obtained a closed form solution for the long-period and secular portion of the particle orbits' inclinations (measured relative to the Laplace plane) as perturbed by a satellite (or the Sun), including planetary oblateness and planetary precession[13]. Ignoring the latter effect, but including collisional damping, this forced inclination has constant amplitude $\omega_j \sin I_j(\omega_f + 2n_j)^{-1}$, and the forced precession of the orbit node is at the rate of $2n_j$, where n_j is the mean motion of the jth perturber, $\omega_j = Gm_j\alpha_j^2 B_1^{3/2}(\alpha_j)/(4na^3)$ is the precession rate of the particle's orbit plane due to the jth satellite with G the gravitational constant, $\alpha_j = \mathrm{a}/\mathrm{a}_j$, $B_1^{3/2}(\alpha_j)$ is a Laplace coefficient[13], and n is the particle's mean motion; $\omega_f = (3/2)J_2 n(r_0/a)^2$ is the precession rate of the particle's orbit plane due to the planetary oblateness represented by the gravitational coefficient J_2 as normalised to the saturnian radius r_0. It is the inclusion of the effects of oblateness, manifested in ω_f, that effectively reduces the amplitude of the satellite perturbation compared with previous results[4,11,16]. Typical amplitudes are less than a few metres due to the satellites, with Titan, Tethys, and Mimas being the only important ones, and $\sim$10 m for the response to the solar perturbation which has the same character; these amplitudes increase by about an order of magnitude from the inner to the outer edge of the ring. A similar and still coherent effect is produced by the precession of Saturn's equatorial plane under solar torques, whereby particles in the mean ring plane experience noninertial effects causing particle orbit inclinations to oscillate while following the precession cycle of Saturn.

The subsequent evolution of such 'coherent' perturbations, in particular whether they may be coupled into random motions of the ring particles, has long been debated. The nature of the mathematical solution given by Burns *et al.*[13] makes it fairly clear that there is no means by which this can occur. In contradiction to a previous suggestion[16], differential precession of orbits of particles having similar inclination and slightly different semimajor axes, is not a property of the forced solution which dominates in the presence of damping (energy loss in collisions), Such 'winding up' does occur for a particular set of initial orbits randomly distributed about the mean ring plane (see equation (71) of ref. 13). 'Initial' noncircular components (random velocities) are, however, damped out on the flattening time scale, and the solution relaxes to the fully forced case which is coherent and time-independent (see for example equations (67) and (68) of ref. 13).

The above mechanisms produce displacements from the mean ring plane that are much less than the nominal 'observed' ring thickness. However, the Laplace plane mentioned above, about which the several metre coherent displacements occur, is itself significantly inclined to Saturn's equator by an amount that depends on the relative strength of the gravitational influence of Saturn and the various perturbing satellites, and hence on the semimajor axis a of the particle orbit. Thus, the inclination of the mean ring plane varies with radial distance throughout the ring system, giving vertical displacements at the outer edges of the rings of about $\pm 10^2$ m each for perturbations due to Mimas, the Sun, and Titan, and smaller values for the other satellites. The nature of the result is a ring that is 'flipped' up and down at its opposite edges by possibly a total difference of several hundred metres, depending on the orbital parameters of the various perturbers. In addition, light scattered by the exterior, diaphanous E ring could also be misinterpreted as a 'thickness' of about 100 m or more[13]. Although the total effect is still much less than the 3 km 'upper limit' suggested by Lumme and Irvine[3], it is not so far from their formal 'best result' of 800 m.

In conclusion, the 'vertical' structure and thickness' of the rings encompass several distinct phenomena, produced by different causes and manifested in different observations. The quality that best describes the local microstructure of the rings is probably a true thickness of some tens of metres, caused by local, gravitationally induced, random particle motions; such a vertical structure is consistent with the opposition effect[4,14] and with microwave observations[6,7]. Satellite and solar perturbations produce two significantly different effects. First, coherent metre-scale vertical displacements, similar for all particles with similar orbital elements, are superposed on the local mean ring plane. There are both long-period and short-period displacements. The long-period displacements are characterised by particle orbits with a constant forced inclination and nodes that advance at twice the mean motion of the satellite perturber. The short-period displacements are tied to the longitude of the perturber. Second, the vertical displacement from the saturnian equatorial plane characterising the mean ring plane varies nonlinearly with radial distance and may produce an apparent edge-on thickness of several hundred metres, which would make it impossible for the true 'thickness' or local vertical scale height of the rings ever to be determined by ring-passage observations.

Our result—namely, that considerations of energy balance, combined with an R^{-3} power law with maximum radius $R_{\max}$, allow an approximate $R_{\max}$ of only several metres—has interesting implications for the origin of the rings. Particles that condensed directly from a protoplanetary nebula might be expected to be of this size, whereas residual particles resulting from Roche breakup of a large object would be expected to be significantly larger[16,17].

We acknowledge helpful conversations with A. Brahic, F. Franklin, P. Goldreich, R. Greenberg, R. Miller, and J. Pollack. Discussions with W. Ward concerning interpretation of our analytical results were particularly helpful. This work was initiated when the authors were at Ames Research Center, NASA; J.A.B. on an Intergovernmental Personnel Exchange Act, and J.N.C. and R.H.D. as NAS–NRC Resident Research Associates; P.H. was supported partly under NASA grant NSG-2227.

Kinetics of electron attachment to oxygen and water in flames

J. M. Goodings* & A. N. Hayhurst

Department of Chemical Engineering and Fuel Technology, University of Sheffield, Mappin Street, Sheffield, UK

Negative ions are found in flames[1] and are presumed to arise from electrons attaching to some unidentified flame species, possibly molecular oxygen[2,3]. Free electrons and positive ions are produced in a flame either by chemi-ionisation[4] in $CH+O \rightarrow CHO^{+}+e^{-}$ or by collisional ionisation[5] of a metal, such as potassium, in $K+M \rightarrow K^{+}+e^{-}+M$, where M represents a third body. An atmospheric pressure flame is an interesting medium in which to measure the rate of appearance of negative ions; normally no more than one particle in 10^6 is electrically charged, there are usually no electric or magnetic fields and the attaching electrons are 'thermalised', that is, their energies are governed by the flame temperature. In addition, electron attachment is at much higher temperatures and pressures than normal[6,7] and in a system free from wall effects. We present here a study of the kinetics of electron attachment to oxygen and water in flames. The rate coefficients suggest a surprisingly large negative temperature coefficient.

Most of this work was done with an oxygen-rich atmospheric-pressure flame of unburnt composition: $H_2/O_2/N_2 = 1.5{:}1.0{:}4.67$ and temperature 1,810 K. The burner[8] gave a cylindrical flame (diameter 12.2 mm) with an almost flat reaction zone, followed by a burnt gas region in which there was laminar and plug flow, with conditions on the axis being unaffected by the surrounding atmosphere for around the first 25 mm. The mole fractions of the major constituents of the burnt gases were: $O_2 = 0.0379$; $H_2O = 0.233$; $N_2 = 0.726$. In addition, radicals were present with mole fractions for equilibrium in the burnt gases of: $H = 2.97 \times 10^{-6}$; $OH = 6.80 \times 10^{-4}$; $O = 2.42 \times 10^{-5}$; $HO_2 = 2.45 \times 10^{-7}$. Concentrations of H atoms were measured on a slightly different burner by an adaptation[9] of the Li/Na comparison method[10]. The results were expressed as a disequilibrium parameter γ_H ($=[H]/[H]_e$), that is, the extent by which hydrogen atoms exceed their equilibrium concentration $[H]_e$ for the almost constant temperature of the burnt gases. It can be shown that $\gamma_H^{1/3} = \gamma_{OH} = \gamma_O^{1/2}$. Values of γ_{OH} in this flame were ~8 close to the reaction zone and ~1.4 at 20 mm downstream, after a time elapse of 3 ms. Because the axial velocity (7.0 m s^{-1}) in the burnt gases is well defined, observations of ion concentrations at different distances enable kinetic measurements to be made.

Free electrons were produced by atomising an aqueous solution of KOH into the burner supplies. Ion concentrations were measured, as previously described[11,12], by continuous sampling from points along the burnt gases into a quadrupole mass spectrometer. The major ions were K^+, $K^+.H_2O$, OH^-, $OH^-.H_2O$ and O_2^-. Their abundances along the flame are given in Fig. 1, where the concentrations of hydrates have been included in those of the parent ions, because hydrates are largely formed during sampling[13]. Charge neutrality enables the electron concentration to be derived from $[e^-] = [K^+] - [Y^-]$, with $[Y^-] = [OH^-] + [O_2^-]$, that is, the total concentration of negative ions. Figure 1 shows that $[e^-]$ and $[K^+]$ rise much more rapidly than $[OH^-]$. This is consistent with K atoms undergoing collisional ionisation to give K^+ and free electrons, followed by electron attachment yielding O_2^- and OH^-. The ratio $[OH^-]/[O_2^-]$ increases with distance to a steady level above that calculated for equilibrium. That the ratio initially rises suggests

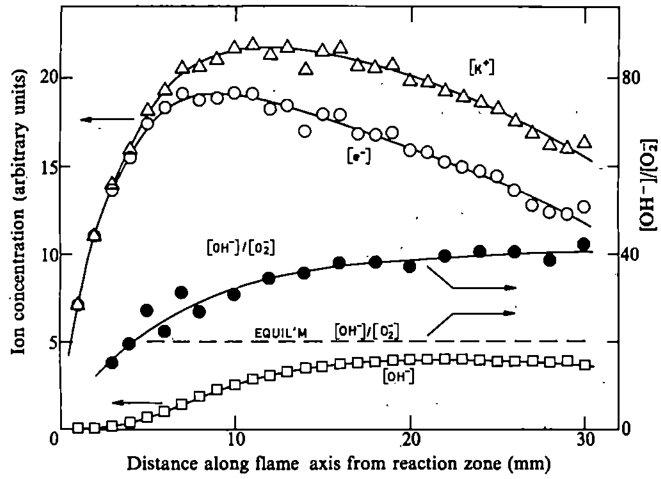

Fig. 1 Ion concentrations along the axis of the flame described in the text with 3×10^{-3} M KOH being sprayed in the atomiser. Also shown is the observed $[OH^-]/[O_2^-]$, together with its equilibrium value of 20.1 (dashed line).

that OH^- is produced from O_2^-. The near constancy of the ratio indicates that some rapid reaction couples the concentrations of OH^- and O_2^-, coming close to a local balance or equilibrium after a few millimetres. In contrast, the ratios of either $[OH^-]$ or $[O_2^-]$ to $[e^-]$ are not constant, being smaller than their equilibrium values, which in fact are approached well downstream. All this indicates that electron attachment giving O_2^- and OH^- is slow enough here to be a kinetic, rather than a steady-state, situation.

The possible formation and loss reactions for OH^- and O_2^- are:

$$
\begin{array}{rll}
e^- + O_2 + M \rightleftarrows O_2^- + M & (1) & k_1 = 1\times10^{-30} \\
O_2^- + OH \rightleftarrows OH^- + O_2 & (2) & \\
e^- + OH + M \rightleftarrows OH^- + M & (3) & k_3 = 3\times10^{-31} \\
e^- + H_2O \rightleftarrows OH^- + H & (4) & k_4 = 4\times10^{-17} \\
 & & k_{-4} = 1\times10^{-11} \\
e^- + HO_2 \rightleftarrows OH^- + O & (5) & k_{-5}(298\text{ K}) = 2\times10^{-10} \\
e^- + H_2O_2 \rightleftarrows OH^- + OH & (6) &
\end{array}
$$

where k_x and k_{-x} are the rate constants of the forward and reverse steps of reaction (x), whose equilibrium constant $K_x = k_x/k_{-x}$. The quoted values are those recommended by Jensen and Jones[14] for 1,810 K in the ml molecule^{-1} s^{-1} system of units. Reaction (3) can be discounted in our flame, as not being competitive with (1); similarly, step (−3) is much slower than (−1) because the electron affinity of OH exceeds that of O_2. It might be noted that reaction (3) is the sum of (1) and (2), so that $K_3 = K_1K_2$. The value given for k_{-5} refers to room temperature[15]; k_{-6} has not been measured, although steric effects might be expected to make it smaller than k_{-4} and k_{-5}, for which the neutral reagent is atomic. Reaction (2) is the most likely interconversion process for OH^- and O_2^-, in which case Fig. 1 indicates it is close to being balanced a few mm from the reaction zone. Also, the initial rise in $[OH^-]/[O_2^-]$ is consistent with O_2^- being the first negative ion formed; that this ratio exceeds its equilibrium value is because $\gamma_{OH} > 1$ and, more importantly, reaction (2) is fast enough to proceed in the exothermic direction during sampling[8]. This latter conclusion is confirmed by the fact that the observed $[OH^-]/[O_2^-]$ depended slightly on the diameter of the sampling orifice. This compares with the ratio $[e^-]/[Y^-]$ being independent of hole size, in line with a relatively slow production of negative ions Y^- by electron attachment.

As a first step, consider only reactions (1) and (2), so that:

$$d[Y^-]/dt = k_1[e^-][O_2][M] - k_{-1}[O_2^-][M]. \qquad (I)$$

This may be expressed as:

$$y = \frac{v}{[e^-]}\frac{d[Y^-]}{dz} = k_1[O_2][M] - \gamma_{OH}^{-1}\frac{[OH^-]}{[e^-]}\frac{k_1[O_2][M]}{K_3[OH]_e}, \qquad (II)$$

with the flame velocity $v = dz/dt$ and $[O_2^-] = [OH^-][O_2]/(K_2[OH]_e\gamma_{OH})$, provided (2) is balanced. All this is checked in Fig. 2*a*, which is a plot of y against $x_1 = \gamma_{OH}^{-1}[OH^-]/[e^-]$. For this, values of y were obtained by numerically smoothing and differentiating[16] the distance profile of $[Y^-]$. It is seen in Fig. 2*a* that y initially rises and is then linear in x_1 from 9 to 16 mm from the reaction zone. The central linear portion yields $k_1 = 3.2\times10^{-34}$ from its y intercept and the different $k_1 = 4.5\times10^{-34}$ ml^2 molecule^{-2} s^{-1} from the slope.

The departures from linearity are understandable in terms of minor contributions from reactions (4)–(6). The inclusion of reaction (4), along with (1) and (2), gives the rate equation:

$$y = k_1[O_2][M] + k_4[H_2O] - \frac{[OH^-]}{[e^-]}\times (\gamma_{OH}^{-1}k_1[O_2][M] + \gamma_{OH}^{3}k_4[H_2O])\frac{1}{K_3[OH]_e} \qquad (III)$$

where $[H]_e/K_4 = [H_2O]/(K_3[OH]_e)$. Letting $r = k_4[H_2O]/k_1[O_2][M]$ be the ratio of the forward rates of reactions (4) and (1), an estimate of r can be obtained from Fig. 2*a* where $y = 0$. This is at $z = 22$ mm from the reaction zone, where $\gamma_{OH} = 1.32$ and $[OH^-]/[e^-]$ has approximately its equilibrium value of $K_3[OH]_e = 0.250$. (This latter observation confirms that our measurements of $[OH^-]$ and $[e^-]$ are free from sampling falsifications[8,13].) Thus, equation (III) may be solved for the derived value of $r = 0.185$, whose magnitude shows electron attachment in (4) to be much less than via (1). In any case, equation (III) becomes:

$$y = (1+r)k_1[O_2][M] - (\gamma_{OH}^{-1} + r\gamma_{OH}^{3})\frac{[OH^-]}{[e^-]}\frac{k_1[O_2][M]}{K_3[OH]_e} \qquad (IV)$$

Figure 2*b* shows a plot of y against $x_2 = (\gamma_{OH}^{-1} + r\gamma_{OH}^{3})([OH^-]/[e^-])$ with $r = 0{:}185$. There is now a more extensive region of linearity from 9 to 24 mm, which yields $k_1 = 6.6\times10^{-34}$ from the y intercept and $k_1 = 6.4\times10^{-34}$ ml^2 molecule^{-2} s^{-1} from the slope, that is, differing by only 3%. The mean value of $k_1 = 6.5\times10^{-34}$ together with $r = 0.185$ gives $k_4 = 7.9\times10^{-17}$ ml molecule^{-1} s^{-1}, which is in excellent agreement with Jensen and Jones's estimate[14], based largely on a room temperature measurement[17] of k_{-4}. The occurrence of points in Fig. 2*b* off the straight line is thought to reflect slight inaccuracies in γ_{OH}, which appears as $\gamma_{OH}^{3} (= \gamma_H)$ in equations (III) and (IV), rather than deficiencies in the kinetic model. For example, the point

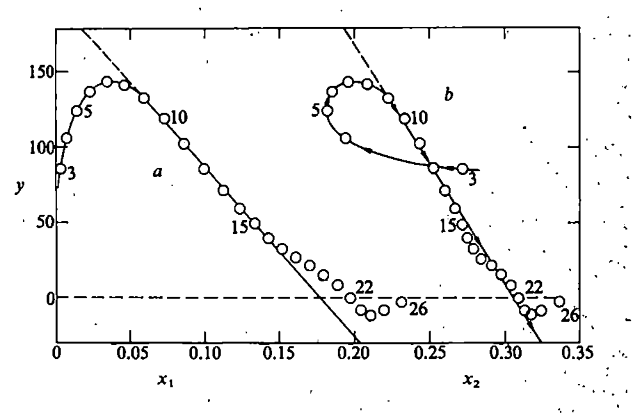

Fig. 2 The data in Fig. 1 plotted as $y = v/[e^-]\times d[Y^-]/dz$ against $x_1 = \gamma_{OH}^{-1}[OH^-]/[e^-]$ in *a* and against $x_2 = (\gamma_{OH}^{-1} + r\gamma_{OH}^{3})[OH^-]/[e^-]$ in *b*. Points are numbered according to their distance from the reaction zone in mm and the arrows in *b* denote the sequence of points at increasing times in the burnt gases.

5 mm from the reaction zone becomes on the straight line, if γ_{OH} there is changed from 2.84 to 3.08, which is just within the error bounds for γ_{OH}. Figure 2*b* shows that *y* is initially small, then increases and finally becomes negative. That $[Y^-]$ first shifts away from and then back through equilibrium is mainly caused by γ_{OH} declining, and consequently electron detachment being initially dominated by (−4), then becoming less important and finally increasingly by (−1).

A detailed examination shows that the effect of including process (5) is to shift those experimental points for conditions near the reaction zone farther away from the straight line in Fig. 2*b*. We thus conclude that the contribution from reaction (5) is insignificant. Moreover, similar reasoning applied to reaction (6) indicates negligible participation, particularly because $[H_2O_2]_e$ is extremely small at flame temperatures. Finally, the derived k_1 and k_4 were found not to depend systematically on either the diameter of the sampling orifice or on the amount of potassium added to the flame. This establishes that our measurements are free from any falsifying perturbations encountered[8,18] with fast reactions proceeding during sampling.

In conclusion, we find $k_4 = 8 \pm 4 \times 10^{-17}$ ml molecule^{-1} s^{-1}, which is very much in line with estimates based on room temperature data[14,17]. Also, the behaviour of $[OH^-]/[O_2^-]$ in Fig. 1 is consistent with $k_2 > 10^{-12}$ ml molecule^{-1} s^{-1}, which is not surprising. On the other hand, our conclusion that $k_1 = 6 \pm 3 \times 10^{-34}$ ml^2 molecule^{-2} s^{-1} is much less than the lower temperature measurements of $k_1 \sim 10^{-31} - 10^{-30}$ for a reaction not expected to be very temperature-dependent[6,7,14]. That reaction (3) is not participating indicates that k_3 must also be much smaller than the estimated[14] value of 3×10^{-31} at ~2,000 K. We can only conclude that three-body electron attachment in a process like (1) or (3) has a surprisingly large negative temperature coefficient.

We thank J. E. Ogden for help with measurements of flame radical concentrations and Dr N. A. Burdett for helpful discussions.

Combined rotating and linear motion effects on the wear of polymers

B. J. Briscoe & T. A. Stolarski

Department of Chemical Engineering and Chemical Technology,
Imperial College, Prince Consort Road, London SW7, UK

The unusually low friction of polytetrafluoroethylene, PFTE, is utilised in many commercial applications[1]. Unfortunately this low friction is often accompanied by rather high wear, and it is generally necessary to modify the polymer, usually by the incorporation of solid inorganic filler particles, to reduce the wear to acceptable levels[1,2]. Although several attempts have been made to establish the mechanism of this improved wear behaviour, the optimisation of filler type, size and concentration remains an empirical exercise, and several relatively simple wear testing machines have been developed to assess prospective materials[3,4]. These tests attempt to reproduce the sliding conditions encountered in practice. A widely used test is the pin-on-disk configuration where a fixed pin of polymer is loaded against a rotating disk. The load and relative velocity are fixed and the pin describes a circular path over the disk surface for a predetermined period, after which the wear is measured, generally by weighing the polymer pin. Important additional variables are the environment, the surface topography of the disk, the temperature and the geometry of the pin[5]. In the process of conducting such a series of measurements we have identified and report here an additional variable which may be of general importance: the radius, *R*, of the path described by the pin on the disk.

Figure 1 shows data for the wear per unit distance, *K*, for specimens of PTFE and low density polyethylene, LDPE, as a function of *R* obtained using a pin-on-disk machine (for experimental details see ref. 6). We observe that *K* is a marked function of *R* for PTFE but not for LDPE. Figure 2 shows the same data and also data for other polymers as well as carbon-filled PTFE. Here, the wear data have been normalised by dividing the $K(R)$ obtained at a particular value of *R* by the value for $K(\infty)$ which is obtained by extrapolating $K(R)$ against $1/R$ curves to $1/R = 0$. The value of $K(\infty)$ corresponds to the wear rate for 'pure' linear sliding. In Fig. 2 the data are presented as the ratio of $K(R)/K(\infty)$ against $1/R$ which has the virtue of superimposing the sets of data for PTFE and linear polythene on two master curves. The sliding velocities, *V*, and nominal contact pressures are constant for each specimen. The disk is cooled by a coolant flow beneath the disk surface and the bulk temperature is ~20 °C (ref. 6). Note that two polymers, polymethylmethacrylate, PMMA, and LDPE, show no radius effect until *R* approaches the radius of the pin. However, for PTFE and a carbon-filled PTFE composite the wear decreases significantly as *R* is decreased. The data for high density polythene, HDPE, and ultrahigh molecular weight polythene, UHMPE, show a similar but less marked effect. Simultaneous measurements of the frictional force have also been made, and these data indicate that where the wear decreases the friction increases.

The common reduction in wear as *R* approaches the pin radius is due to the fact that, although the polymer surface is damaged, the comparatively small relative displacement of the surfaces enables much of the wear debris to be confined in the contact zone. The weight loss from the pin is thus reduced. At larger values of *R* the unusual behaviour of PTFE and, to a lesser extent, the linear polythenes seem to arise from a peculiarity in the pin-on-disk method. Since the pin describes a circular path the motion is complex and may be considered to be comprised of a linear vector, *V*, combined with a pin rotating with an effective angular velocity, ω_p, equal to that of the disk, ω_d. As *R* decreases while *V* is maintained constant, ω_p increases as $1/R$.

It is this angular component which we believe is responsible for the unusual friction and wear behaviour shown by PTFE and the linear polythenes. The reason for this effect is not clear, but the following rationale accounts for the results. PTFE and HDPE have unusual friction and transfer behaviour although the behaviour is more pronounced by PTFE[7,8]. If a PTFE pin is slid linearly at low speeds against a clean smooth surface, the static frictional force is initially high and a relatively thick transfer layer is deposited. Further sliding produces a thinner and more highly orientated film and a lower dynamic frictional force. If sliding is arrested and the polymer pin is then rotated about its load axis by 90°, the initial behaviour is repeated[7]. We have also conducted a series of measurements where polymer spheres of ~8 mm diameter have been subjected to a simul-

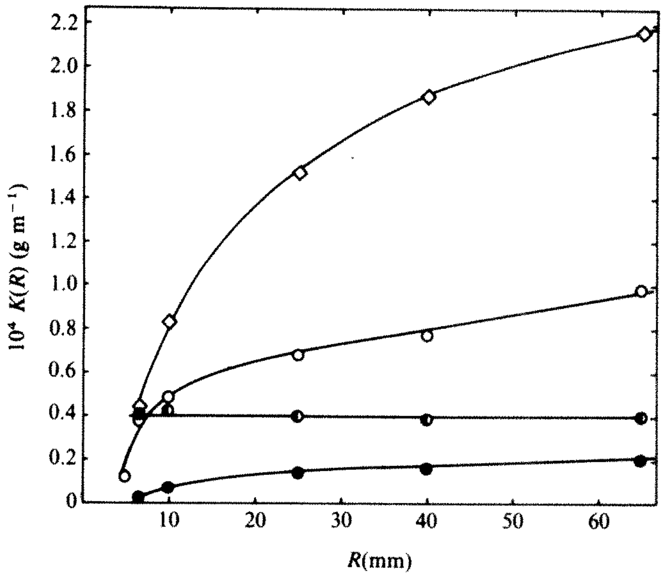

Fig. 1 Rate of wear, $K(R)$, expressed as mass loss per unit sliding distance, as a function of R, the radius of the wear path for PTFE and LDPE. Sliding velocity: 0.5 m s^{-1}; nominal contact pressure: 6×10^5 Pa; counterface temperature ~20 °C; counterface mild steel, roughness ~0.1 μm c.l.a.; pin diameters: PTFE ●, 6 mm; ○, 13 mm; ◇, 20 mm; LDPE ◐, 13 mm (wear rate × 10^2). The wear rate is a marked function of R.

taneous combination of linear and rotating motion in an attempt to reproduce the effective motion of the pin in the wear testing machine. The frictional force in the direction of linear motion was found to be extremely sensitive to the introduction of rotation for PTFE materials and also to a lesser extent for HDPE and UHMPE. The frictional force in this direction typically increases from the low kinetic value to a maximum value close to the static value as the imposed rotational velocity is increased, and it reaches a maximum when the angular velocity is such that the contact area is rotated by $\pi/2$ for a linear travel approximately equal to the contact diameter. This result is consistent with the response when a linear motion is interrupted and an instantaneous $\pi/2$ motion is imposed on the contact. When repeated traversals of the fixed polymer pin are made over the transferred layer, the pin seems to displace the layer readily and a further layer is deposited. This process leads to high wear and there is evidence that the rate of wear is greatly influenced by the magnitude of the adhesion of the transferred layer to the substrate[8,9]; the greater the strength of adhesion the lower the rate of wear. When rotation is introduced during linear sliding the transferred films seem to be somewhat thicker and more tenaciously attached to the counterface for PTFE, although we have no quantitative results. These effects are restricted to sliding on smooth counterfaces and apparently to contacts where either the sliding velocity or the contact pressures have moderate values. For a large apparent contact pressure of ~1.3×10^7 Pa the unusual response decays quickly at sliding velocities in >20 mm s^{-1}. At a more moderate contact pressure of 6×10^5 Pa, which is typical of commercial contacts, the unusual behaviour is maintained to above 2.0 m s^{-1}. When the counterface is rough, for example when the centre line average roughness is ~3.0 μm, the unusual friction behaviour of PTFE is absent in all the contact conditions studied.

In contrast LDPE shows only high friction and thick film behaviour with no orientation effects. This polymer also shows no increase in the frictional force as measured in the linear sliding direction when rotation is imposed. PMMA is similarly insensitive. The special friction and wear behaviour seems to be restricted to 'smooth molecular profile' polymers when they are slid on smooth counterfaces and in no more than moderately intense contact conditions. These effects seem to be associated with reorientation processes occurring in the contact. The introduction of rotation into a linear sliding motion will clearly affect this process and hence produce thicker transferred films. The friction data observed in the pin-on-disk experiment are consistent with this, as are the low speed data. To explain the reduction in wear with small additions of angular velocity we must then assume that the thick unorientated layers adhere more strongly to the substrate than the thinner more highly orientated films[7] and hence a lower wear results. The comparatively low wear of LDPE compared with PTFE and HDPE in comparable conditions is consistent with this hypothesis.

The results on the pin-on-disk machine indicate that the radius effect described may be interpreted if we assume that the polymer pin is effectively rotated as it describes its circular path of radius R. We have conducted a series of measurements where the pin is actually rotated about its load axis while it is in contact with the rotating disk. The direction and magnitude of this pin rotation, ω_p, have been varied over a wide range for a fixed value of R. When the value of ω_p is equal in magnitude to ω_d but rotating in the opposite direction the wear rate of PTFE is observed to have its maximum value. This corresponds to effectively 'pure' linear sliding. If, however, the pin is rotated in the same direction as that effectively induced by the disk's rotation a minimum in the wear rate is observed when ω_p is such that the total pin rotation is equal to a value of $\pi/2$ for a linear travel distance of approximately one contact diameter. For the contact conditions studied (contact pressure 1.5×10^6 Pa, sliding velocity 0.2 m s^{-1}) there is a factor of about 3.5 difference between the maximum and minimum values of these wear rates. Between the two extremes there is a gradual decrease in wear as the amount of rotation is increased. When the amount of rotation is further increased beyond the minimum point the rate of wear increases. We have also observed a significant difference in the nature of the transferred film and the wear debris in these experiments. When the wear is at its maximum the transferred film is thin and the wear debris is highly fibrillar in appearance. At the minimum rate of wear the transferred film is thicker and the wear debris is in the form of the plates. In contrast the rate of wear and the appearance of the transferred layers and wear debris are insensitive to the introduction of imposed rotation for LDPE in similar conditions. These results confirm that the unusual behaviour of PTFE in the simple pin-on-disk experiment probably arises from the introduction of apparent rotation.

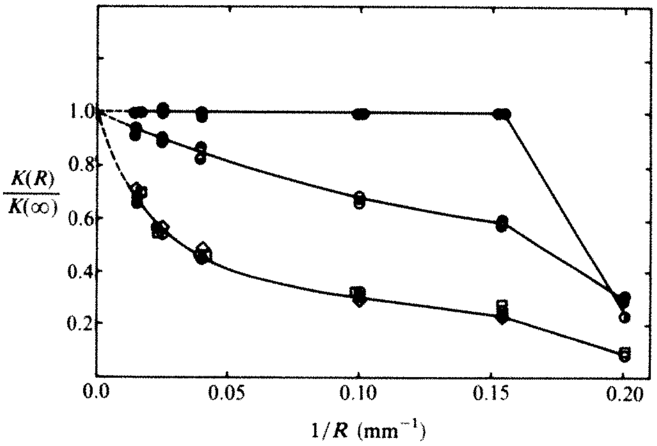

Fig. 2 Normalised wear rate, expressed as $K(R)/K(\infty)$ against $1/R$ where $K(\infty)$ is the estimated wear rate for linear sliding and R the wear track radius. Sliding conditions as for Fig. 1. □, Carbon-filled PTFE 1:5 w/w; ◒, UHMPE; ◑, PMMA; ◓, HDPE; test pin diameters, 13 mm. Other symbols as for Fig. 1. Polymers of the type HDPE, UHMPE and PTFE show a marked reduction in wear as R decreases, while PMMA and LDPE show no effect until R approaches the radius of the test specimen. For PTFE the reduction in wear is of the order of 70% while for HDPE and UHMPE the effect is more modest, approximately 40%. Further reductions are noted when the wear track radius decreases below that of the radius of the pin.

They further emphasise the peculiar sensitivity of this polymer to rotation during sliding and indicate that these effects arise from the disruption of natural orientation processes which are produced during sliding.

Our results have two consequences: at a practical level they indicate the need for caution when measuring the friction and wear of PTFE and, to some extent, HDPE and UHMPE and their composites using the pin-on-disk configuration, and from an academic point of view it introduces a new and interesting variable for probing the friction and wear mechanism of these materials.

First observation of the coil–globule transition in a single polymer chain

Izumi Nishio, Shao-Tang Sun, Gerald Swislow & Toyoichi Tanaka*

Department of Physics and Center for Materials Science and Engineering, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139

The conformations of single polymer chains in solution have been studied extensively since the 1940s. At high temperatures and in good solvents, a polymer has an extended coil configuration, while at low temperatures and in poor solvents a polymer is in a collapsed globule state. The transition between the extended and collapsed state as the temperature or solvent composition is varied was thought to be smooth and continuous, and experiments supported this idea[1]. However, in the 1960s it was suggested[2–4] that the transition between the two configurations, the coil–globule transition, was discrete. We now report the first observations of the single polymer coil–globule transition. The observations were made on polyacrylamide molecules dissolved in acetone–water mixtures.

The mechanism of the transition, as described by Lifshitz[4], is quite similar to that of the gas–liquid transition. The extended polymer corresponds to the gas state, whereas the collapsed polymer corresponds to the liquid state. Many others have contributed to the theory of the coil–globule transition[5–9]. For example, de Gennes[9], using the analogy of the magnetic transition, pointed out that the coil–globule transition of an infinitely long polymer may correspond to a tricritical point. On the experimental side, there have been reports on the temperature dependence of the radius of gyration of polystyrene in cyclohexane[10–13], and on polyacrylic acid in dioxane[13]. In these experiments, however, the existence of the coil–globule transition was not confirmed.

Recently, Tanaka[14] and Fillmore and Tanaka[15] observed the reversible collapse of a covalently crosslinked polyacrylamide network immersed in an acetone–water mixture. The collapse occurred upon changing either the temperature or acetone concentration of the system. The experiments showed that the volume of the gel can change reversibly by a factor of 100 at the transition. This suggests that a single polyacrylamide chain may undergo a coil–globule transition in acetone–water mixtures.

Acetone is a poor solvent for polyacrylamide, whereas water is a good solvent for the molecule. By gradually changing the composition of the mixture, the polyacrylamide molecules can be brought through the transition between the regions of good solvent and of poor solvent. In our experiment, we used monodisperse polyacrylamide polymers of molecular weight $5–6 \times 10^6$ (Polysciences Inc). A single chain of the polymer consists of approximately 8×10^4 acrylamide monomers and has a length of about 24 μm. The concentration of the polymer in solution was less than $10\,\mu\text{g ml}^{-1}$. At this concentration, the mean distance between adjacent polymers, of the order of 1 μm, was much larger than the average polymer size, thus interpolymer entanglements were avoided. An argon-ion laser (Spectra Physics Model 165) at 5,145 Å wavelength was used as a light source. The laser power was approximately 1 W. The correlation function of light scattered from the sample at a 90° angle was measured using a photomultiplier tube and a photon correlator (Nicoli Instruments). All measurements were made at 25 °C. From the decay rate of the correlation function of the scattered light intensity, we determined the diffusion coefficient, D, of the polymer, which is related to the hydrodynamic radius, ξ, of the polymer through the Stokes–Einstein relation[16]:

$$D = kT/(6\pi\eta\xi)$$

where k is the Boltzmann constant, T is the absolute temperature, and η is the viscosity of the solvent.

Figure 1 shows the hydrodynamic radius of the polymer plotted as a function of acetone concentration (open circles). At low acetone concentrations, the radius is large, approximately 500 Å. Near an acetone concentration of 39%, the polymer shows a drastic decrease in hydrodynamic radius to about

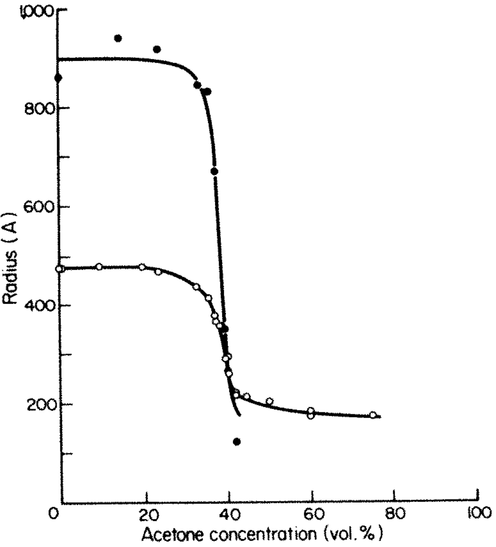

Fig. 1 The hydrodynamic radius of a single polyacrylamide chain, determined by laser light scattering spectroscopy, is plotted (○) as a function of the acetone concentration of the acetone–water mixtures used as solvent. The radius of gyration of the polyacrylamide chain, determined from dissymmetry measurements of the scattered light intensity, is also plotted (●). It was very difficult to determine the radius of gyration for values below 300 Å. Samples were prepared as follows. Polyacrylamide molecules were carefully dissolved in pure water, and gently stirred using a magnetic stirrer. The solution was then left standing for several days to ensure complete dissolution, before adding the solution to the acetone–water mixtures. The samples were then filtered through a 0.4-μm filter before the measurements were made.

0028–0836/79/380208—02$01.00

200 Å. With further increases in acetone concentration, the polymer radius remains constant. We found the transition to be reversible and reproducible.

We also determined the radius of gyration of the chain from the angular dissymmetry of the scattered light intensity[17]. The results are shown in Fig. 1 (solid circles). The coil–globule transition is seen to occur at exactly the same acetone concentration as that seen in the curve of the hydrodynamic radius. The value for the radius of gyration, r_g, is about twice that of the hydrodynamic radius, ξ, in the coil state for the following reasons. First, for chain polymers, the hydrodynamic radius may be smaller than the radius of gyration due to such factors as the nature of the side groups on the polymer chain and the viscosity of the solvent. Measurements on polystyrene in solution[18] have shown ξ to be at least 20% smaller than r_g. The difference would be expected to be even larger for polyacrylamide, as it has much smaller side groups. Second, in our experiments, when r_g becomes higher than 500 Å, the fluctuations in the chain conformation begin to scatter light substantially[19,20]. This makes the apparent diffusion coefficient, calculated assuming that the scattering light intensity fluctuates due only to the translational motion of the polymer, larger than its actual value. Thus, the apparent ξ becomes less than the actual value. It is of interest to investigate further the amplitude and relaxation times of such chain configuration fluctuations.

The observed transition between the coil and globule states of the polymer is quite sharp, but not absolutely discrete. The finite transition width is probably due to the polymer chain comprising only a finite number of monomer units. A chain composed of an infinite number of monomers would be required to observe a discrete transition[4]. It will be important to investigate further the effect the finite size of the system has on the transition.

Thus we have presented direct evidence of the existence of the coil–globule transition in single polymers. The hydrodynamic radius of polyacrylamide chains in solution changes sharply in the transition between the regions of good solvent and of poor solvent. This sharp change in polymer size may function in amplification, switching, and memory at the molecular level and could have potential applications in biology, medicine and chemical engineering.

Basaltic pillars in collapsed lava-pools on the deep ocean-floor

J. Francheteau*, T. Juteau† & C. Rangan‡

Observations of peculiar volcanic objects, made by a submersible on the deep sea floor at a depth of about 2,600 m at and near the axis of the East Pacific Rise during the CYAMEX expedition as part of the RITA Project[1] are presented here. Two basic types of flow forms were observed within the crestal area of the East Pacific Rise: pillow flows and fluid lavas, the latter sometimes overlying massive flows. The East Pacific Rise at 21° N comprises an axial, unfaulted extrusion zone bordered by an extension zone characterised by faulting[2,3]. Pillow flows occupy the innermost or extrusion zone and constitute small elongated volcanic highs. Fluid lavas tend to occur at the edge of the adjacent extension zone in bathymetric lows controlled by normal faults or steep primary slopes of constructional highs. In the 50 × 200 m lows which border the extrusion zone the fluid lava is smooth and lobate surfaces which represent the upper surface of the flow are locally collapsed and reveal the internal structure of the fluid lavas. Where the roof collapse is extensive, layered columnar features are visible and volcanic layering can be seen against the flank of the bordering volcanic highs (Figs 1–3). Similar features have been reported from the Galapagos Rift[4]. The diameter of the approximately cylindrical pillars ranges from 0.5 to 2 m. Some pillars are made of multiple coalescent cylinders. The tops of the pillars are glassy, funnel-shaped and always widening upwards. The pillars were presumed to be hollow from several observations of gashes or openings in the vertical walls of the pillars. This was demonstrated during dive CY 78–19 to the south where a small pillar was toppled by CYANA and subsequent examination revealed a circular canal along the axis of the pillar. The outer surface of the pillars is marked by centimetre-thick glassy, subhorizontal ledges extending several centimetres from the outer vertical surface of the pillars (Figs 2–4). The ledges are spaced every 2–5 cm and show small lava stalactites hanging on the underside of the ledges. Examination of large layered fragments of pillars recovered by CYANA demonstrated that the layering is only a surface feature as it does not extend through the basaltic mass of the pillars. The apparent layering is due to glass ledges adhering to a vertical basaltic pipe. In some rare instances the pillar outer surface showed no ledges and instead a smooth surface corrugated with vertical grooves. Some pillars are inclined or slightly curved; others get narrower towards the base. The pillars are almost totally aphyric and have the same bulk composition as other lava types recovered in the axial zone of the East Pacific Rise at 21° N (ref. 5).

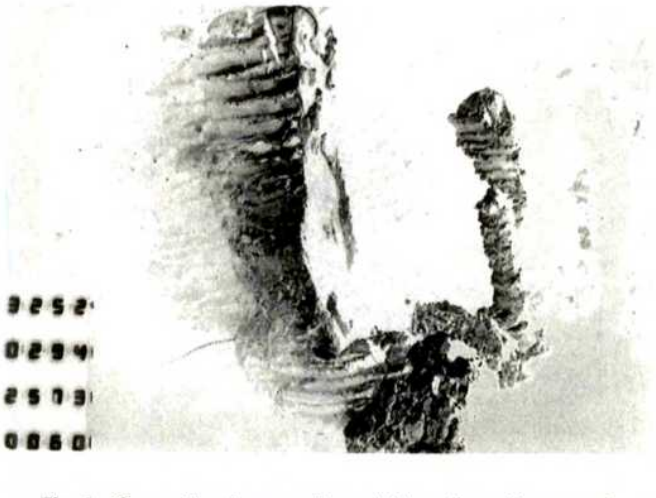

Fig. 1 General landscape: pillars within collapsed lava pond.

0028–0836/79/380209—03$01.00

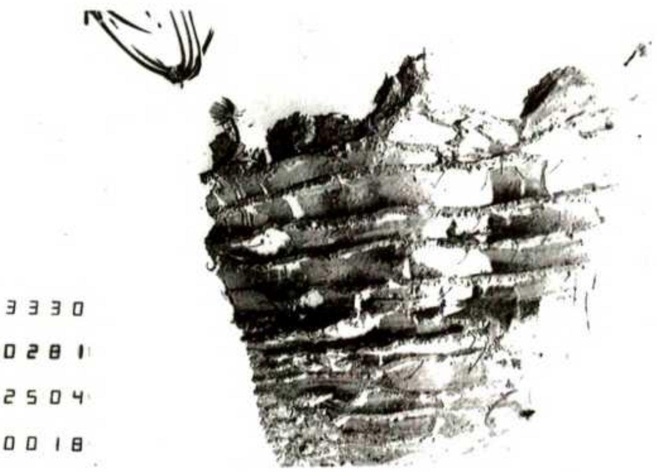

Fig. 2 Detail of a pillar showing the centimetric pseudo layering, with thin and darker salient glass layers projecting from the basaltic surface of the pillar.

The pillars occur in forest-like arrangement (Fig. 3). Their spacing ranges from 0.5 to 3 m and sometimes they coal c, building walls, especially near the edges of the depressions. However, the pillars are not confined to the edges. The flanks of the lows show large segments of undisrupted glass ledges analogous to those observed on the pillar surfaces. In one case (dive CY 78–19) where the fluid flows partially filled a graben, the layered lateral margin could be seen to represent a chilled, 5–10 cm-thick wall plated against the truncated pillow basalts of the normal fault scarp. The chilled margin was partially detached from the scarp surface.

Non-collapsed glassy upper surfaces of fluid lavas surrounding the fields of pillars show that in the depressions, the thickness of the lobate fluid lava roof is about 10 cm. The horizontal dimension of the lobes is of the same order as the pillar spacing and pillars provide roof support at the junction between adjacent lobes. The geometry of the lobate roof junction is analogous to that of the funnel-shaped pillar tops. Pieces of the lobate roof are commonly preserved around the fluid lava depressions and also where they form bridges between adjacent pillars. In most cases the lava pool appears to be concave upward with a slight (a few metres) depression in the middle of the pool with respect to the edges.

The seafloor around the pillars is strewn by rubble made up of pillar fragments and roof slabs. A deeply incised rille-like canyon was observed near the axis of the fluid–lava depression.

These observations lead us to the following interpretations (Figs 5 and 6):

(1) The fluid lavas fill a preexisting depression either controlled by faulting or by adjacent constructional highs. This is proved by inspection of the lateral contact and by the contrast in lava freshness between the fill and the adjacent pillows. The remarkable fluidity of the lavas cannot be ascribed to chemical differences or to temperature of extrusion. It probably reflects the large volume of outpouring which could in turn be a function of a very high spreading rate over a short time span.

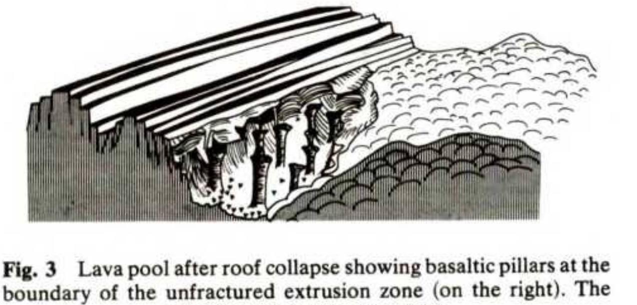

Fig. 3 Lava pool after roof collapse showing basaltic pillars at the boundary of the unfractured extrusion zone (on the right). The pillars are about 10–15 m high.

(2) The seawater which is trapped in the crust under the fluid lava pool is heated and expands (by a factor of 20 for a temperature of 800 °C at a depth of 2,600 m (see ref. 6), forcing its way up through the molten lava in a series of vertical conduits (J. Moore, personal communication) (Fig. 5). The walls of the conduits will be quenched at the boundary between the rising water and the hotter magma. The conduit walls will grow outward from the inner glassy walls of the conduits with time. This explains the hollow pillars found by CYANA. A similar explanation has been put forward by Fuller[7] and Waters[8] to account for the existence of vertical cavities (spiracles) that cut massive lava on the Columbia River Plateau. These authors proposed that water vapour and other gases surge upward into liquid lava that covers marshy ground.

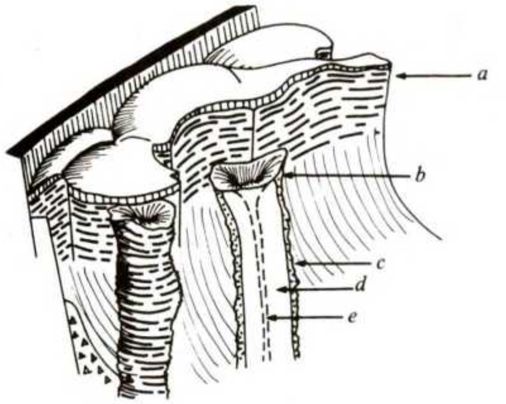

Fig. 4 Detail of basaltic pillar and of edge of magma pool. *a*, Pillar attached to the edge of the pool and capped by smooth lobate fluid lava. *b*, Pillar: funnel-shaped widening upwards Pillar cross-section showing: *c*, lava cooling ledges on outer margin; *d*, massive lava inside pillar wall; *e*, hollow conduit inside pillar.

(3) Before any extensive crystallisation takes place, the lava pool is drained rapidly in successive stages (Fig. 6). This leaves 'bath-tub' rings around the 'cold walls' present in the depression. This includes the pillars and the edges of the pool. This accounts for the apparent layering shown by the pillar samples. The rille-like canyon seen on the floor of the pool may be a drain path. Finally down-drag of either the roof or the outer rigid carapace of the pillars can scrape vertical grooves on the still plastic interior and explain the smooth corrugated outer surfaces of some pillars. A similar mechanism has been proposed by Moore and Richter[9] to explain the vertical striations on the surface of Hawaïan tree moulds.

(4) Solidification on the fluid lava against the cold wall at the bottom of the pool would help to maintain pillars in position after collapse of the roof.

Thus tall, near vertical and hollow pillars with rings of glassy ledges are found in dense arrangement within fossil pools of fluid lava. They are interpreted as the fossil witnesses of both

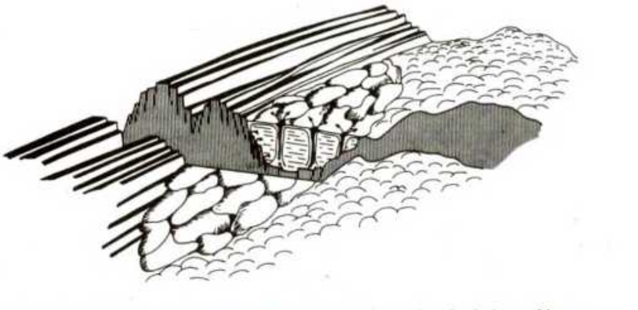

Fig. 5 Reconstruction of magma pool before the draining of lavas and roof collapse. The arrows at the pool surface represent escape of water.

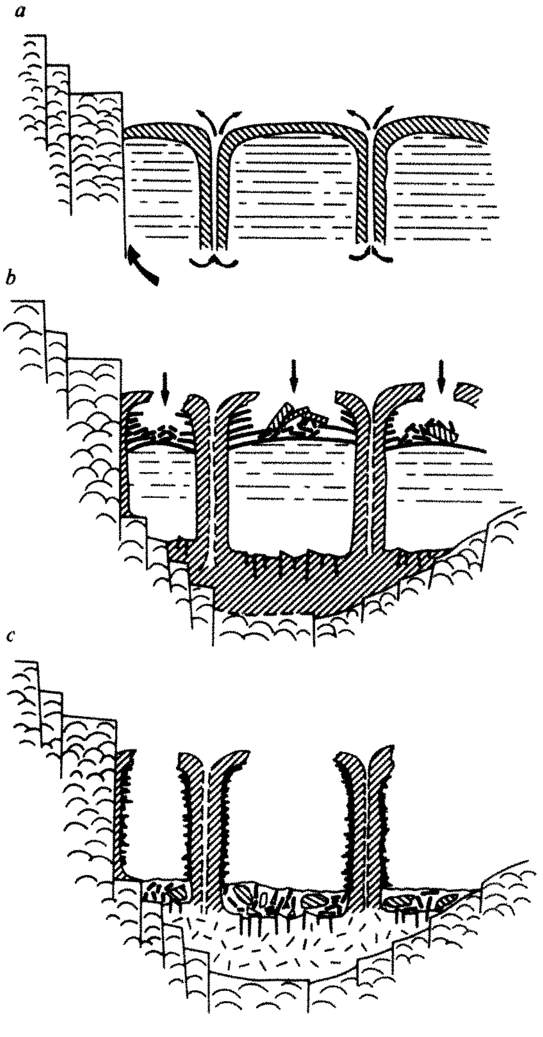

Fig. 6 Inferred evolution of magma pool showing history of pillars and cooling ledges at several stages (see text). *a*, Initial stage of filling of the depression; *b*, beginning of lava pool withdrawal with concomitant roof collapse. *c*, final stage of roof collapse showing isolated pillars standing among coarse rubble.

temporary liquid magma pools which can fill topographic lows and smoth the ridge topography, and of the rhythmic nature and rapidity of the magma pool withdrawal. When drain-off is prevented or when it proceeds too slowly, massive lavas are created.

The fluidity of the lava can be explained if there is rapid emplacement of a large volume of lava resulting in slow cooling of the bulk of the lava pool. The large volume of outpouring may be due to a high 'instantaneous' spreading rate concomitant with a high ascent rate of the lava.

The observations at 21° N show that the size of lava pools increases southward along the axis and thus that the fluid lava regime in the south is predominant over the pillow lava regime. This suggests that instantaneous rates of spreading may be variable along the strike of the mid-ocean ridge.

Planktonic foraminiferal fauna associated with eastern Mediterranean Quaternary stagnations

Robert C. Thunell

Department of Geology, University of South Carolina, Columbia, South Carolina 29208

G. P. Lohmann

Woods Hole Oceanographic Institution, Woods Hole, Massachusetts 02543

Bradley[1] predicted, before any evidence from sediment coring in the Mediterranena Sea, that changing late Quaternary climatic conditions would result in periodic stagnations of the eastern basin and with them, accumulations of organic-rich sediments. Such organic-rich layers from the eastern Mediterranean were subsequently observed in sediment cores by Kullenberg[2] and later named "sapropelitic layers"[3]. Since these initial observations, sapropels have been reported in most studies of Quaternary sediments from the Ionian Sea[4–14]. As a result, there is a great deal of information available concerning the chemical[15–18] and sedimentological properties[13–14], faunal characteristics[19] and temporal[9–11] and spatial[10,12] distribution of late Quaternary sapropels. In the study reported here we have attempted to characterise the planktonic foraminiferal biogeography of such late Quaternary sapropels in terms of the modern distribution of foraminefara in the Mediterranean Sea.

Sapropels are black, organic-rich muds with unusually high concentrations of hydrogen sulphide and iron hydroxide[15]. These sediments seem to be deposited in a particular sequence[13–14], reflecting the transition from open-marine sedimentation (hemipelagic) to that indicative of stagnant conditions. Sapropels are found throughout the entire eastern Mediterranean at depths greater than 800–1,000 m (ref. 12), although the areal extent of individual layers may not be basin-wide[10].

Distinct microfaunal and microfloral assemblages have been described from late Quaternary sapropels. Planktonic foraminiferal[5,9,10,19,21], nannoplankton[20], diatom[16] and pteropod[4] assemblages in sapropels are indicative of reduced surface salinities. For example, high frequencies of *Neogloboquadrina dutertrei*, a planktonic foraminifer preferring low surface salinities[22,24], are generally associated with late Quaternary sapropels[2,5,9–11,21]. Benthonic Formanifera and ostracodes, as well as any evidence of bioturbation, are totally absent from these layers[4,5,10].

Quaternary glacial–interglacial fluctuations have been a fundamental element of even the earliest theories of sapropel formation. Both Bradley[1] and Kullenberg[2] suggested that stagnation of the eastern Mediterranean resulted from lowered surface salinities produced by increased precipitation and runoff during glacial times. Subsequent studies[3,5,7,8,10,11] have also invoked a low salinity surface layer during sapropel formation, but demonstrated that this occurred during interglacial episodes. According to these studies, the flushing of freshwater from the Black Sea into the eastern Mediterranean, possibly combined with increased precipitation, forms a low salinity surface layer that prevents oxygenation of the deep basins and results in accumulation of anoxic sediments. The previously mentioned faunal evidence, together with recent studies on the oxygen isotopic composition of planktonic Foraminifera from sapropel layers, strongly support the existence of a low salinity surface layer[11,19,25].

The present study involves three basic steps: (1) characterisation of the sapropel-associated faunas; (2) comparison of these sapropel-associated faunas with the modern distribution of planktonic foraminifera; and (3) interpretation of the ancient sapropel environment in terms of the modern oceanographic conditions where faunas similar to those associated with sapropels are found. We have simply tried to find out where faunas most similar to the sapropel assemblage live in the modern Mediterranean and determine what is oceanographically unique about these environments.

The sapropel-associated planktonic foraminiferal assemblage was determined by averaging the faunas found in 12 late Quaternary sapropels from cores TR171-27 (33°50′ N, 25°59′ E) and TR172-22 (35°19′ N, 29°01′ E). The averaging process involves a Q-mode principal components analysis of all the foraminiferal frequency data obtained for the sapropel layers. The resulting first principal component (first eigenvector of the pseudo cos θ matrix[26]) represents the 'average sapropel fauna' for the late Quaternary in this region (Table 1). It accounts for $\sim$74% of the variance in the original data, with four species being particularly important (*Globigerinoides ruber*, *Neogloboquadrina dutertrei*, *Globigerina bulloides* and *Orbulina universa*). These species have been previously shown to generally increase in abundance within sapropel layers[5,7,9,10,21,27].

The present-day area distribution of this average sapropel fauna was found by comparing its composition with the planktonic foraminiferal compositions of 66 core top samples distributed throughout the Mediterranean. The core top faunal data, as well as other pertinent information on these samples, has been published previously[28]. The measure of similarity used is cos θ, where θ is the angle between the first principal component and a given sample. It is calculated simply as the product of the unit sample vectors and the unit eigenvector, and it varies from 0 to 1.

The area where core-top faunas are most similar to the average late Quaternary sapropel assemblage is shown in Fig. 1*a* (where similarities are greater than 0.8 on a cos θ scale of 0–1.0).

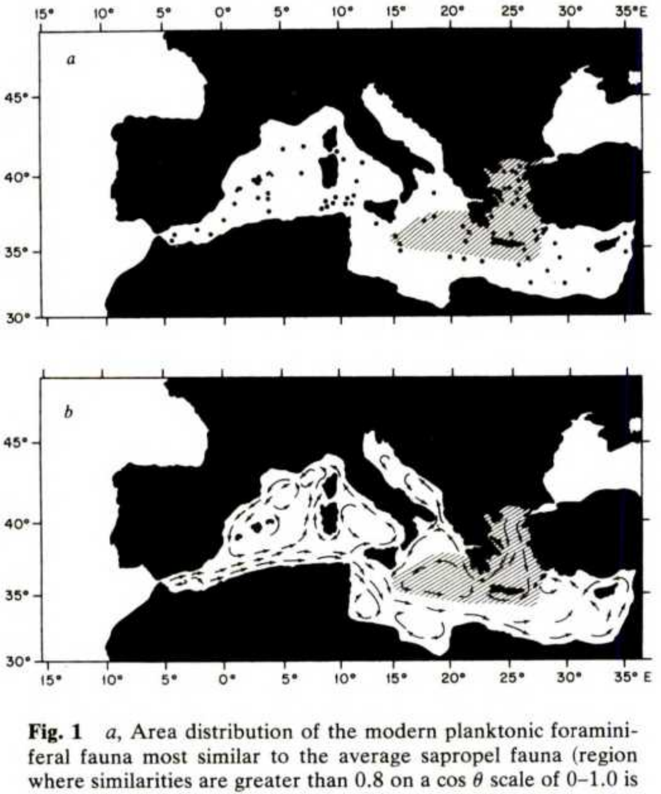

Fig. 1 *a*, Area distribution of the modern planktonic foraminiferal fauna most similar to the average sapropel fauna (region where similarities are greater than 0.8 on a cos θ scale of 0–1.0 is indicated). The core top faunal data is from ref. 28. *b*, Present day surface circulation of the Mediterranena presented by Lacombe and Tchernia[30]. The region containing the modern planktonic foraminiferal fauna most similar to the average sapropel fauna is indicated.

Table 1 Average sapropel fauna derived from a Q-mode principal components analysis of 18 planktonic foraminiferal species from 12 late Quaternary sapropel layers

Species	Per cent abundance
Globorotalia inflata	0.7
Globorotalia truncatulinoides (dextral)	0.0
Globorotalia truncatulinoides (sinistral)	0.5
Globorotalia scitula	1.6
Globigerinoides ruber	29.8
Globigerinoides sacculifera	1.1
Globigerinoides tenellus	1.3
Globigerina bulloides	18.6
Globigerina calida	0.0
Globigerina digitata	0.8
Globigerina falconensis	0.9
Globigerina quinqueloba	1.9
Globigerinella aequilateralis	3.6
Globigerinita glutinata	4.0
Neogloboquadrina dutertrei	24.3
Neogloboquadrina pachyderma (dextral)	1.9
Neogloboquadrina pachyderma (sinistral)	0.2
Orbulina universa	8.8

Abundances are loadings of species on the first eigenvector of the pseudo cos θ matrix[26] and are converted to per cent.

This region of maximum similarity includes the Aegean Sea and the area immediately west of Crete. A comparison of the area distribution of the modern fauna most similar to the average sapropel fauna with the present-day surface circulation of the Mediterranean reveals a close association with surface water that flows out of the Aegean Sea and forms a small gyre in the Ionian Sea (Fig. 1*b*). At present, the Aegean Sea receives a great deal of low salinity water from both river runoff and the Black Sea, with the salinity of the Black Sea water being $\sim$16‰ when it enters the Bosporus[28]. Although this low salinity water mixes rapidly within the Aegean, it is a component of the surface water that flows out of the Aegean. It is within the bounds of this Aegean-derived surface water that the modern planktonic foraminiferal fauna most similar to the average sapropel fauna is confined (Fig. 1*a*).

This biogeographic pattern may give further insight into the mechanism of sapropel formation. If the late Quaternary stagnations of the eastern Mediterranean are due primarily to the input of fresh water from the Black Sea, one would expect to find a low salinity lens extending from the Aegean over the remainder of the eastern basin during times of sapropel deposition. It seems that the biogeographic pattern resulting from a comparison of the modern fauna with the average sapropel fauna is simply a less severe version of what one would expect during periods of stagnation. That is, the present-day surface flow patterns in this region are analogous to those which were associated with times of stagnation. The fundamental difference between the two regimes is that during sapropel formation an intensification of this pattern occurs due to enhanced freshwater input. These results further support the idea that the Black Sea is the major source of freshwater needed to cause stagnation[3,5,19].

We thank Drs W. Berggren, B. Corliss and D. Ross for reviewing the manuscript. Financial support was provided by a Woods Hole Oceanographic Institution postdoctoral fellowship and by NSF grant OCE77-82149 (CENOP).

Miocene tree shrews from the Indian Śivaliks

S. R. K. Chopra, S. Kaul & R. N. Vasishat

Department of Anthropology, Panjab University,
Chandigarh-160014, India

There have been no definite reports of fossil tree shrews although a rib cage from the Tatrot Formation of India has been identified as *Tupaia*[1], and fossil material, including the anterior part of a skull (YGSP 8089) with broken crowns of teeth (I^1–P^4) and a lower left molar (YGSP 8090), from the Middle Śivaliks of Pakistan, has been assigned to the sub-family Tupaiinae (unpublished results by I. Jacobs). The lack of material makes it difficult to assess the evolutionary position of this group, which, together with moles and hedgehogs, is considered to include the most direct modern descendents of the primitive placentals[2]. The living tree shrews have also attracted great interest because of the suggestion that they are related to primates. We report here a maxillary fragment (PUA I5) of the left side with M^1–M^3 and an isolated right lower molar, probably M^2, (PUA I6) recovered from the middle Śivalik deposits of Haritalyangar in Himachal Pradesh, India. We have referred this to the Tupaiinae, although we cannot assign generic and specific names. The following communication[3] describes more substantial material discovered later.

The maxillary fragment (Fig. 1*a*) consists of the molars M^1–M^3 and the posterior roots of premolar P^4. The molars, with the exception of the third, are quadrate in shape and decrease in size from front to back. Each tooth has three prominent cusps—paracone, metacone and protocone—which are connected by crests. The paracone and metacone are V-shaped, well-separated and near the middle of the tooth. Connected by the centrocrista comprising postparacrista and premetacrista, these two cusps form a W-shaped outer (buccal) wall. The disto-lingual aspect of M^1 has a small hypocone which is larger than that on M^2. The hypocone is low and near the neck of the tooth. The buccal portion of the crown of M^3 is broken, but in general this tooth is similar to the first two molars though much smaller. The metacone is also smaller and there is no hypocone on this tooth.

Buccal aspects of M^1 and M^2 display three small styles—parastyle, mesostyle and metastyle. The mesostyle on M^2 is larger than that on M^1. Because the roots are not visible in the maxillary fragment, nothing definite can be said about their nature and disposition. The wear on the occlusal surfaces is considerable.

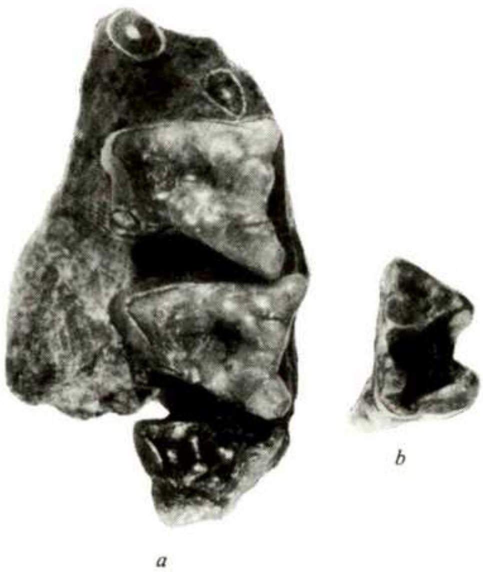

Fig. 1 Occlusal view of PUAI5 and PUAI6 (×7). (The characteristic features of the molar crowns are as identified in Fig. 2*a*.)

The isolated lower second molar of the right side (Fig. 1*b*) has the basic tribosphenic pattern with an elevated trigonid and a low talonid. Three prominent cusps—paraconid, metaconid and protoconid—constitute the trigonid. The talonid basin, which is larger than the trigonid, is bordered by the hypoconid, hypoconulid and entoconid. A moderately developed precingulum is present on the mesial aspect of the tooth. It is supported by two strong roots; the anterior one is broken almost halfway. The tooth shows slight wear due to use.

The maxillary fragment and the isolated M_2 (Fig. 1) have notable general similarities to those of the Tupaiinae (Fig. 2*a*). Like them, the upper molars lack internal cingula on the mesial

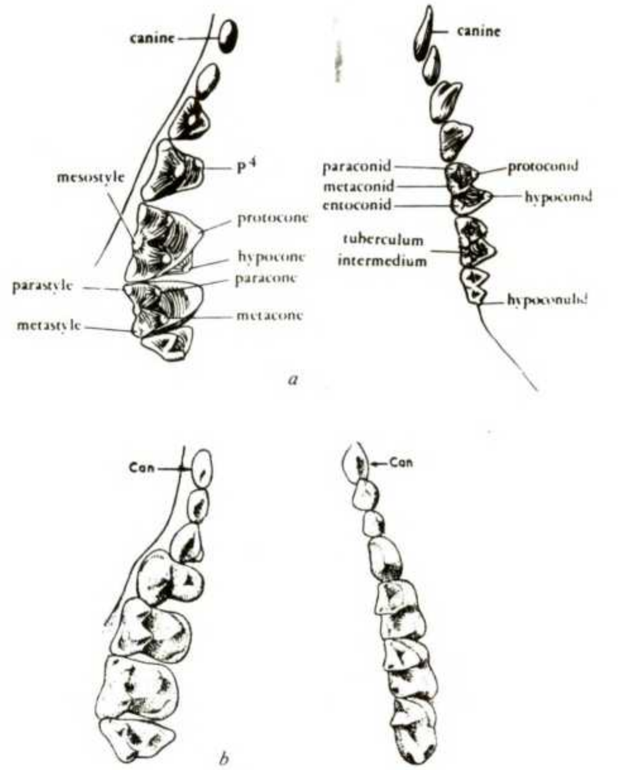

Fig. 2 Occlusal view of the left upper (*left*) and lower (*right*) teeth of *Tupaia glis* (*a*, ×2.2) and *Ptilocercus* (*b*, ×3.4). (*a* After Swindler[8], *b* after Clarke[4].)

0028-0836/79/380213—02$01.00

and distal aspects. The buccal cingulum is visible but the lingual cingulum is not. There is no tuberculum intermedium arising from the entoconid as it does in the lower molars of *Tupaia glis* (Fig. 2*a*). Like most members of the Tupaiidae, and unlike the Soricidae[5], M^1 and M^2 have distinct hypocones. Unlike those of *Ptilocercus* (Fig. 2*b*), the molars have a mesostyle and are not surrounded by a distinct cingulum on all sides[6–8].

A plausible taxonomic placing would need a more complete dentition than is available. However, similarities in morphology with the members of the Tupaiidae outweigh the differences, and, without assigning either generic or specific names at present, we believe that this material warrants its position in the sub-family Tupaiinae.

We thank Baldev Singh for help with photographs.

Śivalik fossil tree shrew from Haritalyangar, India

S. R. K. Chopra & R. N. Vasishat

Department of Anthropology, Punjab University,
Chandigarh-160014, India

We report here a new taxon of fossil tree-shrew from the Śivalik deposits of Haritalyangar in Himachal Pradesh, India. There are no definitive records of fossil tree-shrews, for although two forms, *Anagale*[1] and *Adapisoriculus*[2] have been reported, their affinities with living tree shrews are disputed. Even the taxonomic position of the tree shrews is controversial, with some workers classifying them as primates[3–10] and others disagreeing. Butler[11] has suggested that they should be classified in a new order, Scandentia. The skull fragment (PUA I-3) described here is better preserved and much more complete than previous finds, and it has helped us to extend and confirm the identification of the specimens reported in the preceding communication[12].

Significant contributions to the understanding of anatomy, particularly of the skull and dentition of modern tree shrews have come from Clark Le Gros[5,6], Davis[13], Lyon[14] and Steele[15], and we have adopted the classification of Simpson[16] as follows:

Order	Primates
Superfamily	Tupaioidea
Family	Tupaiidae
Subfamily	Tupaiinae
Genus	*Palaeotupaia* new genus

Type: *Palaeotupaia sivalicus*, new species. [Named as an ancient form of the extant genus *Tupaia*, and after the Śivalik Hills where the fossil was found.]

Generic diagnosis: This is an ancestral and extinct form of the subfamily Tupaiinae with upper dentition 2.1.3.3. It resembles in some characteristics various members of the Tupaiinae, but resembles more closely *Tupaia* sp. in most anatomical details of skull and dentition. In size it resembles *T. minor*, but differs in having a proportionately longer face, less posterior incisive foramena, distinct protocones on P^3, more transverse P^4 and divided mesostyles. It differs from *Ptilocercus* (subfamily Ptilocercinae) in having a supraorbital foramen, well separated lacrimal and infraorbital foramena, lacrimal foramen in a distinct notch and well within the orbital margin and infraorbital foramen above P^3. It also differs in the position of the orbit in relation to the cheek teeth; in having large gaps between the central incisors–I^1 and I^2–and between I^2 and C, and in having a slight space between C, P^2 and P^3. P^3–I^1 is 1.7 × P^4–M^2; there is a large P^3; distinct mesostyles are present, and there is no distinct lingual cingulum or hypocone on the molars.

Palaeotupaia sivalicus new species

Type: PUA I-3 is a well preserved partial skull with left and right P^3–M^2 and roots and alveoli of central incisors, left lateral incisor, right canine, right M^3 and P^2. The right lateral incisor is unerrupted.

Hypodigm: Type plus a maxillary fragment (PUA I-5) of the left side with M^1–M^3, and an isolated right lower molar probably M^2 (PUA I-6) from Haritalyangar, Himachal Pradesh, India.

Horizon and locality: One and a half kilometres north-west of Haritalyangar, Bilaspur district, Nagri Formation,. Middle Śivaliks.

Specific diagnosis: Same as for the genus.

Description: The holotype (PUA I-3) under description is slightly damaged anteriorly. Posteriorly it is broken behind the level of left M^2 and behind the roots of M^3. Left M^2 is also chipped along its buccal margins. The palate appears to be fully ossified. The snout is comparatively long. The skull has a large orbit laterally (better preserved on the right side). Most of the cranial sutures are unclear. The maxillo-premaxillary suture arises from the posterior margin of the incisive foramen. The orbital surface of the maxilla is perforated by the apices of the lingual roots of M^1 and M^2. Ventrally and anteriorly, at the median transverse level of I^2 and behind the central incisors is a pair of large, oval incisive foramena. Along the lateral margin of the skull and immediately above the mesial root of P^3 is the anterior opening of a comparatively medium sized infraorbital foramen. A small foramen is present at the level of P^2. The lacrimal foramen is in a distinct notch which lies well within the orbital margin. At the dorsal surface of the skull there is a distinct supraorbital foramen, part of which is broken. The central incisors appear to be slightly larger than the lateral incisors and are separated from each other by a large gap. Similarly, I^2 is separated from I^1 by a comparatively larger gap. The single-rooted canine is set apart from I^2 by a large diastema. Although the small and single-rooted P^4 is very near to P^3 and C, the gap between the canine and P^2 is bigger than that between P^2

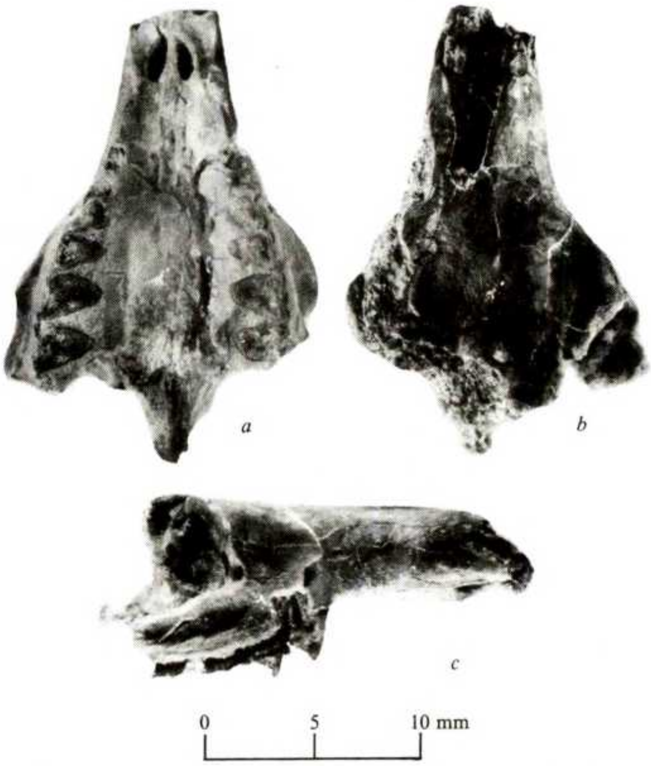

Fig. 1 *Palaeotupaia sivalicus* PUA I-3. *a*, Ventral view of the skull; *b*, dorsal view of the skull; *c*, lateral view of the skull.

0028-0836/79/380214—02$01.00

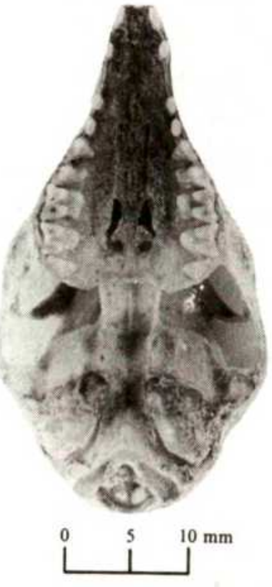

Fig. 2 *Tupaia* sp. Ventral view of the skull.

and P^3. All the teeth from P^3 to M^2 are three-rooted. P^3 and P^4 are bicuspid, the former with a distinct but poorly developed protocone and the latter with quite a prominent and well developed protocone. A complete and fully developed buccal cingulum is also present in P^4. M^1 and M^2 are triangular and dilambdodontic. Along the buccal margin of M^1 and M^2 are three prominent styles, parastyle, mesostyle, and metastyle. There is no hypocone or lingual cingulum on M^1 and M^2.

PUA I-3 differs from *Ptilocercus* in having a supraorbital foramen, well separated lacrimal and infraorbital foramena, a single-rooted canine, large P^3, mesostyles on the molars, no distinct cingulum and hypocones on the molars, and in the size of the incisors position of the orbit in relation to the teeth.

In the subfamily Tupaiinae it differs from *Anathana* which has the orbit (the anterior end) above P^4 rather than M^1. It can be differentiated from *Urogale* by the position of the orbit (above M^2) and the shorter face. It differs from *Dendrogale* in having a comparatively broader snout, single-rooted canine and a more transverse P^4. The specimen resembles *Tupaia minor* in size but differs in having a proportionately longer face, less posterior incisive foramen, distinct protocones on P^3 and more transverse P^4.

On the basis of the differences from various genera of Tupaiinae and the resemblance to Tupaia our specimen is clearly closer to *Tupaia*. But in view of morphological differences and the large age gap between our specimens and the living genus it has been assigned to a new genus and species *Palaeotupaia sivalicus*.

The specimen numbers YGSP 8089 and 8090 may also belong to this new taxon. But this can only be confirmed by further detailed studies of the material.

We thank Professor P. M. Butler for expert comments on the identification, and Dr Louis L. Jacobs for useful discussions.

The significance of beak marks on the wings of an aposematic, distasteful and polymorphic butterfly

D. A. S. Smith

Department of Biology, Eton College, Windsor, Berks, UK

Birds are the principal predators of adult butterflies[1] which they usually hunt on the wing. When successful, they often carry the prey to a perch and attempt to remove the wings with their beaks before eating. If the initial taste is repellant, the butterfly may be allowed to escape more or less uninjured except for a segment (beak mark) removed from its wing. There is evidence that beak-marked specimens are more common (in museum collections) in taxa known to be distasteful or toxic[2]. Based on field data from a population of *Danaus chrysippus* (L.) (Danaidae), a well known distasteful species[3], I have found that large individuals of both sexes are more frequently beak marked than small ones. Comparing two colour morphs (Fig. 1), the rarer one carried more beak marks.

The study was carried out on 235 hectares of grassland with scattered trees at Dar es Salaam, Tanzania. Butterflies were collected with a net, along regular routes, several times a week for 11 consecutive months. Each specimen was marked (to avoid double counting) and the sex, morph, forewing length and beak marks were recorded before release. Relative density was estimated as the number caught per hour.

Of 1,595 butterflies caught, 117 (7.3%) had beak marks. The distribution of beak marks was non-random in two respects. First, beak-marked butterflies were larger ($\bar{x}$ for forewing length = 38.6 mm) than unmarked specimens ($\bar{x} = 37.1$ mm), $d = 4.9$, $P < 0.001$. Second, of the two morphs studied (Fig. 1), *aegyptius* was more frequently beak-marked (12.7%) than *dorippus* (6.0%), $d = 4.1$, $P < 0.001$. Overall frequency of beak marks (y) was positively correlated with size of prey (x_2) ($r_{x_2y} = 0.614$, d.f. 9, $P < 0.05$) and frequency of *aegyptius* (x_3) ($r_{x_3y} = 0.76$, d.f. 9, $P < 0.01$) but not with density (x_1) (Table 1).

Several observers have claimed that birds tend to choose the largest prey available (ref. 4 and refs therein). Therefore, the higher frequency of beak marks on large butterflies might indicate that they are more subject to predation[5]. However, my data show that, although males are significantly larger ($\bar{x} = 38.007$ mm) than females ($\bar{x} = 36.020$ mm) ($d = 12.9$, $P < 0.001$), beak marks are equally frequent in both sexes ($X_1^2 = 0.4$, $P > 0.5$) and independently so in both morphs (for *dorippus*, $X_1^2 = 0.3$, $P > 0.5$; for *aegyptius*, $X_1^2 = 0.6$, $P > 0.3$). This

Table 1 Summary of the data relating to beak-marks on *D. chrysippus* at Dar es Salaam, 1974–5

Month	x_1 Capture rate (N h^{-1})	x_2 Mean forewing length (mm)	x_3 per cent* *aegyptius*	y per cent* beak marked	N
November '74	8.84	34.87	10.0	1.4	76
December	6.32	36.52	5.5	1.4	86
January '75	15.46	37.12	6.2	0.9	206
February	17.19	36.20	6.3	3.1	283
March	19.40	36.10	6.5	9.7	167

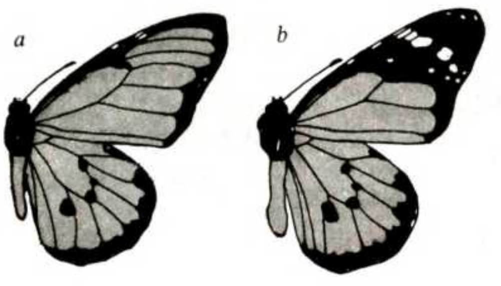

Fig. 1 *Danaus chrysippus* morphs *dorippus* (*a*) and *aegyptius* (*b*). Stippled areas are nut-brown to tawny orange, the remainder being black and white as shown.

unexpected result suggests that the same proportion of each sex is captured: moreover, females, though smaller and presumably weaker, escape predation after capture as readily as males.

The commonest food-plants (all Asclepiadaceae) available to *D. chrysippus* at Dar es Salaam[6] are *Calotropis gigantea*, which contains cardiac glycosides (cardenolides)[3] and *Tylophora stenoloba* which is non-toxic[7]. Butterflies (both sexes) reared on the former in the laboratory are significantly larger[6]. (Cardenolides are ingested by the caterpillar and stored in subsequent stages rendering them unpalatable to birds[3,8–10]. In *D. plexippus*, cardenolides are especially concentrated in the wings[11] where they are likely to be tasted by the bird before the body is fatally damaged.) Thus, the similar proportion of beak marks in both sexes of *D. chrysippus* probably results from the larger individuals of each sex containing more cardenolide, being more distasteful and, consequently, more often rejected unharmed. There is no evidence that the larger size of males serves to protect females.

As the morphs do not differ significantly in size in either sex, they probably use the same range of food-plants[6] and share a common palatibility spectrum. When reared on *C. gigantea* in the laboratory at Dar es Salaam, the two morphs contained similar amounts of cardenolide[3]. Therefore, the higher frequency of beak marking on both male ($X_1^2 = 10.9, P < 0.001$) and female ($X_1^2 = 4.1, P < 0.05$) *aegyptius* is unlikely to result from palatibility differences between the morphs. Moreover, within the range of my data, neither the density of the species as a whole nor the density or frequency of *aegyptius* itself had a significant effect on its beak-mark frequency.

The safety of a model is threatened if it has too many relatively edible mimics[12,13]. At Dar es Salaam, the commonest mimic of *D. chrysippus* is *Hypolimnas misippus* L. (Nymphalidae) which has two female morphs, *misippus* and *inaria*, mimicking *aegyptius* and *dorippus* respectively[14–15]. If *H. misippus* is relatively poorly protected, the *misippus* form, which is much more common than *inaria*[15], may constitute a threat to its *aegyptius* model by rendering the association as a whole relatively palatable. *H. misippus* females are rarely beak marked (3.2%, $n = 94$ in this study), suggesting they are usually consumed after capture. Furthermore, several common species of the well protected family Acraeidae[16] closely resemble *dorippus* and are, therefore, its müllerian co-mimics. *Acraea encedon* alone has forms mimicking both *D. chrysippus* morphs. Thus, *dorippus* is probably better protected and, consequently, relatively avoided and less beak marked by virtue both of its more common müllerian and rare batesian mimics.

A more detailed analysis and discussion of these results will be published elsewhere.

J. Carter Cook Jr

School of Chemical Sciences, University of Illinois, Urbana, Illinois 61801

Extracts of *Brassica napus* L. (rape) pollen (family, Cruciferae) have been reported to produce a novel growth-promoting effect when applied to young pinto bean plants[1,2]. Fractions that are active in the bean second-internode assay[3] give rise to both increased cell elongation and cell division[4]. The validity of these early reports has been questioned because biological activity was not correlated with any one pure compound[5]. Subsequently, we showed that isolation of the growth promoter was complicated by the presence of chromatographically similar, inactive components that were identified as 6-D-glucopyranosyl esters of long-chain fatty acids[6]. We now report the isolation, structure determination and biological activity of this new plant growth promoter, named (22*R*, 23*R*, 24*S*)-2α-3α,22,23-tetrahydroxy-24-methyl-6,7-s-5α-cholestano-6,7-lactone or brassinolide (Fig. 1).

A partially refined 2-propanol extract[7] of bee-collected rape pollen was subjected to successive chromatographic separations on silica gel (chloroform–methanol, 9:1 v/v; toluene–absolute ethanol, 9:1), on C_{18} Hi-flosil (methanol–water, 6:4), and by high-performance liquid chromatography on μ-Bondapak C_{18} (methanol–water, 65:35). The bean second-internode bioassay[3] was used to guide fractonation. Brassinolide (4 mg from 40 kg of pollen) was crystallised (MeOH) and has the following physical properties: $C_{28}H_{48}O_6$ [high-resolution field desorption mass spectrometry shows m/e 481.3489 $(M+1)^+$, calculated 481.3528]; melting point 274–275 °C; IR (KBr) 3,450, 1,690 cm^{-1}, (CH_2Cl_2) 1,720 cm^{-1}; ^{1}H-NMR (C_5D_5N) δ0.72 (s, 3H), 1.03 (d, 6H, $J = 6.3$ Hz), 1.04 (s, 3H), 1.10 (d, 3H, $J = 6.4$ Hz), 1.13 (d, 3H, $J = 6.5$ Hz); ^{13}C-NMR (CD_2Cl_2–CD_3OD, 9:1) δ10.3, 11.9, 12.1, 15.6, 20.8, 21.0 (CH_3), 68.3, 68.4, 71.0, 73.7, 74.8 (C–O), 177.6 (C=O).

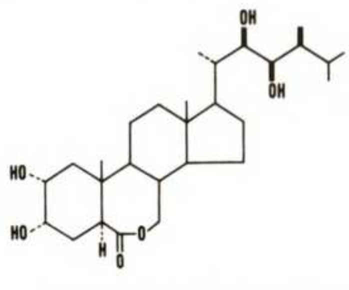

Fig. 1 Structure of brassinolide.

Field desorption mass spectrometry produced fragment ions at *m/e* 463 $(M+1-H_2O)^+$, 445 $(M+1-2H_2O)^+$, 409, 379, 361, 349, 131, 101 and 71. Chemical ionisation mass spectrometry (CI-MS) (isobutane reagent gas) showed ions at *m/e* 481, 463, 445, 427 $(M+1-3H_2O)^+$, 409, 379, 361, 349, 343, 321, 303 and 279. High-resolution electron impact mass spectrometry showed ions for $C_{22}H_{36}O_5$ at *m/e* 380.2561 (calculated 380.2562) and $C_{22}H_{33}O_4$ at *m/e* 361.2398 (calculated 361.2378). Acetylation of brassinolide produced a tetraacetate: *m/e* 649 $(M+1)^+$ by CI-MS. The mass spectral fragmentation pattern is consistent with cleavages along a dihydroxylated side chain and D-ring of a steroid (Fig. 2).

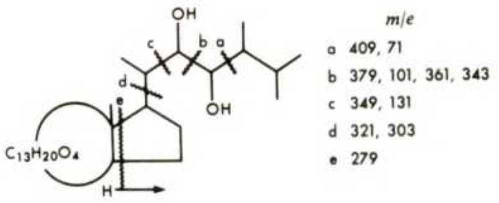

Fig. 2 Mass spectral fragmentation of brassinolide.

The structure of brassinolide was completely established by X-ray analysis of a single crystal which belonged to the monoclinic space group $P2_1$ with $a = 9.88(2)$ Å, $b = 7.63(2)$ Å, $c = 17.98(3)$ Å, and $\beta = 91.9(1)°$. There is one molecule of brassinolide and one molecule of water in the asymmetric unit. A partial structure was obtained by application of the symbolic addition procedure for non-centrosymmetric crystals[8]. The fragment was developed into the full structure by the tangent formula refinement and expansion method[9]. A perspective drawing of brassinolide less hydrogens (Fig. 3) was obtained using experimentally determined atomic positions at an intermediate stage of least-squares refinement. Although only the relative configuration was determined by the X-ray analysis, the enantiomer chosen for Fig. 3 depicts the normal absolute configuration found in natural steroids.

When tested in the bean second-internode bioassay, crystalline brassinolide produced an approximately 200% increase in elongation of the internode over that of an untreated control (Table 1). The increased cell division response was manifested by curvature, swelling and, most dramatically, by splitting of the second internode (Fig. 4) at concentrations of brassinolide as low as 10 ng per plant. Treatment with alkali destroys activity, which is regenerated on acidification.

Table 1 Bean second-internode activity of brassinolide

Brassinolide (ng per plant)	Percentage increase in elongation over untreated control	No. of split internodes
1,000	235	3 of 3
100	189	3 of 3
10	182	1 of 3
1	21	0 of 3

Bioassay was carried out as previously described[3,4]. Brassinolide was dissolved in dichloromethane-2-propanol before mixing with the fractionated lanolin carrier. Three plants were used for each concentration of brassinolide. An equal number of plants treated with lanolin carrier alone served as the control.

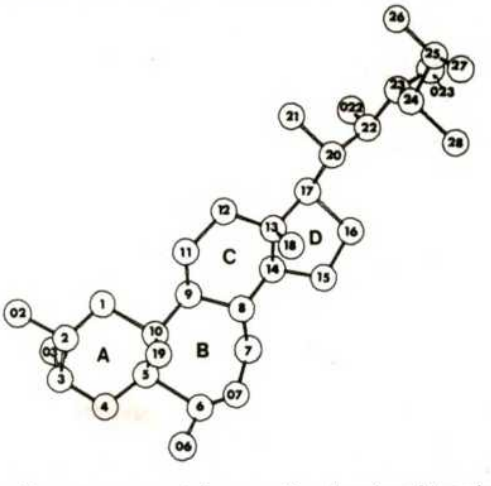

Fig. 3 Computer-generated perspective drawing of brassinolide. Hydrogens are omitted for clarity.

The brassinolide structure can be compared with ecdysone insect moulting hormones[10]. The 2,3-*cis*-glycol of brassinolide is α- rather than β-orientated; brassinolide has a *trans* A/B-ring fusion whereas ecdysones are *cis*-fused; ecdysones have a 7-ene-6-one grouping, whereas brassinolide has a B-ring lactone which is unprecedented in a natural steroid. Although the biosynthetic source of brassinolide is unknown, another C_{28} steroid, 24-methylenecholesterol, comprises 56% of the rape pollen sterols[11]. The 6,7-lactone functionality could originate from a 6-keto steroid precursor through a Baeyer–Villiger-type reaction. Oxidation of 3β-acetoxycholestan-6-one was reported to result in migration of either C-7 or C-5, with the brassinolide-like 6,7-lactone predominating[12].

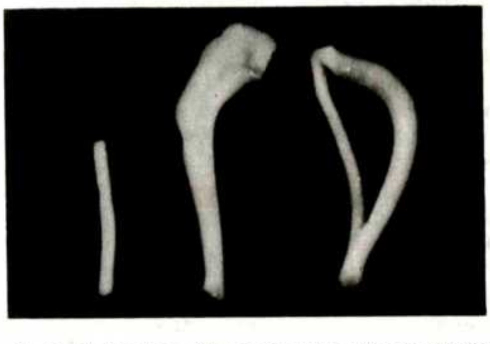

Fig. 4 Excised pinto bean (*Phaseolus vulgaris*) second internodes illustrating from left to right: untreated control; extremely swollen brassinolide treated; split brassinolide treated.

We thank D. W. Spaulding, M. V. Wakeman and B. C. Weathington for technical assistance, Dr D. Weisleder, W. R. Lusby and Dr H. Fineold for providing some of the spectral data.

Loss of immune competence with age may be due to a qualitative abnormality in lymphocyte membranes

Robin E. Callard* & Antony Basten

Immunology Unit, Department of Bacteriology, University of Sydney, NSW, 2006 Australia

Robert V. Blanden

John Curtin School of Medical Research, Australian National University, Canberra, 2600 Australia

The loss of immune function which occurs with age has until recently been attributed to depletion of immunocompetent cells[1–3]. However, studies from our laboratory[4–6] have indicated that the age-related decline in immune responsiveness is better explained by a qualitative rather than a quantitative defect at the level of both T cells and B cells. This conclusion was derived from experiments in which immune function was assessed in relation to the number of responding cells. Thus, lymphoid tissues from old and young mice were found to contain comparable numbers of T cells and B cells despite a 10-fold or greater difference in their antibody-forming potential and mitogenic activity. Furthermore, selective depletion of reactive subpopulations was excluded by the demonstration of similar proportions of mitogen and antigen-binding cells in lymphoid tissue from old and young mice. If the number of cells is normal in old animals, but their function is impaired, it is possible that the decline in immune competence with age may be due to a metabolic or structural abnormality, perhaps affecting the cell membrane and preventing the cell from responding normally to exogenous signals. We have therefore investigated whether any difference could be detected in membrane-associated antigens of lymphoid cells from old and young mice of the same strain. We report here that new or altered antigenic determinants seem to be expressed on the surface of lymphocytes from old mice. These might interfere with the normal immunological activities of such cells, and so perhaps explain their reduced immune competence.

Three separate techniques were used in our studies. First, spleen cells from six young (3–4 months), C57BL/6J mice were cultured with spleen cells from six syngeneic old (24–30 months) mice of the same sex in one-way mixed lymphocyte reactions (MLRs). Cells were prepared separately from each mouse and cultured in all possible responder-versus-stimulator combinations. As shown in Table 1, except for three young→old combinations, spleen cells from each of the six young donors responded to spleen cells from each of the six old mice. Conversely, cells from each old mouse responded to stimulator cells from each young donor. At no time was any response obtained in young→young and old→old combinations. These findings suggest that cells from old mice possess cell-surface determinants which can stimulate proliferation of young cells and vice versa. This observation was confirmed by the demonstration of a similar young→old MLR with spleen cells from another strain, CBA/Ca/T$_6$ (Table 2). Furthermore, the addition of polyethylene glycol, which potentiates weak MLRs[7], significantly enhanced the young→old syngeneic MLR of cells from both C57BL/6J and CBA/Ca mice (Table 2). This supports the notion that the response obtained in young→old combinations of syngeneic cells represents a true MLR elicited by weak antigenic differences.

The second approach used for the detection of differences in membrane-associated antigens involved raising an antiserum to lymphoid cells from old mice in young syngeneic recipients (young anti-old). This young anti-old serum bound to 7–8% of spleen and lymph node cells from old mice but to only 1–2% of lymphoid cells from young mice (Table 3). Neither young anti-young control serum nor normal sera collected from both groups of recipients before immunisation bound to more than 2% of cells from old or young mice; this is no greater than the number of cells which label with protein A alone. It may be due to the presence of protein A antigen-binding cells or binding of protein A to membrane-associated IgG which is normally present on 1–2% of normal mouse spleen cells[8]. The ability of young anti-old serum to recognise determinants on old lymphoid cells was confirmed by complement-dependent cytotoxicity by the method of Boyse *et al.*[9] (Table 3).

Table 1 Syngeneic one-way mixed lymphocyte reaction between spleen cells from old and young mice

6	4	4	4	4	5	4	0	0	0	0	0	—

Spleen cells were prepared separately from six young and six old C57BL/6J mice of the same sex and cultured in all possible combinations in a one-way MLR. Quadruplicate cultures were carried out in Linbro microtitre trays (Flow Laboratories). Each well contained 5×10^5 stimulator cells and 5×10^5 responder cells in 0.2 ml medium RPMI 1640 (GIBCO) containing 2.5% fetal calf serum (FCS) (Flow Laboratories), 5×10^{-5} M 2-mercaptoethanol, 20 mM HEPES (Flow Laboratories), 2 g l^{-1} NaHCO$_3$, 60 μg ml^{-1} penicillin and 100 μg ml^{-1} streptomycin. Cell division was prevented in stimulator cells by exposure to 1,500 rads irradiation from a ^{60}Co source. Cultures were incubated at 37 °C in an humidified atmosphere of 5% CO$_2$ in air for 48 h, pulsed with 0.5 μCi of ^{3}H-thymidine and collected 24 h later with a Skatron automatic harvester. Incorporation of ^{3}H-thymidine was determined by counting in 0.5% diphenyloxazole/toluene scintillant using an LKB Wallac 81000 liquid scintillation counter. Counts were corrected for efficiency and quenching and expressed as d.p.m. The results are expressed in significant ($P<0.05$) d.p.m.$\times10^{-3}$ above background (–). Background counts were obtained from cultures of spleen cells with irradiated cells from the same animal and were generally less than 5,000 d.p.m. Cultures in which d.p.m. were not significantly above background are expressed as 0. It can be seen that in all but three combinations, cells from each young mouse (young 1–6) responded significantly above background to cells from each of the six old donors. Similarly, cells from each of the six old donors (old 1–6) responded to young but not old cells.

The third group of experiments was designed to test whether the new determinants expressed on old cells might involve antigens of the major histocompatibility complex (MHC), in view of their known importance in modulating immune responsiveness. Reciprocal skin grafts were therefore exchanged between old and young C57BL/6J mice of the same sex. These, however, remained intact for longer than 60 d, suggesting that any modification of cell-surface components with age did not result in significant alteration to either major or minor histocompatibility antigens involved in graft rejection. Possible changes in H-2K and H-2D antigens were further tested for by using an 'H-2-restricted' cytotoxic T-cell response to viral infection[10]. Cytotoxic T cells specific for H-2K or H-2D plus viral antigens were generated in young C57BL/6J mice. These cells lysed virus-infected peritoneal macrophage target cells from old and young mice with similar efficiency (Table 4). As this assay is very sensitive to qualitative changes in H-2K or H-2D antigens caused by mutations[11,12], the negative results obtained

Table 2 Enhancement of syngeneic young→old MLR with polyethylene glycol

Source of spleen cells used in syngeneic MLR	Polyethylene glycol added No	Yes
C57BL/6		
Young→old	2,700±484	8,100±1,750
CBA		
Young→old	9,900±1,300	14,370±3,900

Syngeneic young→old MLRs using spleen cells from two strains of mice were carried out with and without 5% polyethylene glycol, which is known to enhance weak MLRs. Results are expressed as d.p.m. above background counts obtained from young→young MLR cultures. Young mice were aged 3–6 months and old mice 24–30 months.

suggest that an age-related change in H-2K or H-2D antigens is unlikely, but do not exclude alterations in I-region antigens which could explain the stimulation seen in the MLR experiments (Tables 1, 2).

The above findings suggest that new or altered antigenic determinants are expressed on the surface of lymphoid cells from old mice. Antigenic differences between populations of syngeneic lymphocytes have also been reported previously in other systems. For example, cell-mediated cytotoxicity has been obtained in female mice against male-specific (H–Y) antigens[13], although such an explanation has been excluded in the present study by the exclusive use of mice of one sex. In addition, mixed lymphocyte reactivity has been demonstrated with combinations of neonatal thymocytes and syngeneic adult spleen cells[14], which is consistent with the appearance of new antigens during cellular differentiation. More recently, Gozes *et al.*[15] have demonstrated a syngeneic graft-versus-host (GvH) response induced in popliteal lymph nodes of young C57BL/6 mice by footpad injection of syngeneic spleen cells from old donors. This finding, as well as the young→old syngeneic responses reported here, could represent an autoimmune response to 'self' antigens or a response to new antigenic determinants on old lymphoid cells. Such new antigenic determinants could have arisen in various ways; for example, by changes in the cholesterol/phospholipid ratio in the plasmalemma (of the type reported by Rivnay *et al.*[16]) which alters membrane viscosity, disturbs normal lymphocyte function and may expose hidden antigenic determinants, or by insertion, into the lymphoid cell membrane, of altered proteins arising by somatic mutation or from frequent errors in protein synthesis, both of which have been postulated as causes of cellular ageing[17,18].

Table 3 Specific binding and complement-mediated cytotoxicity of young anti-old serum against lymphoid cells from old mice but not young mice

		% Of lymphocytes labelled with:		
Donor mice	Source of cells	Young anti-old serum	Young anti-young serum	Normal mouse serum
Old	Spleen	7.5±1.2*	2	2
Old	Lymph node	6.8±2.0	2	2
Young	Spleen	2	2	2
Young	Lymph node	2	2	2
		% Of lymphocytes killed with:		
		Young anti-old serum	Young anti-young serum	Normal mouse serum
Old	Spleen	14.2±1.2	7.0±0.6	6.0±0.6
Young	Spleen	7.0±1.3	6.4±1.1	6.0±0.8

Antisera specific for old lymphoid cells were raised in syngeneic young recipients of the same sex by six injections of 10^7 pooled spleen and lymph node cells from old C57BL/6J donors given intraperitoneally at weekly intervals. The first, third and fifth injections were given as an emulsion in Freund's complete adjuvant, and viable cells were used on the remaining occasions. A control serum (young anti-young) was prepared in the same way except that young spleen and lymph node cells were substituted for old cells in the immunisation regime. Both antisera were collected 7 d after the final injection. All sera were tested on lymphoid cells from syngeneic mice of the same sex. Specific binding of anti-lymphocyte antibodies was determined autoradiographically, using ^{125}I-labelled protein A, which binds to the Fc portion of immunoglobulin[23]. Briefly, 5×10^6 spleen or lymph node cells were incubated with 20 µl of antiserum in 100 µl of medium 199 containing 0.5% bovine serum albumin (Commonwealth Serum Laboratories) and 15 mM sodium azide for 30 min on ice. After two washes, the cells were incubated with 0.5 µg of ^{125}I-protein A (protein A obtained from Pharmacia and iodinated by the method of Greenwood *et al.*[23] to a specific activity of 10 µCi per µg) in 0.4 ml medium. Unbound label was removed by centrifugation and the cells smeared on gelatin-coated slides. Slides were dipped in Kodak NTB2 emulsion and exposed for 10–21 d at 4 °C and then developed in Kodak D19. The cells were stained with Giemsa and the proportion of labelled small mononuclear cells determined from counts of 1,000 cells per slide. Complement-dependent cytotoxicity was carried out according to the method of Boyse *et al.*[9].

Table 4 Lysis of ectromelia virus-infected peritoneal macrophages from old or young C57BL/6J mice by immune spleen cells from young syngeneic donors

	^{51}Cr Release		
Source of† target cells	Water lysis	Spontaneous lysis	Lysis caused by immune spleen cells
Virus-infected macrophages from old mice	93.5±0.5	34.5±2.0	72.4±2.1* 51.7±3.7*
Control (uninfected) macrophages from old mice	90.1±1.1	22.8±1.2	21.9±0.1 27.0±0.8
Virus-infected macrophages from young mice	92.8±1.4	33.6±2.3	79.3±0.8 46.4±2.2
Control (uninfected) macrophages from young mice	87.4±2.2	24.0±0.8	24.4±1.5 24.7±1.0

* Results obtained from two individual immune mice given 10^4 plaque-forming levels of ectromelia virus intravenously 5 d previously. The killer : target ratio was 20 : 1 and the assay was run for 16 h.

† Macrophages were infected with 40 plaque-forming units of virus for 1 h at 37 °C and left for 3 h before addition of immune spleen cells as described in detail elsewhere[11].

The nature of the new antigenic determinants detected on lymphoid cells from old mice is unknown but the current experiments do shed light on some of the possibilities. The lack of skin graft rejection between old and young mice and the failure to detect differences in cytotoxic T-cell activity (Table 4) argue against alterations in K or D antigens of the MHC. However, neither experiment excludes changes in Ia or M locus antigens which may not give rise to graft rejection. Consistent with modifications in I-region determinants is the finding of mixed lymphocyte reactivity between old and young cells from two different strains of mice (Tables 1, 2). Moreover, further evidence suggests altered expression of Ia antigens in old mice. For example, macrophages from old mice are abnormal in their ability to function as stimulator cells in an allogeneic MLR[19] and an increase in I-J-bearing T cells corresponding to the presence of T-cell suppressors has been detected in old mice (R.E.C. *et al.*, in preparation). An alteration in I-region products with age could explain the decline in lymphocyte function with age, as Ia antigens have a key role in cellular interactions of the immune response. Also, modified Ia antigens may contribute to the high incidence of neoplasia and autoimmunity in the aged. This is supported by the finding of Gleichmann *et al.*[20] of an increased incidence of lymphomas and autoimmunity in chronic GvH disease involving I-region differences only. In addition, the rise in I-J-bearing suppressor cells may further exacerbate the development of tumours[21]. These membrane changes may also explain the high incidence of autoimmune disease in the aged: insertion of a new, non-self, antigen onto the lymphocyte cell surface could allow T-cell help to be expressed for antibody responses to other, self surface antigens. The alternative explanation of autoimmune reactivity to self antigens resulting from a loss of T-cell suppressor function seems less likely because an increase rather than a decrease in T-cell suppressor activity occurs in old mice[6,22]. Whatever the exact nature of the new antigen determinant on old lymphoid cells, it is clear that it may profoundly affect normal immune functions. Furthermore, accumulation of qualitative abnormalities of this kind in other somatic cells may account for ageing in a wide variety of higher organisms.

This work was supported by grants from the National Health and MRC of Australia and the University of Sydney Cancer Research Funds. We thank Dr I. F. C. McKenzie for doing the skin grafts.

Immunity to human haematopoietic stem cells

Robert Peter Gale & Caprice Rutkosky Moran

UCLA Bone Marrow Transplant Team, UCLA School of Medicine, Center for the Health Sciences, Los Angeles, California 90024

Graft rejection is an important problem in human bone marrow transplantation, with a 25–60% incidence in grafts between HLA-identical siblings[1–6]. In mice, two models of rejection of bone marrow grafts have been described: T-lymphocyte-mediated immunity and hybrid resistance (for reviews see refs 7, 8). The first model involves the recognition of foreign histocompatibility (H-2) antigens by selected subsets of T lymphocytes. These antigen-reactive cells undergo clonal expansion and differentiate into cytotoxic effector cells which mediate graft rejection. In the hybrid resistance model, mononuclear cells, probably identical to natural killer (NK) cells, react against haematopoietic histocompatibility antigens on parental marrow cells[9]. Cells involved in hybrid resistance exhibit 'spontaneous' cytotoxicity to disparate haematopoietic cells and, in contrast to T-lymphocyte-mediated immunity, do not require a sensitisation phase before differentiating into cytotoxic effector cells. The mechanism of graft rejection following bone marrow transplantation in man is unknown. In transplants between HLA-identical siblings the target antigens of graft rejection are not HLA or antigens closely linked to the major histocompatibility complex (MHC). To study the problem of graft rejection in man we developed and describe here an *in vitro* model to detect immunity to haematopoietic stem cells committed to granulocyte–macrophage differentiation (CFU-C; colony-forming unit culture). We found that human peripheral blood and bone marrow but not thymus contain a population of cells which are cytotoxic to haematopoietic stem cells following *in vitro* sensitisation. The effector cell population is not a conventional T or B lymphocyte, monocyte–macrophage or NK cell.

The model system is shown in Fig. 1. Peripheral blood mononuclear cells (PBMC) were co-cultivated with irradiated bone marrow cells for 5–7 days. Sensitised PBMC were recovered and incubated with fresh, unirradiated bone marrow cells for an additional 16 h after which the PBMC–bone marrow mixture was suspended in semi-solid agar and plated into Petri dishes over an underlayer containing human colony-stimulating activity (CSA). Granulocyte–macrophage colonies (CFU-C) were counted 7–14 days later using an inverted microscope[10,11].

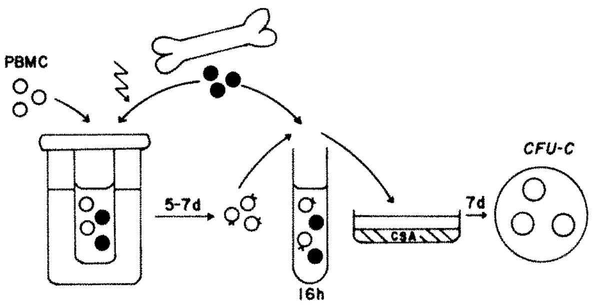

Fig. 1 Experimental model of immunity to granulocyte–macrophage progenitors (CFU-C). Peripheral blood mononuclear cells (PBMC), obtained by Ficoll–Hypaque density centrifugation of venous blood, were resuspended in McCoys 5A medium, 20% fetal calf serum (FCS) and 1% penicillin–streptomycin (PS). Bone marrow from normal donors was obtained by needle aspiration from the posterior iliac crest into syringes containing preservative-free heparin. A leukocyte-rich bone marrow cell population was prepared by centrifugation in Wintrobe tubes at 1,600*g* for 10 min. 10^6 PBMC (0.5 ml) were co-cultivated with an equal number of irradiated bone marrow cells (1,500 rads, Gammacell-220 ^{60}Co-source; rate, 3,200 rad min^{-1}) in Marbrook flasks for 5–7 days at 37 °C in a 7.5% CO_2 atmosphere. Sensitised PBMC were recovered, washed and resuspended in McCoys 5A, 20% FCS and 1% PS. Sensitised PBMC (10^6, 1 ml) were cultured with an equal number of bone marrow cells in 16 × 125 mm plastic tubes for 16–24 h at 37 °C, 7.5% CO_2 atmosphere. Cells (2×10^5) were then diluted in 0.3% agar in McCoys 5A with 15% FCS and plated over white blood cell underlayers in 0.5% agar in Petri dishes which were incubated for 10 d at 37 °C. Colonies of ⩾40 cells were counted using an inverted microscope[10,11].

Data were expressed as the $\bar{X} \pm$ s.e.m. of triplicate cultures and were analysed by paired t-test or corrected χ^2 analysis as indicated. Representative data of five experiments are shown in Fig. 2. Normal human marrow has a cloning efficiency of 104 ± 9 CFU-C and normal PBMC less than 10 CFU–C per 2×10^5 cells plated in these conditions. The addition of PBMC co-cultured with autologous bone marrow to fresh, unirradiated bone marrow from unrelated donors consistently increased the number of CFU-C, probably related to CSA release. In contrast, PBMC sensitised to allogeneic bone marrow consistently inhibited the CFU-C in fresh bone marrow from donors identical or unrelated to the donor of the sensitising cells (Fig. 2). No CFU-C inhibition was observed when bone marrow from the PBMC donor was used as a target or in cultures between genetically identical twins. These data exclude a nonspecific effect of inhibition of CFU-C by *in vitro* sensitisation

The interaction between sensitised PBMC and target CFU-C is time and dose dependent and requires cell–cell contact (Fig. 3). Twenty per cent inhibition of CFU-C was observed after 2–4 h and 80% after 16 h of secondary culture. A 2 : 1 ratio of PBMC to bone marrow usually resulted in a 70–80% inhibition of CFU–C. CFU-C inhibition was not observed when sensitised PBMC were separated from target bone marrow cells by either a Nucleopore or Millipore membrane (control 104 ± 6; co-culture 22 ± 3; separated culture 97 ± 7).

Cell-mediated inhibition of CFU-C was relatively unaffected by depletion of T lymphocytes by anti-thymocyte globulin

0028-0836/79/380220—03$01.00

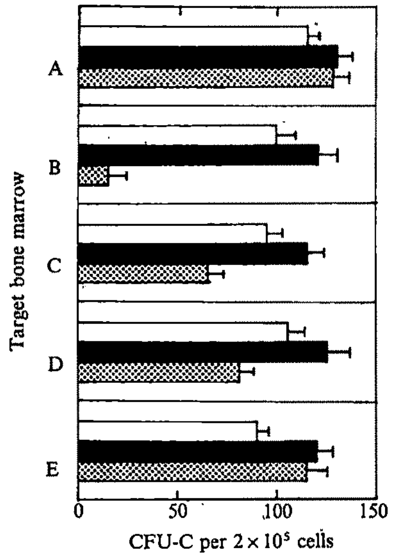

Fig. 2 CFU inhibition by sensitised effector cells. PBMC from individual A were sensitised to autologous bone marrow cells (black bars) or to bone marrow from an unrelated individual B (stippled bars). The sensitised cells were then co-cultured with fresh bone marrow cells and CFU-C determined. Target bone marrow from A and B and from three unrelated individuals (C, D, E) were also tested (ordinate). CFU-C content of the bone marrow from each donor without addition of sensitised effector cells is indicated by the clear bars.

Table 1 Effects of mononuclear cell subpopulation on CFU-C

	Mononuclear cell sub-population			
	T	B	M	NK
Control	86±4	112±7	96±7	75±4
Sensitised PBL	30±2	32±3	20±3	17±2
Depleted	32±5	26±3	17±5	33±6
Enriched	93±6	102±5	120±10	102±7

The CFU-C assay was carried out as described in Fig. 1 legend. PBMC from HLA-mismatched individuals were co-cultivated and tested for inhibition of bone marrow cells from the same donor as the sensitising PBMC. Results are expressed as follows: control, autologous PBL co-cultures with target bone marrow cells ($A \times A_x \rightarrow B$); sensitised, allogeneic PBMC co-cultures with target BM ($A \times B_x \rightarrow B$). HLA-identical siblings were used in the experiment involving T lymphocytes. In other experiments HLA-mismatched, unrelated donors were used. Sensitised PBMC were fractionated using techniques described in Fig. 4 legend. Subpopulations were depleted or enriched for T lymphocytes (E-rosettes), B lymphocytes (nylon-wool column) or macrophages (adherence). NK cells were isolated by fractionation on an immune complex monolayer as described elsewhere[22]. Results are expressed as CFU-C per 2×10^5 cells plated.

(ATG), or removal of sheep erythrocyte rosette-forming cells (E-RFC); by removal of B lymphocytes by nylon wool columns or with anti-B-lymphocyte antisera; or by removal of monocyte–macrophages by phagocytosis of carbonyl ion or adherence to plastic surfaces (Fig. 4). Concentrations of silica and carrageenan that completely inhibited NK activity also had no effect on PBMC-mediated CFU-C inhibition. Furthermore, purified populations of T and B lymphocytes, monocyte–macrophages and NK cells showed no inhibition of CFU-C in identical conditions (Table 1). Bone marrow-derived mononuclear cells but not thymocytes could also serve as a source of effector cells in this assay (data not shown). These data indicate that the effector cell is probably not a conventional T or B lymphocyte, monocyte–macrophage or NK cell.

The target antigen(s) on CFU-C recognised by sensitised PBMC is unknown. To evaluate the role of HLA antigens, we studied five pairs of HLA-identical siblings. Figure 5 shows representative data. CFU-C inhibition was reproducibly demonstrated in four of the five pairs of siblings, indicating that HLA antigens are not the primary target of CFU-C inhibition. In most instances, the degree of CFU-C inhibitions between HLA-identical siblings was not as great as that observed between HLA-mismatched combinations. Recently, B-lymphocyte-associated antigens (HLA-DR or Ia-like) have been demonstrated on CFU-C[12,13]. The possibility that this antigen was the target of CFU-C inhibition was investigated by experiments in which an antiserum to human B-lymphocyte antisera failed to block CFU-C inhibition by sensitised PBMC[14] (control 114±6; sensitised culture 27±7; sensitised culture with anti-Ia, 21±3). The CFU-C inhibition observed between HLA-identical siblings is further indirect evidence that B-lymphocyte-associated antigens are not important in this

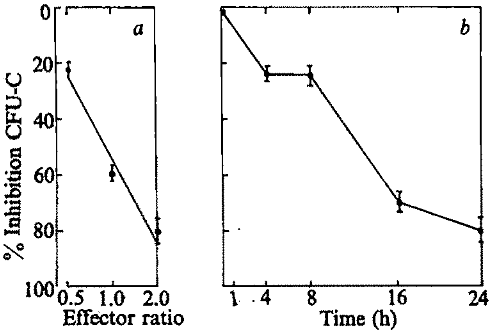

Fig. 3 Kinetics of CFU-C inhibition. Sensitised PBMC recovered from primary cultures were recultured with fresh bone marrow cells at various ratios (*a*) and for various lengths of time (*b*). The secondary cultures were then terminated and CFU-C assayed as indicated (Fig. 1).

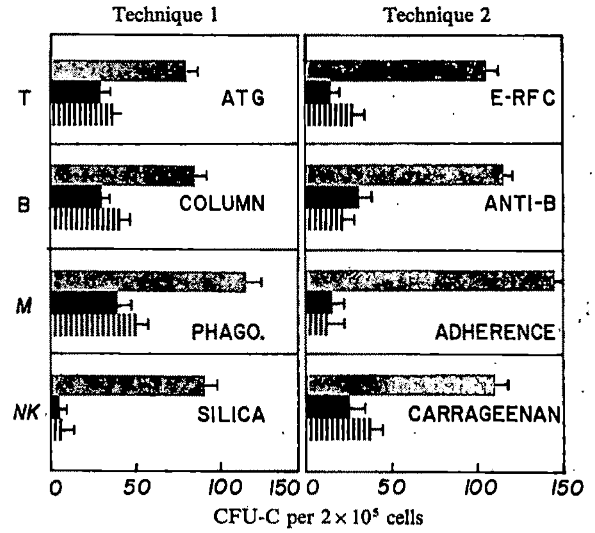

Fig. 4 Effects of cell fractionation on CFU-C inhibition in control cultures (stippled bars), sensitised cultures (black bars) and sensitised cultures depleted of selected mononuclear cell populations (striped bars) by the method indicated. Sensitised PBMC were fractionated using the procedures indicated. After each procedure the cells were washed, reconstituted to their original concentration and tested for CFU-C inhibition. Unfractionated sensitised PBMC served as a control. T-lymphocyte-depleted fractions were obtained by incubation of 10^7 PBMC (1.0 ml) with 0.25 ml equine anti-human thymocyte globulin (ATG; Upjohn–17912; $1:10^3$ dilution) and rabbit complement or by rosette formation with AET (2-aminoethylisothiouronium bromide hydrobromide) treated sheep erythrocytes (E-RFC) and centrifugation over a Ficoll–Hypaque density gradient[17]. T-depleted PBMC contained ≤5% E-rosette forming cells. B lymphotytes were depleted by adherence to nylon wool columns or by incubation with a rabbit anti-human B-lymphocyte antiserum and complement[18,19]. B-lymphocyte-depleted fractions contained ≤2% surface membrane Ig-positive ($SMIg^+$) cells. Monocyte–macrophage-depleted (M) fractions were obtained by incubation with carbonyl iron (lymphocyte separating reagent, Technicon) and passage through a laboratory magnet or by adherence to polystyrene surfces. Macrophage-depleted fractions contained ≤5% nonspecific esterase staining cells. NK cells were inactivated by incubation with silica or carrageenen. PBMC were incubated for 30 min with silica, 0.1–1.5 mg ml^{-1} (Sigma; particle size <0.4 μm). The silica was sonicated and used uncoated or after incubation with 10% FCS. PBMC were also incubated with carrageenen, 0.15 mg ml^{-1} (Hathaway Allied Products) for 60 min. Treated fractions were tested for NK activity against sensitive (K-562, MOLT-4) and resistant (RAJI) cell lines. In each instance NK activity was absent[20,21]. HLA-identical siblings were used in the experiments involving T lymphocytes. In other experiments HLA-mismatched, unrelated donors were used.

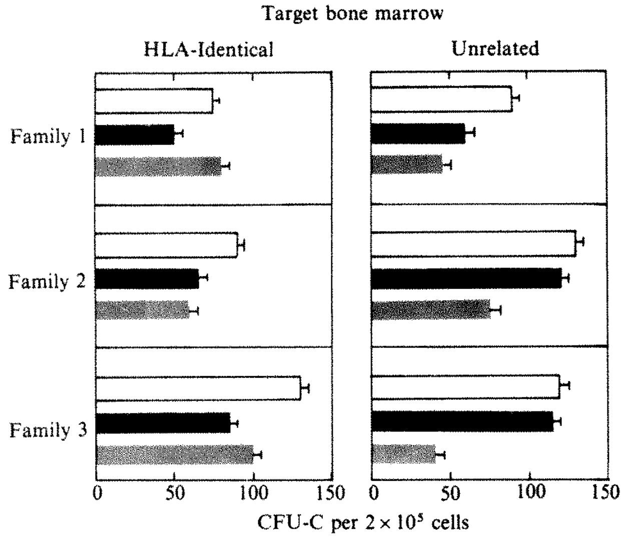

Fig. 5 CFU-C inhibition between HLA identical siblings. In three families with two HLA-identical siblings, PBMC from one sibling were sensitised against bone marrow cells from either the HLA-identical sibling (black bars) or an unrelated individual (stippled bars). Their sensitised PBMC were then tested for CFU-C inhibition by co-culture with fresh bone marrow from either the sibling (left panel) or the unrelated individual (right panel). The values indicated by the clear bars represents the number of CFU-C present when target bone marrow was cultured with PBMC sensitised against autologous bone marrow cells in primary culture.

system, as these antigens are closely linked or identical to the HLA-D locus shared by these siblings[15].

We have thus demonstrated that PBMC sensitised against allogeneic but not autologous bone marrow contain a population of cells which inhibit haematopoietic stem cells committed to granulocyte–macrophage differentiation (CFU-C). The effector cell is not a conventional T or B lymphocyte, monocyte-macrophage or NK cell. The target antigen(s) on the CFU-C is unknown but is not HLA or a B-lymphocyte-associated (HLA-DR or Ia-like) antigen. This system should prove useful for studying immunity to non-HLA antigens and as a model for bone marrow graft rejection in man.

Dr R. Billings provided the anti-human B-lymphocyte antisera, the ATG was from Dr A. Elberg (UpJohn), Dr M. Tagasuki assayed NK activity, Dr P. Terasaki carried out the HLA typing, Drs E. Arenson, A. Saxon and S. Targan collaborated in the cell fractionation experiments, and Drs M. Cline and D. Golde critically reviewed the manuscript. This work was supported by grants CA-23175, CA-12800 and CA-15688 from the NCI and RR-865 from the USPHS. R.P.G. is a Scholar of the Leukemia Society of America.

H-2 restriction of contact inhibition of epithelial cells

A. S. G. Curtis & Paul Rooney

Department of Cell Biology, University of Glasgow, Glasgow, UK

Medawar has suggested[1] that the major histocompatibility gene complex (MHC) might be involved in the contact inhibition of movement[2] shown by fibroblasts and epithelia. Contact inhibition of movement[3] is that reaction of cells which stops the movement of one cell over another and thus leads to monolayering and other features of morphology typical of cells in culture and *in vivo*[4]. By confronting epithelial outgrowths we have compared contact inhibition between syngeneic cells with that between allogeneic cells. Contact inhibition was more marked between allogeneic combinations than syngeneic combinations, when the genetic mismatch lay in certain parts of the MHC complex.

A number of cell interaction gene loci (CI loci) have been recognised in lymphocyte–lymphocyte and lymphocyte–macrophage interactions[5], controlling such reactions as T–B lymphocyte cooperation in antibody responses, and the T–T lymphocyte reactions in the genesis of cytotoxic lymphocytes (CTL)[6], as well as the reaction of the CTL with their target cell (which may be fibroblasts). These CI loci map in the MHC and, in mice, afford examples of H-2 restriction. If the CI loci actually control the interaction part of the process, rather than the response to the interaction, a question that has not been answered, we would already possess clear evidence that some cell interaction phenomena (rather than a consequent response) are under MHC control. There is evidence to show that cell adhesion of mouse fibroblasts is under H-2 control[7], that the adhesion of mouse lymphoid cells is under the control of one or more of the loci K, IA, IB, D or L (though minor effects of others could not be excluded)[8], that the adhesion of mouse T lymphocytes is controlled by loci D and/or L and perhaps IB, IC and IJ (ref. 9), and that mouse B lymphocyte adhesion is controlled by loci K and perhaps IB and IC (ref. 10). In refs 9 and 10, clear evidence was presented that allogeneic combinations of cells, mismatched at these loci, led to a diminution of adhesion, effected by soluble glycoproteins secreted by the cells.

Epithelia, which would be expected to show marked contact inhibition of movement[11], were grown as outgrowths of explants of adult mouse kidney tubule and the extent of contact inhibition measured (comparing the number of nuclear overlaps with the number expected on random grounds) in the area of confrontation between syngeneic or allogeneic outgrowths. The congeneic strains B10, B10.A, B10.A(2R), B10.A(4R), B10.AKM, B10.G, B10.BR and B10.HTT were used, and also strain ATL. The results are shown in Table 1.

The results show that although there is a low overlap index (marked contact inhibition of movement) in the syngeneic controls, the allogeneic combinations show a very low overlap index, significantly below that of the controls, when certain loci are mismatched between the two strain types in the culture. In other words, there is an H-2 restriction affecting the extent of contact inhibition. If the cells involved are mismatched at K or/and D, contact inhibition is markedly increased.

It might be expected that in a culture dish containing equal numbers of explants from two strain types, 50% of the confronted outgrowths would be syngeneic and 50% allogeneic, and thus, that a population of overlap indices with two (possibly three) different means corresponding to two syngeneic and one allogeneic groups. Yet, all confronted outgrowths in such cultures show a very low overlap index (see Table 1.). A simple

Data are from epithelial cultures grown as outgrowths from explants for 3 days in Hams F10 (modified with 0.02 M HEPES + 0.004 M $NaHCO_3$ *p*H7.4) and 10% fetal calf serum. Contact inhibition was measured as nuclear overlap index on areas of $7.08 \times 10^{-8} m^2$, 30 areas per culture type. $P = 0.01$ for $t = 2.66$, 58 d.f.

* Mean; s.d. in parentheses.

explanation of this effect would be that cells produce a soluble diffusible factor that affects the contact inhibition of cells allogeneic to the producer cells. Similar substances affecting cell adhesion have been described and characterised as glycoproteins from T and from B lymphocytes and have been shown to reduce the adhesion of allogeneic lymphocytes, if they are mismatched at H-2 D or L (T cells) or H-2 K (B cells)[9,10]. There is some evidence for Ia antigen involvement in adhesion[9,10]. It is likely that contact inhibition of movement is at least partially controlled by adhesion[3].

It is not yet clear how these soluble factors are received by the target cells. Interestingly, Snell[12], reviewing work on MHC receptors in T cells, points out that the I region may contain pairs of closely linked genes determining interacting cell surface structures. If any locus is involved in adhesion, the presence of allogeneic cells (or their factors) may lead to competitive inhibition of such sites and thus diminution of adhesion.

Bodmer[13] suggested that the true role of the MHC systems might be the control of cell–cell recognition. Normally, this recognition is, of course, predominantly a syngeneic phenomenon. The results we describe suggest that contact inhibition of movement, long believed to be involved in organogenesis, is under MHC control. Extreme contact inhibition seen in certain allogeneic combinations would prevent the interdigitation of cells required for the normal formation of tissues such as epithelia, and might, by itself, prevent proper fusion of allogeneic grafts. The problem yet to be solved is how syngeneic tissues within one organism differ sufficiently to separate and position themselves differently: one suggestion is that the display of MHC antigens varies between different tissues in such a way that pairs of cell types, one lacking and the other showing the expression of a certain locus, will interact in a different manner from those sharing its expression.

Mechanical activation and voltage-dependent charge movement in stretched muscle fibres

Chiu Shuen Hui* & W. F. Gilly†

Department of Physiology, Yale University Medical School,
New Haven, Connecticut 06510

Although properties of the intramembranous charge movement in frog skeletal muscle have now been fairly well characterised[1–5], the function of this process remains uncertain[6–9]. Schneider and Chandler[1] first suggested that the observed charge movement in sartorius fibres held near slack length in a hypertonic paralysing solution took place within the transverse (T) tubular membranes in the region of the triad feet and signalled tubular depolarisation to the sarcoplasmic reticulum (SR), thereby initiating calcium release. More recently it has been reported that much of this charge movement is abolished in semitendinosus fibres stretched well beyond slack length in hypertonic Ringer solution[10]. Other studies using intracellular calcium indicators, however, have shown that substantial amounts of calcium are released by brief depolarisations in muscle fibres stretched to sarcomere lengths of 4.0 μm or more, when bathed in isotonic solutions[11–13]. The question thus arises, is charge movement abolished in muscle fibres stretched in an isotonic Ringer solution? As calcium release persists in these conditions, an inhibition of charge movement would make involvement of this phenomenon with calcium release very unlikely. We report here the influence of stretch on charge movement and on an aspect of mechanical activation indicative of calcium release using standard, microelectrode voltage-clamp experiments on intact frog twitch fibres. We found no dramatic dependence of these properties on fibre length, and the possibility of a functional role for charge movement in the regulation of calcium release remains.

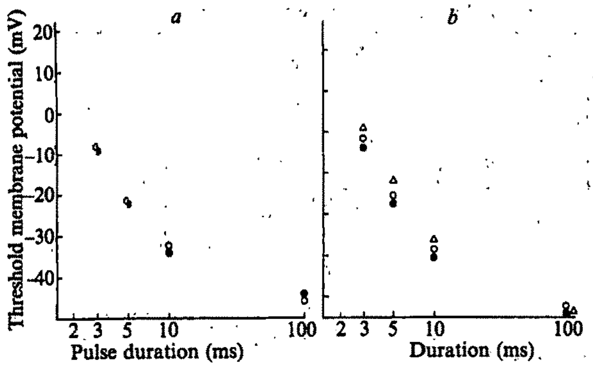

Fig. 1 Strength–duration curves for threshold mechanical responses in voltage-clamped twitch fibres at different sarcomere lengths. Membrane potential at threshold is plotted against duration of the depolarising voltage clamp pulse. Holding potential, −80 mV; temperature, 9–10 °C throughout. *a*, *Rana temporaria* sartorius muscle. Sarcomere lengths: ○, 2.5–2.78 μm; ●, 2.0–2.42 μm, mean values for eight fibres. *b*, *Rana pipiens*. ●, mean values from six sartorius fibres 2.27–2.50 μm long ○, △: Means from six semitendinosus fibres at 2.97–3.07 μm (○) and 3.33–3.48 μm (△) (data obtained by L. L. Costantin on isolated, single fibres).

Threshold mechanical responses to relatively brief (<100 ms) depolarisations in a voltage-clamped muscle fibre are a functional, although indirect, indication of the voltage dependence of calcium release[6,14–16]. The method has been described in detail elsewhere[5,15]. A muscle fibre was visualised under a water immersion objective and impaled with two microelectrodes to measure the intracellular voltage and to pass current through a voltage clamp feedback loop. Sarcomere shortening in response to depolarising voltage clamp pulses of various durations was observed at the surface of the muscle fibre, and the membrane potential at which shortening was just detectable is defined as threshold. Mechanical threshold increases with decreasing pulse duration, so that a brief pulse must be much larger than a long one to bring the myoplasmic calcium level up to threshold.

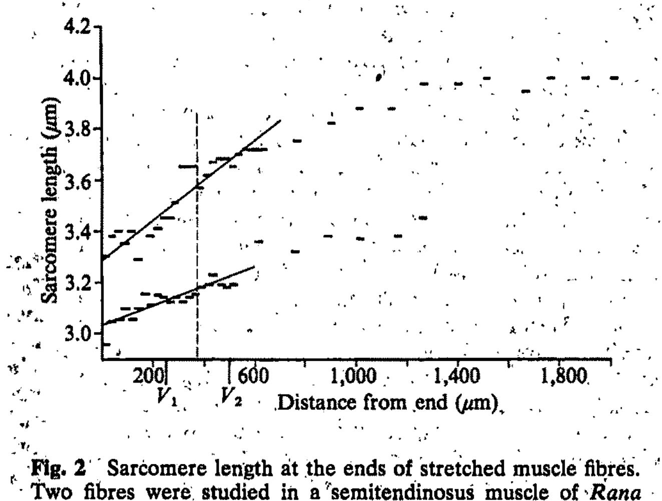

Fig. 2 Sarcomere length at the ends of stretched muscle fibres. Two fibres were studied in a semitendinosus muscle of *Rana pipiens* mounted exactly in the same way as for an electrophysiological experiment. The distance spanned by 10 sarcomeres was measured with a ×10 Filar micrometer (×40 water immersion objective) and divided by 10 to yield sarcomere length. This value is plotted as a bar over the length of measurement. V_1 and V_2 indicate positions of the intracellular voltage sensing micro-electrodes for charge movement experiments; current was sampled over the terminal 375 μm (vertical dotted line). Solid lines drawn by eye.

Figure 1*a* shows strength–duration (*S–D*) curves for threshold contractions in sartorius fibres from *Rana temporaria* at 9 °C. Means from two populations of fibres at different sarcomere lengths (2.0–2.4 μm and 2.5–2.8 μm) are shown. Long pulse thresholds represent a steady state balance between release and re-uptake of calcium by the SR, while short pulse

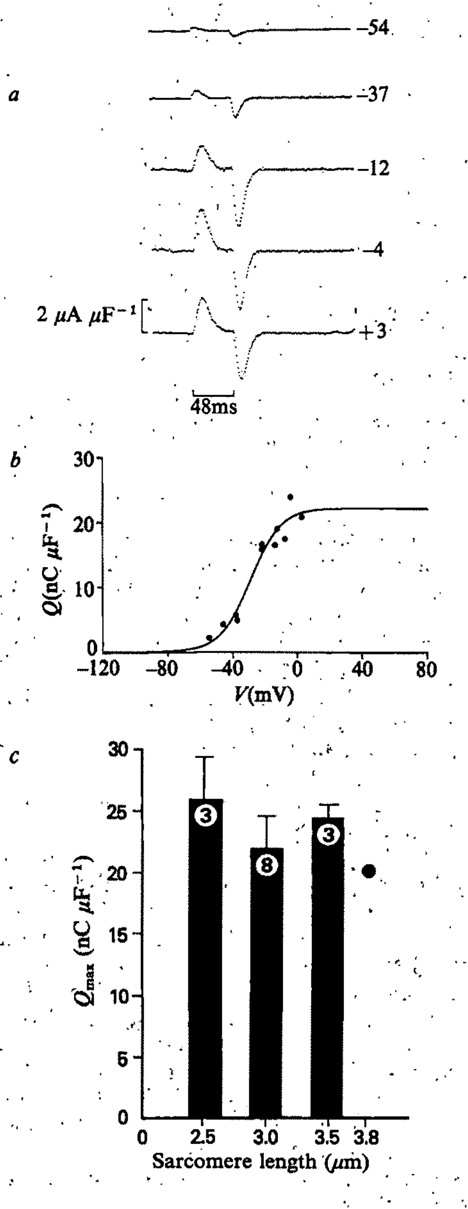

Fig. 3 Charge movement in stretched twitch fibres. *a*, Membrane current ($\Delta V = V_1 - V_2$) for depolarisation to the voltages, in mV, as indicated. Bathing solution contained 115 mM TEA-Cl, 2.5 mM KCl, 11.8 mM $CaCl_2$, 1 mM PIPES, and 2 mM tetracaine. Electrodes spaced 250 μm apart (see Fig. 2); R_i assumed to be 255.2 Ω cm: 1 μA μF⁻¹ corresponds to 1.3 mV of ΔV. Fibre OCT23-78-F4; sarcomere length, 3.0 μm; 7 °C; holding potential −80 mV; feedback control taken from V_2. Uppermost trace is the average of eight sweeps; others are averages of four sweeps. See refs 2, 5 for details of measurement. *b*, Steady state *Q–V* plot for the fibre in (*a*). The points were obtained from the time integrals of current traces, some of which are shown in (*a*). The smooth curve was drawn according to the equation[1]

$$Q(V) = Q_{\max}\left[1+\exp\left(-\frac{V-\bar{V}}{k}\right)\right]^{-1}$$

and was fitted to the points by least squares. The best fit parameters were $\bar{V} = -28.6$ mV, $k = 9.3$ mV, $Q_{\max} = 22.1$ nC μF⁻¹. *c*, Maximum moveable, nonlinear charge, $Q_{\max}$, as a function of sarcomere length at the V_1 electrode. error bars indicate one standard deviation; number of fibres is indicated. Point at 3.8 μm is from one measurement at +5 mV.

thresholds (<10 ms) are probably set by the voltage-dependent kinetics of some regulatory step preceding calcium release. Values at all durations are indistinguishable in these two groups of fibres, suggesting no functional impairment of calcium release by this amount of stretch.

A somewhat greater length range was investigated in *Rana pipiens* sartorius and semitendinosus (single) fibres (Fig. 1*b*). Data from single fibres were obtained by the late Dr L. L. Costantin and have been tabulated previously[15]. Only the means for 2 ms of the 2.27–2.50 and 3.33–3.48 μm populations are significantly different at the 95% level by *t*-test. Again, a major influence of stretch on calcium release is not apparent.

To study membrane charge movements in intact fibres it is necessary to abolish contraction in response to depolarisation. We used an isotonic paralysing solution containing 2 mM tetracaine. Almers and Best[6] have shown that this drug does not interfere with charge movement, and probably directly inhibits the calcium release process in the SR membranes. The solution also contained 115 mM tetraethylammonium (TEA) chloride and 5 mM RbCl to block K currents, tetrodotoxin to block Na currents, 11.8 mM $CaCl_2$ to minimise leakage conductance around the electrodes, and 1 mM PIPES buffer (*p*H 7.0). Temperature was 7 °C.

The three electrode voltage-clamp technique used allows an approximate measurement of membrane current density at the end of a muscle fibre[17]. Feedback control was taken from the electrode more distant (500 μm) from the fibre end (V_2), and the current trace was integrated to determine capacitance as described by Schneider and Chandler[18]. Pulse duration was 48 ms; control pulses were obtained over the range of −80 to −150 mV (refs 1, 2). Membrane current amplitude and the quantity of charge were normalised by the effective membrane capacitance, to be in units of $\mu A\ \mu F^{-1}$ and $nC\ \mu F^{-1}$, respectively. This removes the dependence of charge movement measurements on fibre radius, internal resistivity (R_i), and inter-electrode spacing.

Inhomogeneity of sarcomere spacing at the fibre's end[19] adds a complication to these experiments, however. As current is effectively sampled over the last several hundred micrometres of fibre length, a large number of short sarcomeres at the very end might mask any effect of stretch. To check this, sarcomere spacing was measured at the ends of two semitendinosus fibres in a bundle pinned out in the same manner as for a voltage-clamp experiment. Results are shown in Fig. 2. In both cases a substantial difference in sarcomere length does exist between the end and the middle of the fibre. Over the region in which current was measured in these experiments (the terminal 375 μm), however, there is only a 5–10% decrease in sarcomere length. Charge movement measurements are referred to the sarcomere length measured at the V_1 electrode, 250 μm from the fibre end. It is not likely that an inhomogeneity of sarcomere spacing in this region seriously affects our results.

Figure 3*a* shows examples of charge movement traces at several voltages from a semitendinosus twitch fibre stretched to 3.0 μm sarcomere length. The magnitude of the charge movement increases and the kinetics become faster as the pulses get larger. Figure 3*b* shows the amount of charge moved during each pulse. The solid curve is drawn according to the usual Boltzmann distribution model[1] with a steepness of *e*-fold for 9 mV and a saturating Q_{max} value of 22 $nC\ \mu F^{-1}$. The shape of this Q–V curve is very similar to that obtained from fibres at rather shorter lengths in both isotonic[6] and hypertonic[2,3] solutions, although hypertonicity appears to shift the curve 15–20 mV in the negative direction[6].

Figure 3*c* summarises results from semitendinosus twitch fibres at different degrees of stretch. The total amount of moveable charge, Q_{max}, does not significantly depend on sarcomere length. The point at 3.8 μm is for a single pulse to +5 mV, immediately after which the fibre broke.

While Q_{max} and the steepness of the Q–V distribution do not appear to depend greatly on stretch (see also ref. 20), these are steady state properties, and it remains possible that stretch does slow the kinetics of charge movement. This could be due to a real effect of stretch on the process generating the charge movement or to an indirect effect on some cable properties of the muscle fibre. The records in Fig. 3*a* are not obviously slower than other published records; additional experiments are required to study more carefully the effect of stretch on charge movement kinetics. Any effect of stretch on kinetics might also be augmented in a hypertonic Ringer solution.

Neither the properties of charge movement nor of mechanical activation we measured in fibres in isotonic solutions are significantly affected by stretch to sarcomere lengths at which the contractile filaments no longer overlap. These observations are consistent with the possibility that charge movement in skeletal muscle has a role in regulating calcium release.

We thank Dr S. M. Baylor for discussions and the 3.8-μm fibre. This work was supported by a grant from the NIH to Dr W. K. Chandler.

Renal brush border membrane adaptation to phosphorus deprivation in the *Hyp*/Y mouse

H. S. Tenenhouse & C. R. Scriver

Medical Research Council Genetics Group, Human Genetics Center, (McGill University) and De Belle Laboratory for Biochemical Genetics, McGill University-Montreal Children's Hospital, Research Institute, 2300 Tupper Street, Montreal, Quebec, Canada H3H 1P3

Human X-linked hypophosphataemia (XLH)[1] involves a partial loss in net renal reabsorption of phosphate anion (P_i). The mutant male hemizygote has about half the normal renal transport activity[2] and this is quite insensitive to circulating parathyroid hormone (PTH)[2,3]. The renal defect is sufficient to explain persistent hypophosphataemia in XLH. The hypophosphataemic mouse (*Hyp*)[4] also has an X-linked defect in renal reabsorption of P_i (refs 4–7). The mutant male hemizygote (*Hyp*/Y) has about half the normal renal reabsorption activity and this abnormality persists after parathyroidectomy[7]. Conservation of the X chromosome during mammalian evolution and evidence for functional homology between species for specific X-linked genes[8] have encouraged us to use the *Hyp* mouse as a model for the renal defect in XLH. We have studied P_i transport in purified renal brush border membrane vesicles (BBMV) prepared from *Hyp*/Y mice[5,9]. A selective loss involving almost half the Na^+-dependent P_i co-transport activity is

0028–0836/79/380225—03$01.00

present in *Hyp*/Y membranes. These findings, genetic studies in man[2,10] and recent physiological evidence[11] suggest that P_i transport in the mammalian nephron occurs by at least two processes: one under the control of an X-linked gene that is more sensitive to PTH inhibition and another process, controlled by an autosomal locus, that is less sensitive to the hormone. We report here on the ability of the *Hyp*/Y mouse to adapt to phosphorus deprivation; the response is observed both *in vivo* in net reabsorption of P_i and *in vitro* in BBMV transport of P_i.

Hyp mice were bred and reared in our laboratory. Adult (>100 d old) *Hyp*/Y and normal +/Y littermates were given either a control diet containing 0.4% (w/w) phosphorus or a low-P diet containing 0.03% phosphorus. Both diets contained the same amount of calcium (0.4% w/w). The animals were not thyroparathyroidectomised. After 2 weeks, mice were placed in Gelman metabolic cages; blood and urine was collected and analysed for calcium, phosphorus and creatinine content measured as before[5].

Table 1 shows that in both *Hyp*/Y and +/Y mice there was *in vivo* renal adaptation to phosphorus deprivation, whereas calcium excretion increased, as expected[12]. Renal adaptation did not fully correct the mutant phenotype: *Hyp*/Y animals, in the adapted state, maintained lower ($P < 0.001$) plasma levels and a higher ($P < 0.001$) fractional excretion of phosphorus than +/Y mice in the adapted state.

Purified BBMV were prepared from *Hyp*/Y and +/Y renal cortex by the method of Booth and Kenny[13] and incubated as before[5,9]. Net uptake of $^{32}P_i$ (100 μM) by BBMV was measured after 15 or 30 s incubation in the presence of NaCl or KCl gradients. The simultaneous uptake of D-glucose (20 μM) was also measured and Na^+/glucose co-transport was used as an internal control. D-glucose and P_i at their respective concentrations did not interfere with the co-transport of each other, and the possibility of significant binding of phosphate to BBMV was excluded by the appropriate osmotic experiments in a sucrose medium[9].

P_i transport activity, both absolute and normalised to simultaneous D-glucose uptake, was significantly greater ($P < 0.001$) in BBMV prepared from *Hyp*/Y and +/Y mice adapted to phosphorus deprivation than in BBMV prepared from animals fed the control diet (Table 2). The characteristic deficiency of Na^+/P_i co-transport activity in *Hyp*/Y membranes was retained in the adapted state. We also examined the kinetics of P_i uptake by adapted BBMV, and found that although there was no change in the apparent K_m value, the V_{max} for uptake was increased twofold in the adapted state (Fig. 1).

These findings are of interest for the interpretation of *in vivo* adaptation to phosphorus deprivation, a phenomenon reported earlier for rat[14] and dog[15]. Others have observed that the adapted kidney becomes insensitive to PTH[16], that adaptation is not dependent on the integrity of parathyroid or thyroid glands[17,18] and that, depending on the species, days or weeks are required for the phenomenon to appear[15,18]. The adaptation is a function of the early proximal renal tubule although more distal parts may also be involved[12,19]. Our findings indicate that renal

Table 1 *In vivo* renal adaptation to chronic phosphorus deprivation in +/Y and *Hyp*/Y littermates (mean ± s.e.)

	+/Y mice		*Hyp*/Y mice	
	Control diet ($n = 4$)	Low-P diet ($n = 4$)	Control diet ($n = 4$)	Low-P diet ($n = 4$)
Plasma P_i (mg dl^{-1})	8.33 ± 0.62	5.09 ± 0.84*	3.97 ± 0.19†	1.01 ± 0.14*†
Phosphorus excretion index	0.280 ± 0.021	0.005 ± 0.001*	0.569 ± 0.024†	0.034 ± 0.004*†
Calcium excretion index	0.015 ± 0.0002	0.175 ± 0.003*	0.016 ± 0.0003	0.192 ± 0.004*

Littermate animals were classified as +/Y (normal male) and *Hyp*/Y (mutant hemizygote) according to quantitative and qualitative phenotypic features[4]. Adult mice were given specified diets (ICN) for 2 weeks. Urine was collected for about 3 h, after which blood was obtained from the tail. Samples were analysed as described elsewhere[5]. Total phosphorus content of diets: control, 0.4% (w/w); Low-P, 0.03% determined by chemical analysis according to Trohler *et al.*[17]. Excretion index (analogous to fractional excretion) is derived from the equation: (urine [P_i] or [Ca] × plasma [creatinine])/(plasma [P_i] or [Ca] × urine [creatinine]).

*Different from control-diet animals: $P < 0.001$, Student *t*-test.

†Different from +/Y animals on corresponding diet: $P < 0.001$, Student *t*-test.

Table 2 Uptake of ^{32}P and ^{14}C-D-glucose by renal brush border membrane vesicles from adult control (+/Y) and hypophosphataemic (*Hyp*/Y) male mice

	+/Y		*Hyp*/Y	
	Control diet (0.4%P)	Low-P diet (0.03%P)	Control diet (0.4%P)	Low-P diet (0.03%P)
P_i uptake (30 s) (pmol per mg protein)				
In KCl	81.4 ± 7.4	67.8 ± 8.9	60.7 ± 8.6	55.7 ± 3.8
In NaCl	807.8 ± 55.8	1,596.2 ± 84.7*	617.4 ± 31.6†	902.5 ± 82.3†*
Normalised P_i uptake (30 s; Na dependent) (pmol P per pmol D-glucose)	9.0 ± 0.2	25.2 ± 1.4*	3.6 ± 0.2†	14.5 ± 0.7†*

Net uptake of ^{32}P-labelled orthophosphate (100 μM) was measured at 30 s by BBMV prepared from renal cortex of normal male (+/Y) and hemizygous (*Hyp*/Y) littermates. The membranes were isolated and purified by the method Booth and Kenny[13], and suspended in 300 mM mannitol and 20 mM Tris-HEPES, *p*H 7.4, at a final protein concentration of 2–3 mg ml^{-1}. Uptake was measured by the Millipore technique used previously[5,9]. The reaction was initiated by adding 90 μl of incubation medium containing ^{32}P and ^{14}C-D-glucose (20 μM) to 10 μl of brush border membrane preparation at 20°C. The reaction was terminated by the addition of 4 ml stop solution (100 mM mannitol, 100 mM NaCl, 20 mM Tris-HEPES and 10 mM arsenate *p*H 7.4, 4°C), and filtered immediately through a 0.45-μm Millipore filter. After two rapid additional washes with stop solution the filters were counted in Aquasol-2 in a liquid scintillation counter. Incubation solutions were: (1) 100 mM KCl, 100 mM mannitol and 20 mM Tris-HEPES, *p*H 7.4; (2) 100 mM NaCl, 100 mM mannitol and 20 mM Tris-HEPES, *p*H 7.4. Background counts were subtracted from experimental counts; the former were always less than 15% of uptake at equilibrium in the presence of membranes. Phosphate is not significantly bound to BBMV and is entirely retained as the inorganic anion after uptake[5,9].

*Difference between low P and control diet is significant: $P < 0.001$, Student *t*-test.

†Difference between +/Y and *Hyp*/Y is significant: $P < 0.001$, Student *t*-test. Data are mean ± s.e.m. of five determinations.

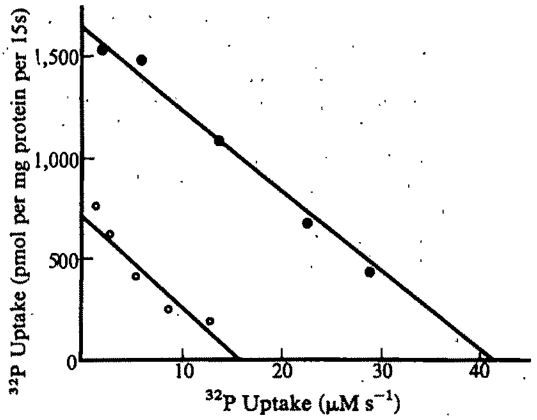

Fig. 1 Eadie–Hofstee plots of the Na$^+$-dependent uptake of ^{32}P at 15 s by BBMV prepared from kidneys of adult normal mice fed control diet (0.4%, w/w) (○) and low-P diet (0.03%) (●), each for 2 weeks. The apparent K_m values are 45 μM in mice fed the control diet and 40 μM in P-deprived mice; V_{max} is increased in the adapted animal (1,659 pmol per mg protein per 15 s compared with 722 pmol per mg protein per 15 s ($P<0.001$)). The correlation coefficients for the regressions were 0.886 and 0.850 for control and P-deprived animals, respectively, over the concentration range 15–800 μM P_i. See Table 2 for details of BBMV incubation and transport assay. Kinetic values refer to Na-dependent uptake exclusively, that is, total uptake in NaCl minus diffusional uptake in KCl.

adaptation to phosphorus deprivation *in vivo* involves a change in P_i transport activity in the brush border membrane. This adaptation occurs in the presence of parathyroid hormone *in vivo* and seems to involve a selective change in the number or activity of carriers specific for phosphate anion. Because adaptation occurs in the *Hyp*/Y animal, we suggest that a brush border membrane mechanism for P_i transport, other than that controlled by the X-linked gene, is responsible for the enhanced BBMV P_i transport activity. The signal for this adaptation is unknown: the hypophosphataemic *Hyp*/Y phenotype itself is insufficient to produce this, and the additional stimulus of environmental phosphorus deprivation is required to evince the membrane responsible in the *Hyp* animal. It is interesting that renal phosphorus content in *Hyp* mice does not differ from normal[5]. We have also observed that phosphorus levels in renal cortex are similar in control and adapted mice[20].

Is adenosine the mediator of opiate action on neuronal firing rate?

Trevor W. Stone & Martin N. Perkins

Department of Physiology, St. George's Hospital Medical School, University of London, London SW1, UK

Despite recent advances[1,2], relatively little is known of the mechanism of action of opiate analgesics at the cellular level. There is evidence, however, that the inhibition of neurotransmitter release produced by morphine may be mediated by the initial release of adenosine[3–5]; the effect is mimicked by adenosine and the actions of both adenosine and morphine are blocked by theophylline and enhanced by dipyridamole[3–5]. When applied microiontophoretically, adenosine has also been shown to be a potent depressant of the firing rate of single neurones in the mammalian brain, and a similar depressant effect of morphine has been claimed to be stereospecific, antagonised by naloxone[6–9] and greatly reduced in animals made tolerant to, and dependent on, morphine[8,9]. The experiments described here examine the effect of aminophylline, a soluble theophylline derivative, on these depressant effects. We have found that aminophylline will block responses to both morphine and adenosine, suggesting that the depressant responses to morphine may also be mediated by the local release of adenosine.

Male Porton Wistar rats were anaesthetised with urethane, 1.3 g per kg, intraperitoneally. The animals were placed in a stereotaxic frame and the body temperature automatically maintained at 37–38 °C. A burr hole was made so as to allow electrode penetration into the corpus striatum at coordinates according to the atlas of DeGroot[10].

Drugs were applied by microiontophoresis from six- or seven-barrelled micropipettes of tip diameters 4–12 μm. The drugs used were: morphine sulphate, 50 or 100 mM, *p*H 5.5; adenosine hemisulphate, 100 mM, *p*H 4; γ-aminobutyric acid (GABA), 100 mM, *p*H 4; naloxone HCl 50 mM, *p*H 5; aminophylline (theophylline ethylenediamine), 50 mM, *p*H 9 (unadjusted). The latter drug was injected as an anion, and the rest as cations. No retaining current was applied to aminophylline. One barrel of the micropipette contained 165 mM NaCl for current balancing and testing. Action potentials were recorded through another barrel of the multibarrel pipette, filled with 3 M NaCl, or through a separate, single microelectrode glued alongside the multibarrel[11]. The spikes were amplified, gated and displayed on oscilloscopes and the gated pulses were counted and displayed on a polygraph as a record of spikes per s.

The effect of local application of morphine was studied in 127 neurones in the rat striatum using currents of 60–160 nA. Of these, 72 were found to be depressed, 23 excited and 32 did not respond to the alkaloid. The firing of most of the inhibited units was suppressed completely within 1–2 s and recovery from this depression was also rapid, the original firing rate returning within 5–10 s of terminating the ejection current (Fig. 1). On 20 quiescent cells morphine and adenosine also reduced the excitation induced by iontophoretically applied glutamate. The time course of the depression was similar to that of spontaneously firing units.

Adenosine and GABA also depressed neurones responding to morphine (Fig. 1) when applied with currents ranging from 45 to 120 nA. Again, the onset and recovery from these inhibitions were rapid, as has been described previously[12].

The opiate antagonist naloxone was then applied to 29 cells in an attempt to block the responses to morphine. Typically, both inhibitory and excitatory responses were difficult to antagonise, a problem exacerbated by the direct depressant effect of naloxone itself. However, 14 cells did show a reduction of morphine responses whereas GABA responses were unaffected, although recovery from naloxone blockade was slow.

The effects of aminophylline on morphine responses has been tested on 15 neurones. Nine of these exhibited some increase of

0028–0836/79/380227—02$01.00

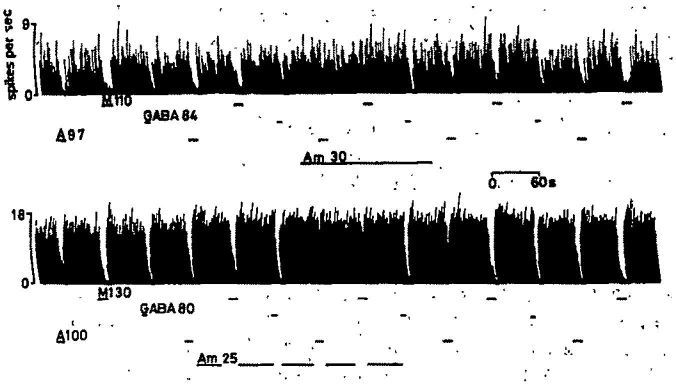

Fig. 1 Ratemeter records of the firing rate of two spontaneously active neurones in the rat striatum. The firing of both cells was depressed by the application by microiontophoresis of adenosine (A), morphine (M) and GABA. The application of aminophylline (Am) as an anion rapidly blocked the responses to adenosine and morphine, whereas GABA responses were unaffected. The times of drug application are shown by bars below the records, and the figures are the iontophoretic currents used, in nA. Time bar, 60 s.

baseline firing rate during the ejection of aminophylline. In all 15 cells the depressant responses to morphine were rapidly and reversibly antagonised by doses of aminophylline ranging from 14 to 90 nA, and an example of this is shown in Fig. 1. Depressant responses to adenosine were always greatly reduced or abolished in parallel with the loss of morphine responses, whereas the effects of GABA remained unaffected (Fig. 1). Ethylenediamine had no effect on the agonist responses.

These experiments demonstrate a powerful depression by morphine of the firing rate of neurones in the rat corpus striatum, an area which was chosen for this study because it contains a high density of opiate receptors[13,14]. The ability of naloxone to antagonise the morphine depression of firing supports the view expressed by others that such depressant responses result from an action on the specific opiate receptor[6–9], although the difficulty experienced with naloxone may result from an action of morphine on several classes of receptor, as discussed by Lord *et al.*[15].

The inhibitory effect of iontophoretically applied adenosine has been previously described as a widespread phenomenon in the central nervous system[12,16–19]. Furthermore, the effects of this purine in many tissues and preparations can be blocked by methylxanthine derivatives such as theophylline[3–6,12,16–22]. Our demonstration that aminophylline can antagonise responses to both adenosine and morphine but not GABA, while the effects of morphine, but not adenosine, can be blocked by naloxone leads us to propose that the first result of the interaction of morphine with its receptor is a release of adenosine from the tissue. Such a sequence presumably also explained the inhibition of transmitter release by morphine and its modulation by dipyridamole and theophylline reported by other workers using peripheral[3,4] or central[5] models of transmitter release. Indeed, Fredholm and Vernet[23] have now shown directly that morphine will enhance the depolarisation-induced release of adenosine from neurones[23].

It could be argued that, as adenosine and morphine are potent inhibitors of calcium-dependent neurotransmitter release, such an action could contribute to their depressant effects on neuronal firing. Aminophylline might then reduce that action by increasing calcium availability in the presynaptic terminals. However, the only relevant work seems to be that of Edstrom and Phillis[24], who reported that adenosine hyperpolarised cortical neurones without affecting membrane conductance, although this finding, as the authors noted, does not prove a presynaptic site of action. On the other hand, we have demonstrated that the depressant effects of morphine and adenosine occur against excitatory responses to glutamate, an amino acid thought to act postsynaptically by increasing sodium conductance[25].

We also suggest that the release of adenosine may be highly relevant to the analgesic effects of morphine in the conscious animal, as morphine analgesia has been shown to be reduced by the systemic administration of theophylline[26]. Furthermore, Horrobin has claimed that adenosine is a potent antagonist of many of the effects of prostaglandins[27,28]. A release of adenosine by opiates as suggested here may therefore explain the antagonism by morphine of prostaglandin-induced increases in cyclic AMP[29,30], an action which Collier has proposed to be central to an understanding of opiate tolerance and dependence[31].

† Physiological Laboratories, Cambridge, UK

Nerve cells can maintain a very low intracellular calcium concentration ($[Ca^{2+}]_i$) against large Ca^{2+} electrochemical gradients (see ref. 1 for review). The properties of the calcium efflux from these cells depend on $[Ca^{2+}]_i$ (ref. 2), and within the physiological range, most Ca efflux depends on ATP (which stimulates with high affinity) and is insensitive to Na_i, Na_o and Ca_o (uncoupled Ca efflux). When the $[Ca^{2+}]_i$ is well above the physiological range, Ca efflux becomes only partially dependent on ATP (acting now with low affinity), is inhibited by Na_i and is stimulated by Na_o and Ca_o (Na–Ca exchange). Orthovanadate, a powerful inhibitor of the $(Na^+ + K^+)$ATPase and the Na pump[3,4], also inhibits the Ca-stimulated ATPase activity, which is the enzymatic basis for the uncoupled Ca pump, in human red cells[5]. The experiments reported here show that in squid axons the ATP-dependent uncoupled Ca efflux can be fully and reversibly inhibited by vanadate, whereas concentrations of vanadate 10 times higher have no effect on the Na–Ca exchange. This is another indication that the uncoupled Ca efflux represents an ATP-driven Ca pump, and supports the suggestion that the uncoupled Ca efflux and Na–Ca exchange are mediated by different mechanisms[2].

0028–0836/79/380228—02$01.00

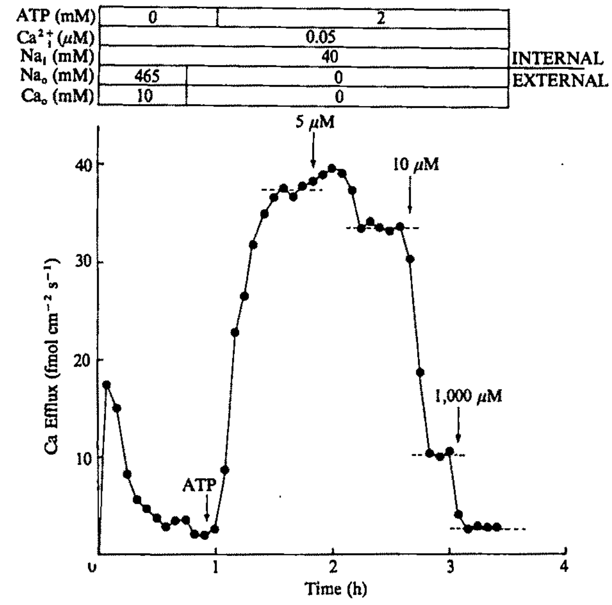

Fig. 1 Effect of different internal vanadate concentrations on Ca efflux in an axon dialysed with 0.05 μM $[Ca^{2+}]_i$ (axon 150379, 400 μM). The composition of the dialysis solution was (mM): K^+, 310; Na^+, 35; Mg^{2+}, 4 in excess to the ATP concentration; $Tris^+$, 5; Cl^-, 79; aspartate, 310; EGTA, 1; glycine, 330; and oligomycin, 10 μg ml^{-1}; at 980 mosmol, *p*H 7.1 (17 °C). ATP (Boehringer) and phosphoarginine (PA) (Calbiochem) were used as sodium salts and were stored at −90 °C as stock 250 mM solutions at *p*H 7.1 adjusted with Tris-OH (ATP) and HCl (PA). The ATP solution also contained 250 mM $MgCl_2$. The composition of the standard artificial seawater was (mM): Na^+, 465; K^+, 10; Mg^{2+}, 50; Ca^{2+}, 10; $Tris^+$, 10; Cl^-, 580; EDTA, 0.1; 1,000 mosmol, *p*H 7.6 (17 °C). Tris was used as a substitute for Na. Removal of Na_0 and Ca_0 was carried out without changing the other constituents. The nominally Ca-free seawater also contained 0.5 mM EGTA and no added Ca. The axon was incubated for 1 h before dialysis in artificial seawater containing 1 mM KCN. The arrows refer to addition of vanadate and the concentration is indicated. The flow of the dialysis solution was 1 μl min^{-1}. The flow of external solutions was about 1 ml min^{-1} and was collected at 5-min intervals, added to 5 ml of scintillator and counted. For more details of the dialysis technique see ref. 6.

The experiments were carried out on giant axons taken from live specimens of the tropical squid *Dorytheutis plei.* The intracellular concentration of low molecular weight solutes was controlled using the internal dialysis technique[6]. To inhibit endogenous ATP production, the axons were soaked in seawater containing 1 mM KCN for 1 h before the dialysis began. The production of ADP from the hydrolysis of exogenous ATP was minimised by adding 5 mM phosphoarginine to the dialysis solutions.

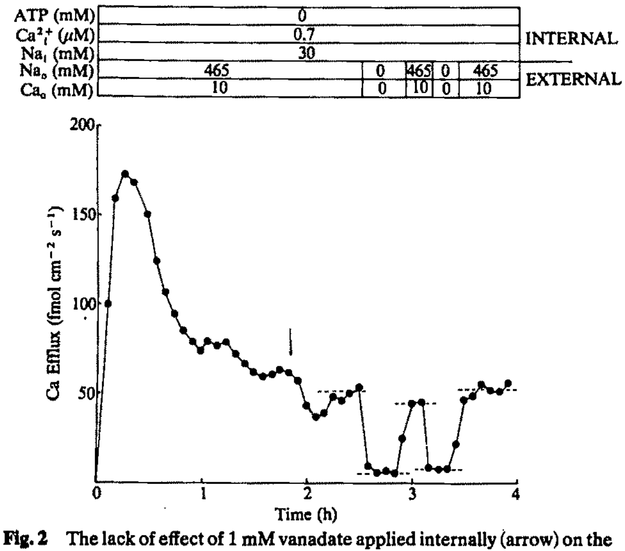

Fig. 2 The lack of effect of 1 mM vanadate applied internally (arrow) on the Na–Ca exchange in squid giant axon (axon 190179 B, 450 μm). In this experiment the axon was dialysed with a solution lacking ATP (to inhibit the uncoupled Ca efflux) and with 0.7 μM $[Ca^{2+}]_i$ to maximise the Na–Ca exchange component. The general technique was the same as that described in Fig. 1 legend.

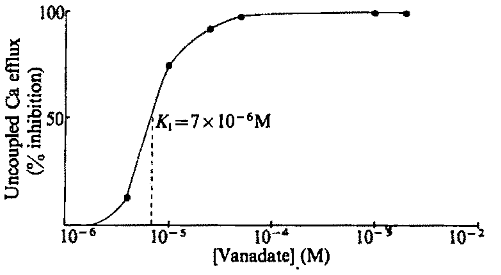

Fig. 3 Dose-response curve for the vanadate inhibition of the ATP-dependent 'uncoupled' Ca efflux in squid giant axons. The general technique was similar to that in Fig. 1, where after a steady Ca efflux was obtained in the presence of ATP, different concentrations of vanadate were tested. In all cases the external solutions lacked both Na and Ca. Each point is the mean of three axons. The inhibitory effect of vanadate was always reversible. ATP, 2 mM; Na_i, 40 mM; K_0, 10 mM; 17 °C.

Figure 1 shows that in an axon dialysed with 0.05 μM Ca^{2+} the ATP-dependent 'uncoupled' Ca efflux is progressively inhibited by increasing amounts of vanadate applied internally. The lack of effect of vanadate on the Na–Ca exchange is readily demonstrated in the experiment shown in Fig. 2. In this case the axon was dialysed with a solution free of ATP and containing 0.7 μM Ca^{2+} to maximise the Na–Ca exchange[2]. The addition of 1 mM vanadate did not significantly change the levels of Ca efflux. (The small reduction seen could be due to inhibition of an uncoupled Ca efflux caused by ATP remaining inside the axon.) In addition, the removal of Ca_0 and Na_0 reversibly inhibited Ca efflux, bringing it to leakage levels. Both the absolute magnitude of the Na_0–Ca_0-activated Ca efflux and the leakage levels are similar to those found in axons not poisoned with vanadate, dialysed with the same $[Ca^{2+}]_i$. Results similar to those shown in Figs 1 and 2 were seen in three other experiments. Figure 3 is a dose-response curve for the vanadate inhibition of the ATP-dependent uncoupled Ca efflux in axons dialysed with 0.05 μM Ca^{2+}. From the curve, the K_i for vanadate is about 7×10^{-6} M. The inhibition by vanadate was always reversible.

If one accepts the possibility that the Ca pump is widespread in tissues and species[7], the vanadate inhibition of the Ca-ATPase activity in red cells and the ATP-dependent Ca efflux in squid axons could be taken as a strong suggestion that they are due to an identical process.

It is intriguing that whereas ouabain selectively inhibits the Na–K pump, vanadate inhibits both the Na–K and the Ca pumps. Vanadate almost certainly inhibits the Na–K pump by slowing the conformational change that precedes the release of K from the enzyme–potassium complex, $E_2(K)$, formed after dephosphorylation (refs 8, 9 and L. B. Karlish and I. M. Glynn, unpublished); in addition, external K is required for inhibition[8–10]. There is no indication as to the mechanism for vanadate inhibition of the Ca–ATPase, although Na^+ and Mg^{2+} are known to facilitate this inhibition[5]. The present experiments show that, similar to its effect on $(Na^+ + K^+)$ATPase, vanadate inhibits the Ca pump by acting at the intracellular surface. On the other hand, this inhibition was not dependent on external K (data not shown). Experiments are in progress to determine the sidedness of vanadate and cation interactions in the inhibition of the Ca pump in squid axons.

We acknowledge Professor R. L. Post for suggesting the use of vanadate. This work was supported by CONOCIT grant 51-0602.

A selectively driven molecular clock

Daniel Hartl & Daniel Dykhuizen
Purdue University, Department of Biological Sciences,
West Lafayette, Indiana 47907

The problem of whether mutations that increase a species' fitness are incorporated into the genome as a function of generation interval or as a function of absolute time is of some interest because of the clock-like nature of amino acid substitutions known to have occurred in the evolution of certain well studied proteins. The molecular clock features a rate of amino acid substitution that is relatively constant when averaged over a sufficiently long time, and the constant rate of substitution is independent of the generation interval of the species involved[1,2]. Furthermore, the variance in the rate of substitution is roughly twice the mean[2]. Some authors have argued that the very existence of a molecular clock implies that most amino acid substitutions must be selectively neutral or nearly neutral[3]. On the other hand, there is no compelling reason to assume that selectively driven gene substitutions would not also exhibit clock-like behaviour, in which case the rate of increase in fitness of a population should be a function of absolute time rather than generation interval. In this report, we have investigated the issue of rate of increase in fitness using initially isogeneic strains of *Escherichia coli* that had been allowed to evolve independently in glucose-limited chemostats[4] for 500 h. The nutrient supply was adjusted in such a manner that some of the strains maintained a doubling time of 2.5 h and others a doubling time of 5.0 h, and the relative fitnesses of the evolving strains were measured periodically. Our main conclusions are that (1) selectively driven gene substitutions detectable as increases in fitness do exhibit clocklike behaviour, (2) when averaged over a sufficiently long time, the rate of increase in fitness is a function of absolute time and independent of generation interval, and (3) except for an initial period related to adjustment to chemostat conditions, the variance in the rate of increase in fitness is very nearly twice the mean.

At each generation interval, two isogeneic strains were maintained in separate chemostats. One strain was DD616, which is sensitive to bacteriophage T5 (T5^S) and which carries *rpsL*, a non-reverting streptomycin-resistance mutation used to verify that the chemostats remained free of contamination; the other strain was selected as a spontaneous mutation in DD616 that confers resistance to T5 (T5^R), a phenotype associated with the *tonA* locus. Each chemostat contained 30 ml of medium and quickly reached an equilibrium density of about 5×10^8 cells per ml. Samples were withdrawn from the chemostats at 100-h intervals and aliquots containing approximately 10^{10} cells were frozen in 20% glycerol at −20 °C for subsequent study.

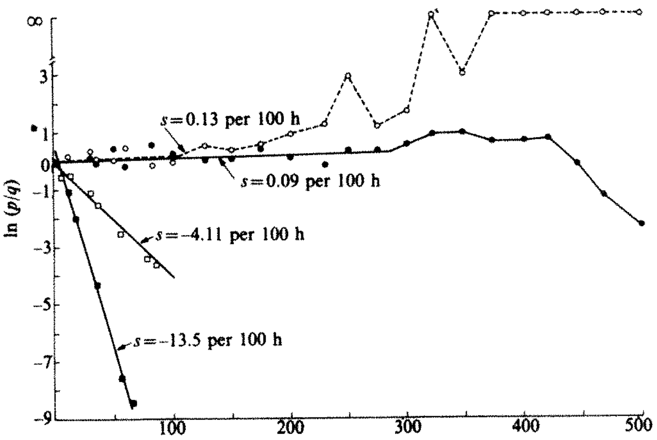

Fig. 1 Changes in the proportion of T5^R cells (p) relative to the proportion of T5^S cells (q) in chemostats. ●, Isogeneic T5^R and T5^S cells maintained at a 2.5-h doubling time. ○, Isogeneic T5^R and T5^S strains maintained at a 5.0-h doubling time. ■, Chemostat with 2.5-h doubling time containing unevolved T5^R strain against T5^S strain that had evolved for 200 h at a 5.0-h doubling time. □, Chemostat with 5.0-h doubling time showing genetic divergence between a T5^R strain grown for 300 h at a 2.5-h doubling time and a T5^S strain grown for 300 h at a 5.0-h doubling time.

The selective difference between any two strains was estimated by inoculating a glucose-limited chemostat with approximately 10^9 growing cells from each strain. The chemostat was maintained at either a 2.5-h or a 5.0-h generation time for 80–100 h, and at intervals the chemostat was sampled and the relative proportions of the two strains ascertained. The genetic marker used to distinguish the strains was resistance or sensitivity to T5, and chemostat samples were either plated on nonselective medium to estimate the total number of cells or were plated in the presence of an excess of T5 to estimate the number of T5^R cells; the ratio of T5^R cells to total cells estimates the proportion, p, of T5^R cells in the chemostat.

Selection in the chemostat is indicated by a systematic increase or decrease in the frequency of T5^R. Indeed, for a haploid population undergoing continuous growth[5], $dp/dt = pqs$, where $q = 1 - p$ represents the proportion of T5^S cells at

Table 1 Fitness differences observed per 100 h for strains that had evolved for various lengths of time in either 2.5-h or 5.0-h chemostats

	300		−11.91±0.21*	−3.60±0.26*	−1.70±0.13*	0.27±0.11	
	400		−10.10±0.40*		−2.31±0.31*	−1.10±0.17*	−0.23±0.30
	500		−10.94±0.29*			−0.88±0.15*	−1.42±0.17*

In each case the selection coefficient is that of T5^R relative to T5^S. Underlined values are means of two independent estimates that were not significantly different. All selection coefficients are estimated by the slope of a regression line, as shown in Fig. 1. * and † indicate values significantly different from 0 at 1% and 5% levels, respectively.

0028-0836/79/380230—02$01.00

time t, and s is the selection coefficient denoting that e^s is the rate of increase in the number of $T5^R$ cells relative to a value of 1 for the rate of increase of $T5^S$. Thus, $\ln(p_t/q_t) = \ln(p_0/q_0) + st$, so a plot of $\ln(p/q)$ against t is linear with slope s.

Figure 1 shows the selective equivalence of the original, unevolved $T5^R$ and $T5^S$ strains when grown in chemostats at 2.5 h (filled circles) or 5.0 h (open circles). These control chemostats were established at the same time as the experimental ones and were identical to them, except that the controls were inoculated with equal numbers of $T5^R$ and $T5^S$, and the frequency of $T5^R$ was periodically estimated. In the 2.5-h chemostat the frequency of $T5^R$ remained at very nearly 50% for 275 h; the slope of the linear regression from 0 to 275 h is 0.09/100 h and is not significantly different from 0. After 275 h the frequency of $T5^R$ begins to change somewhat erratically, a phenomenon caused by periodic selection[6]—the chance occurrence of rare, favourable mutations that carry the associated T5 marker with them as they change in frequency. The onset of periodic selection in the 5.0-h chemostat is earlier (125 h) and more pronounced, but the initial slope of the regression (0.13/100 h for 0–100 h) is again not significantly different from 0.

Results of the experiments are summarised in Table 1, which presents the selection coefficient in favour of $T5^R$ in competition experiments involving $T5^R$ and $T5^S$ strains that had evolved independently for various lengths of time. The upper and lower matrices refer, respectively, to strains evolved and tested at a 2.5-h and a 5.0-h generation interval. In these matrices the difference between any number and the number immediately below it represents the increment in fitness achieved in the corresponding 100 h of evolution; 100-h increments in fitness are also given by the difference between any number and the number immediately to its left.

Fitness increments calculated from Table 1 are presented in Table 2. Those increments which did not differ significantly from 0 were entered as 0 in Table 2. (The two negative entries in Table 2 are probably spurious, as the probability of obtaining one or more spurious significances at the 1% or 5% level with 44 tests is 36% and 90%, respectively.) As indicated in Table 2, considerable variation in the fitness increments occurs. The large values obtained for 0–200 h undoubtedly arise from the selection of favourable mutations present in the initial inoculum of 2×10^9 cells. The somewhat more regular behaviour of the fitness increments in the period 200–500 h represents long-term adjustment to the chemostat based on incorporation of newly arising mutations as evidenced by periodic selection in the controls. The overall average fitness increment per 100 h is 2.99 in the 2.5-h chemostat and 3.00 in the 5.0-h chemostat. In the 200–500-h period, the average fitness increments per 100 h are 1.55 and 1.10 in the 2.5-h and 5.0-h chemostats, respectively; these values are not significantly different.

Table 2 Fitness increments during various intervals of evolution in chemostats having either a 2.5-h(*a*) or a 5.0-h(*b*) doubling time

	0–100	100–200	200–300	300–400	400–500
a					
	12.91	0	0.72	4.32	0
	12.57	0	0	4.11	0
	15.22	0.78	0.80	5.03	0
		0.88	0	3.26	1.54
			0	2.34	1.19
	13.57	0.42	0.30	3.81	0.55
b					
	9.76	3.27	2.10	−1.81	0
	7.52	7.70	3.53	0	0
	3.09	9.74	3.17	1.37	1.19
		8.31	1.54	1.97	0.87
			1.90	1.21	−0.54
	6.79	7.26	2.45	0.55	0.30

Values were obtained from Table 1 by subtracting an entry from either the one immediately above it or the one immediately to its right. Differences not significantly different from 0 are entered as 0. Values beneath each column are unweighted means.

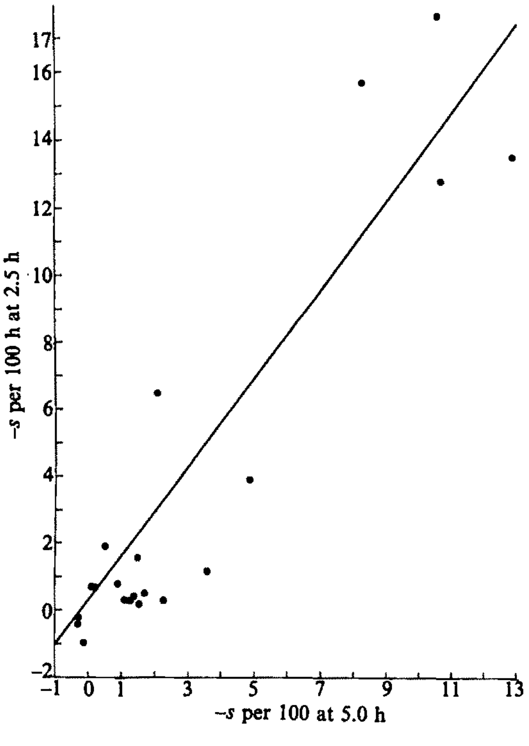

Fig. 2 Relationship between the observed fitness difference of two strains at a 2.5-h doubling time and the observed fitness difference of the identical strains at a 5.0-h doubling time. The regression is $y = 0.29 + 1.35x$.

Thus, when averaged over a sufficiently long time, the rate of increase in fitness under selection is constant and independent of generation time. However, the comparisons in Table 2 would be invalid if a given fitness increment at 2.5 h were magnified to twice its value at 5.0 h. In the worst case the regression of fitness increment at 2.5 h on fitness increment at 5.0 h would have a slope of 0.5, for then the values in Table 2*a* would have to be corrected by multiplying by a factor of 2, and the average fitness increments would then be a function of generation interval.

Figure 2 shows 21 cases where two strains were competed at both 2.5 and 5.0 h. The regression is $y = 0.29 + 1.35x$, where y and x represent the selection coefficients at 2.5 and 5.0 h, respectively; the linear regression on x accounts for 85% of the variation in y. The intercept, 0.29, has a standard error of 0.67 and does not differ significantly from 0, as expected. The slope, 1.35 (with s.e.m. 0.14), differs significantly from 0.5 but its 98% confidence interval includes 1. The comparisons in Table 2 that imply a selectively driven molecular clock are therefore justified.

As for the variance in fitness increments, attention should be restricted to the 200–500 h period to exclude the large effects in the first 200 h due to pre-existing mutations in the initial inoculum. For this period, the overall mean of the 30 increments in Table 2 is 1.33 per 100 h and the variance is 2.58. As the variance is very nearly twice the mean, the selectively driven fitness clock is remarkably similar to the molecular clock based on comparisons of amino acid sequences.

Macromolecular structural transitions in Pf1 filamentous bacterial virus

C. Nave, A. G. Fowler, S. Malsey, D. A. Marvin & H. Siegrist

European Molecular Biology Laboratory, Heidelberg, FRG

E. J. Wachtel

Department of Chemical Physics, Weizmann Institute of Science, Rehovot, Israel

The filamentous bacterial virus Pf1 is a simple model for biological filaments. We have studied the structure of the virion and report here that the helix parameters of Pf1 change sharply with temperature at about 8 °C. Local interactions between protein subunits change by only a few tenths of an ångstrom, but the changes are amplified between one end and the other of the virion to a rotation of 15 turns and a translation of 1,000 Å. The limited nature of the phase transition is probably due to the constraints of 'knobs-into-holes' interaction between side chains of adjacent α-helical protein subunits. Treatment of the virion with ether causes a rearrangement of protein subunits into sheets, with the α-helices normal to the plane of the sheet. This phase transition suggests a model for virion assembly in the bacterial membrane.

The Pf1 virion is a helical array of 46-residue α-helical protein subunits. It is 20,000 Å long by 60 Å in diameter, encapsulating a single-stranded circular DNA molecule at its core. Two types of X-ray fibre diffraction patterns from Pf1 have been obtained[1], both showing the same general distribution of intensity but each showing slightly different layer line positions (Fig. 1). Fibres prepared at room temperature show a pattern of layer lines indicating 4.40 units in one turn of the basic helix pitch, whereas fibres prepared at 4 °C show a pattern of layer lines indicating 4.46 units per turn (*u*/*t*). Although the local difference between the surface lattices of the two structures is slight, the effect is cumulative (Fig. 2), so that over the 20,000 Å length of the virion, the transition causes one end of the virion to rotate with respect to the other by about 15 turns, at the same time causing the length of the virion to change by about 1,000 Å. The same sort of change can be induced in a wet gel. When the gel is prepared at room temperature, it shows features typical of the 4.40 *u*/*t* diffraction pattern; when the temperature is reduced, features typical of the 4.46 *u*/*t* pattern appear within the minimum time necessary to obtain a diffraction pattern. The transition in the gel is reversible. We have varied many parameters other than temperature, including hydration of the fibre, *p*H, ionic strength, nature of monovalent or divalent cations present, and organic solvents, but so far we have found no other treatment that causes this transition at room temperature.

It is convenient to discuss this transition with regard to a specific molecular model. The simplest model of the protein subunit that explains the diffraction data is a gently curved α-helix rod about 70 Å long by 10 Å in diameter with its long

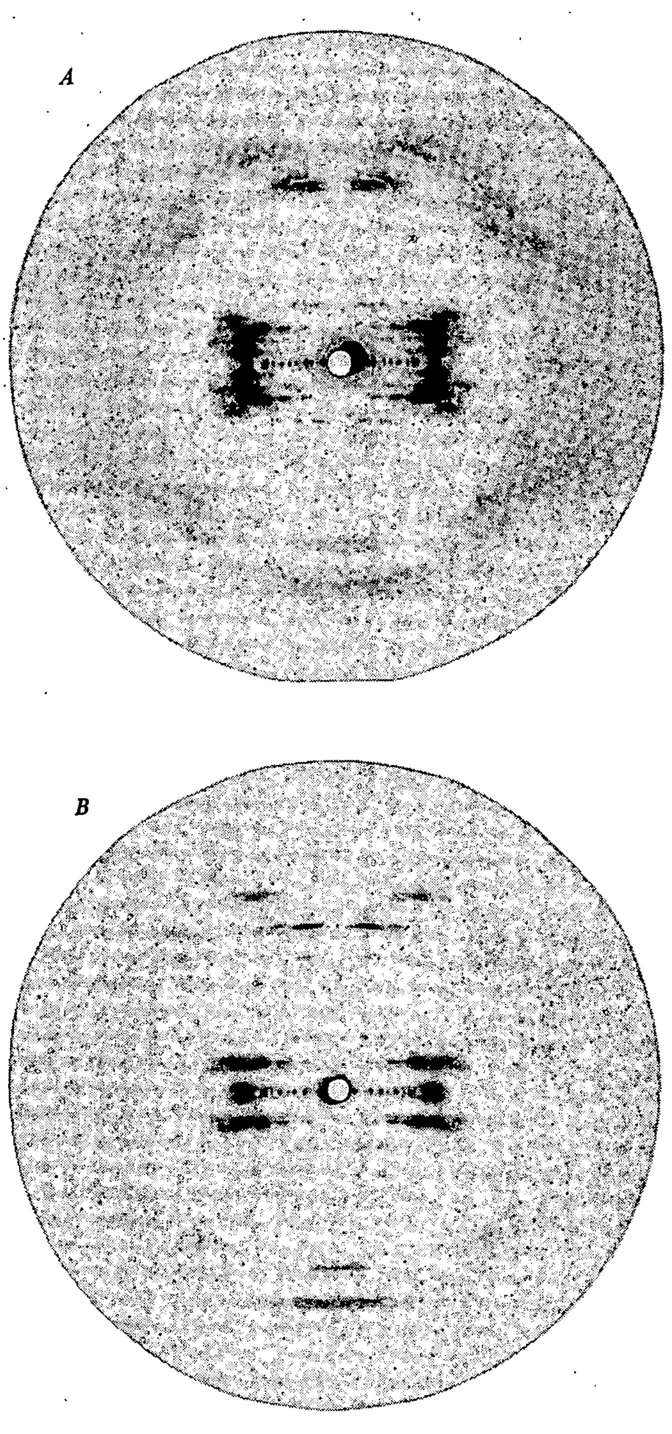

Fig. 1 X-ray diffraction patterns of Pf1 bacterial virus. X-ray fibre diffraction techniques have been described[20]. Fibres were prepared at the temperatures indicated, but X-ray patterns were taken at room temperature after the conformation had been fixed in the dried fibre. A strong magnetic field (6–7 T) was used to improve orientation of the α-helical virions in the fibres, following X-ray diffraction experiments by Samulski[21] and by J. Torbet in collaboration with us (report by Maret *et al.*[22]) showing that α-helices and Pf1 orient parallel to a magnetic field. The fibre axis (and the virion axis) is vertical. The broad distribution of intensity on the pattern gives information about the subunit shape. Strong regions of intensity in the equatorial (horizontal) direction at 10 Å and in the meridional (vertical) direction at 5 Å indicate that most of the protein in the virion is in the form of α-helix with the α-helix roughly parallel to the virion axis. The horizontal lines of intensity (layer lines) give information about the virion symmetry. Near-meridional spacings on layer lines at orders of 0.06385 Å^{-1} in the 4.40 *u*/*t* form and 0.06020 Å^{-1} in the 4.46 *u*/*t* form give the pitch of the basic helix as 15.66 and 16.61 Å, respectively. The positions of the other layer lines give information about the number of equivalent protein subunits in one turn of the basic helix. These other layer lines change position relative to the basic set as a result of the temperature-induced transition. Because of an inherent ambiguity in fibre diffraction patterns, it is not clear[3,4] whether the number of units per turn at room temperature is 4.40 or 5.40, but the detailed interaction between neighbouring subunits is virtually the same for the two alternatives, so this ambiguity does not affect the considerations discussed here. We choose 4.40 *u*/*t* for the purpose of discussion. *A*, 4.40 *u*/*t*, unit rise 3.56 Å, $a = 62.5$ Å, 92% relative humidity, specimen–film distance 7.50 cm, tilt 8°, disorientation half-width 2.3°. Fibre AF 12/2, prepared at room temperature, film 4055, ×0.98. The layer line splitting in the 5 Å meridional region can be approximately explained by a left-hand coiled-coil[5] of radius about 1 Å and pitch 150 Å. *B*, 4.46 *u*/*t*, unit rise 3.73 Å, $a = 61.9$ Å, 98% relative humidity, specimen-film distance 8.28 cm, tilt 12°, disorientation half-width 1.5°. Fibre AF 35/1, prepared at 4 °C, film 4158, ×0.9.

0028-0836/79/380232-03$01.00

axis oriented roughly parallel to the virion axis and also sloping radially[2]. Variants of this model have also been discussed[3]. Each subunit is in contact with neighbours 5 units and 9 units along the basic virus helix (Fig. 2). These contacts can be considered by imagining the axes of the α-helices to move smoothly along the 5-start or 9-start directions, so as to sweep out sets of twisted ribbons, or helicoids[2,4].

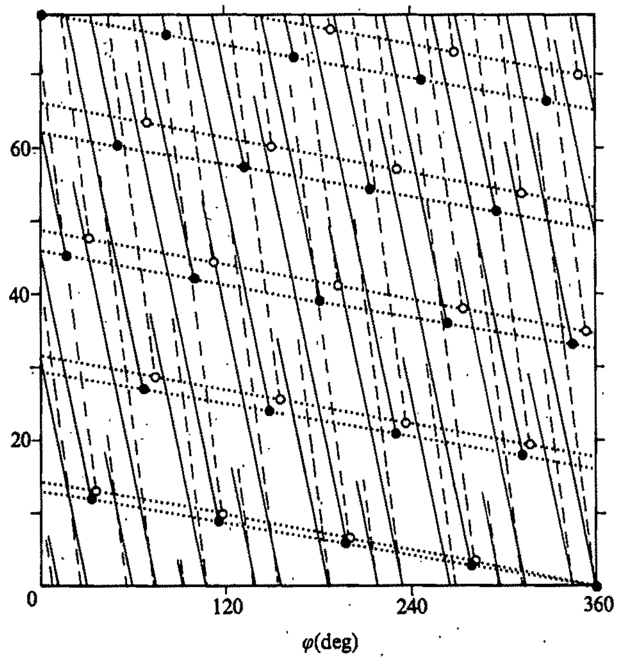

Fig. 2 Surface lattices of Pf1 helices with 4.40 u/t (filled circles and solid lines) and 4.46 u/t (open circles and dashed lines). The dotted lines indicate the basic helices. The surface lattice is generated by projecting equivalent points along radii onto a cylinder of 11.4 Å radius, and then cutting the cylinder vertically to give a two-dimensional representation. The circles represent the projections of equivalent points and the lines represent the projection of the α-helix axes.

Details of the model become less important if we discuss the changes in the structure during the transition rather than the absolute structures. The axis of the subunit in the 4.46 u/t model is more nearly parallel to the axis of the virion than in the 4.40 u/t model (Fig. 2), but the shape of the protein subunits and the interactions between them remain virtually unchanged during the transition. The close relationship between the two structures can be seen by comparing the diffraction data from the strong J_5 and J_9 layer lines of the two structures (Fig. 3*A* and *B*). Although the ζ (vertical) positions of these layer lines change as a result of the transition, because of the change in helix symmetry, the intensity distributions along these layer lines (which reflect the molecular structure of the subunit) show virtually no change. The similarity between amplitudes predicted for the two models (Fig. 3*C* and *D*) is comparable to the similarity between amplitudes observed in the diffraction experiment. Large changes within the subunit, such as bending at a hinge, are not supported by the data. Very small and subtle changes in neighbour–neighbour interactions are sufficient to explain the observations. In particular, the fit of side chains of one subunit into the space between side chains of its neighbours ('knobs-into-holes')[5] is unchanged. This similarity was defined more precisely by calculating distances between pairs of β-carbons on neighbouring subunits where the β-carbons approach one another to within 5 Å. The specific pairs of atoms involved in such contacts do not alter between the 4.40 u/t and the 4.46 u/t models, and even the absolute distances between atoms in these pairs change by only a few tenths of an ångstrom.

The transition appears to be discontinuous and limited. That is, no intermediate forms between 4.40 u/t and 4.46 u/t have been observed, and no other forms have been observed outside these two extremes. The limitation follows directly from consideration of the knobs-into-holes packing in the model. Knobs-into-holes interactions constrain the crossing angle between the axes of neighbouring α-helices[5]. Ideal α-helices with an internal rotation per residue of 100° will cross at an angle of 20°. If the crossing angle changes from 20°, the internal rotation per residue must change correspondingly. However, stereochemical constraints limit the rotation per residue to within a degree or so of 100° (ref. 6), so crossing angles of roughly parallel helices are near 20° (ref. 7). Packing between neighbouring α-helical subunits in the Pf1 model is also constrained by knobs-into-holes considerations[2]. In order to retain unchanged knobs-into-holes packing during the transition from a 4.40 u/t to a 4.46 u/t model, the rotation per residue within the α-helix must be changed by about 0.5°. The absence of virions with less than 4.40 u/t or greater than 4.46 u/t can then be explained as a result of a limitation on internal twist within the α-helix that is coupled by knobs-into-holes packing to the number of units per turn in the virion. This same constraint was shown in a different

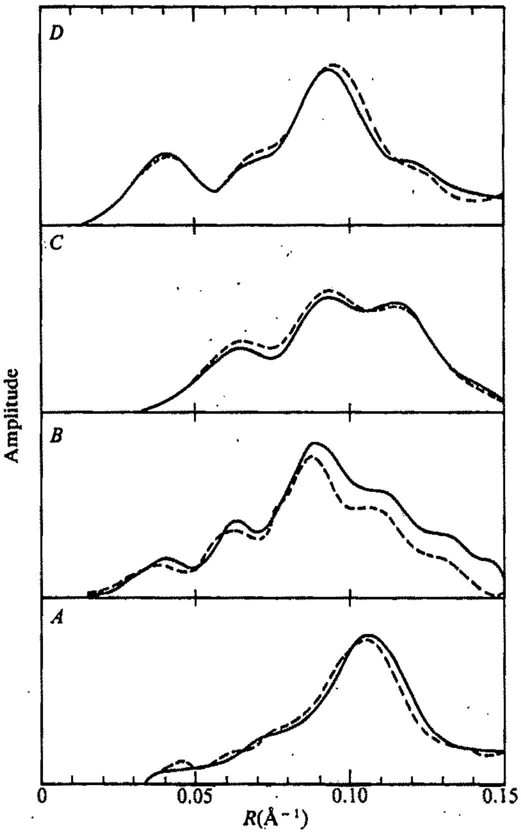

Fig. 3 Distribution of diffraction amplitude along layer lines in the strong 10 Å near-equatorial region. Solid curves represent 4.40 u/t amplitudes and dashed curves represent 4.46 u/t amplitudes. Intensity measurements and Fourier transform calculations have been described[2]. The models have side chains attached in the most probable conformation to the α-helix backbone[2]. The two strongest contributions of intensity in the 10 Å region are due to the periodicities of the 5-start and the 9-start helicoids, which are expressed in the helical Fourier transform as the J_5 and J_9 Bessel functions. The agreement between calculated and observed amplitudes over the whole diffraction pattern is similar to that of previous models[2]. The remaining differences between calculated and observed amplitudes are of the order usually found in fitting models to fibre diffraction data, and do not affect our discussion. *A*, Observed amplitude for the J_9 layer line. 4.40 u/t data for the layer line at $\zeta = 0.0128$ Å^{-1} (fibre AF 12/2, film 4055) and 4.46 u/t data for the layer line at $\zeta = 0.0046$ Å^{-1} (fibre AF 35/1, film 4158). *B*, Observed amplitude for the J_5 layer line. 4.40 u/t data for the layer line at $\zeta = 0.0383$ Å^{-1} and 4.46 u/t data for the layer line at $\zeta = 0.0278$ Å^{-1}. Film numbers as in *A*. The apparent discrepancy between the two curves beyond 0.1 Å^{-1} is due in part to the contribution of the J_{17} Bessel function, which cannot be resolved from J_5 in the 4.40 u/t data but is resolved (and not included) on the 4.46 u/t data. *C*, Calculated amplitude for the J_9 layer line (ζ as in *A*). *D*, Calculated amplitude for the J_5 layer line (ζ as in *B*).

way using a non-convergent energy minimisation technique which gave a local minimum for a series of models in the region of the transition[1].

Stereochemical constraints satisfactorily explain the limited nature of the transition, but they do not directly explain why the transition is driven by temperature. It is apparent that the stability of the 4.46 u/t helix relative to the stability of the 4.40 u/t helix changes with temperature. This effect could be due to temperature-dependent terms in the molecular interaction potentials controlling contact distances or patterns of attraction and repulsion between side chains. Changes in the interaction potentials could alter either the internal twist of the α-helix or the details of knobs-into-holes packing.

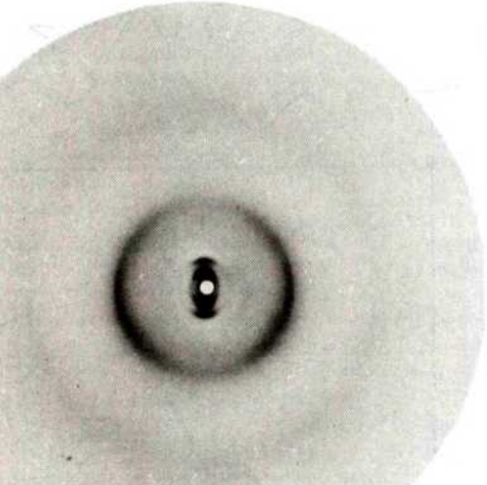

Fig. 4 X-ray diffraction pattern of ether-induced sheets of Pf1 bacterial virus. Plane of the sheet is horizontal. Sheets were prepared by shaking a purified solution of Pf1 at 5 mg ml^{-1} for 120 min at room temperature with an equal volume of ether[4]. The sheets were centrifuged at 30,000 r.p.m. for 3 h at 15 °C in the Beckman SW 50.1 rotor, and resuspended at a concentration of 25 mg ml^{-1} in 0.005M Tris-HCl, *p*H 8.1. A 0.5 ml drop of the concentrated solution was placed on a silicone-treated glass slide[23] and allowed to dry at 100% relative humidity, 4 °C, for 160 h in a 7-T magnetic field, with the plane of the slide perpendicular to the magnetic lines of force. A thin slice of the drop was cut free from the slide and mounted in the X-ray diffraction camera with the X-ray beam parallel to the plane defined by the slide. The sharp vertical reflections are at orders of 55.6 Å; on some patterns reflections up to the fifth order have been observed. The strong region of intensity in the horizontal direction is at 9 Å. Sample AF 33/2, film 4146, 75% relative humidity, specimen-film distance 7.4 cm, ×1.0. The same sample at 98% relative humidity expanded slightly to give sharp vertical reflections at orders of 60.1 Å.

Solvent is likely to play an important part in such phenomena. Even internal structure may be affected by solvent. Hydration behaviour can be subdivided[8] into ionic or electrostatic effects, hydrogen bonding of water to the solute, and hydrophobic effects. All of these are temperature dependent to some degree, and may play some part in the Pf1 transition. The electrostatic effect[9] is an especially likely candidate for the structural transition in Pf1. Theoretical calculations show that the dielectric constant of the solvent has an important effect on the conformation of proteins[10]. The dielectric constant of water increases as the temperature is reduced[11]. In the presence of glycerol (which has a dielectric constant about half that of water), the 4.40 u/t form is maintained even when fibres are made at 4 °C. This fact is consistent with the idea that the temperature-induced conformational change is due to the increase in the dielectric constant of the medium with decreasing temperature. Special cryosolvents[12] that have been developed to counteract the effect of temperature on *p*H may be useful to study the structural transition in Pf1.

It is possible that the system is instead controlled by entropy effects, resulting from vibration or libration of the protein molecules. Calorimetry could distinguish between the two possible mechanisms.

More dramatic changes in Pf1 structure can be induced by brief treatment with ether. The virions swell to hollow cylinders about three times their original diameter but only one tenth the normal length[13]; further treatment leads to flat sheets of protein[4]. X-ray diffraction studies of oriented stacked sheets show a strong 9 Å region of intensity in the direction parallel to the plane of the sheet, and sharp reflections at orders of about 55–60 Å in the direction perpendicular to the plane of the sheet (Fig. 4). This kind of diffraction pattern is expected if the Pf1 α-helical coat protein subunits are oriented with their long axes roughly perpendicular to the plane of the sheet. If the 46-residue α-helices were oriented exactly perpendicular to the sheets, the sheets would be 70 Å thick, but if some of the neighbour–neighbour side chain interactions in the sheet are the same as in the 5-start helicoids of the virion, the α-helices will be slightly skew and the sheets will be only 50–60 Å thick. The 9 Å spacing in the plane of the sheet corresponds to the distance between adjacent α-helices. Patches of coat protein in the bacterial membrane with the α-helical protein spanning the 50 Å thick membrane have been proposed as precursors of virus assembly[2,14–16]. These pure viral protein sheets are useful models for the study of assembly of the virion.

The Pf1 virion is an example of a system in which small local changes in molecular structure are amplified into large reversible changes in a molecular assembly. The changes within the α-helix subunit between the 4.40 u/t and the 4.46 u/t models are similar in magnitude to the calculated room temperature vibrations within an α-helix[17]. At the transition temperature, Pf1 will be delicately poised between the two structural forms, and little energy would be required to induce an oscillation between the two forms. This type of induced oscillation between two structural forms of an α-helical assembly could generate a travelling wave in other α-helical assemblies such as myosin or membrane pores[18,19].

Nuclear magnetic resonance is a technique which permits direct observation of the Watson–Crick hydrogen-bonded ring imino protons (guanine N_1H and thymine N_3H). As the formation and disruption of hydrogen bonds of double-helical RNA and DNA structures are key events during various biological processes, NMR thus provides a useful tool for studying the fluctuational mobility of the individual base pairs. Indeed, several NMR studies of oligo- and polynucleotides have been carried out to probe the structure and dynamics of nucleic acids in solution (for a review see ref. 1). The present study constitutes the first part of our attempt to assess the influence of non-complementary base pairs on the stability of nucleic acid double helices. We report the spectral assignment and temperature-dependent NMR profiles of the hydrogen-bonded imino protons of the two DNA fragments shown in Fig. 1. The assignment is based solely on experimental grounds using the principle of chemical modification. It will be demonstrated that the introduction of a non-complementary (wobble) base pair in a DNA duplex introduces an extra melting site in addition to the sequential melting which starts with the terminal base pairs in the double helix structure.

The oligodeoxynucleotides were synthesised using an improved phosphotriester approach[2]. Full details of preparation and purification will be published elsewhere[3]. Figure 2 presents the high-resolution 360 MHz ^{1}H-NMR spectrum between 12.0 and 14.5 p.p.m. of fragment 12 in H_2O as a function of temperature. Sequential linewidth and intensity changes with increasing temperature allow assignment of all signals to specific NH-Watson–Crick hydrogen-bonded protons[4]. At low temperatures (−3.5 °C) six resonances, two of which coincide at ~13.3 p.p.m., are observed. On raising the temperature the intensity of the signal at 13.3 p.p.m. falls from two to one proton, identifying that the faded signal as the fraying terminal A·T base pair 1. Between 10 and 30 °C the resonance at 13.8 p.p.m. gradually disappears and is therefore assigned to A·T base pair 2. The signal at 12.5 p.p.m. is next to follow (G·C base pair 3). At 52 °C only three signals remain. As G·C base pairs resonate at ~1 p.p.m. to higher field than corresponding A·T base pairs[5], the signal at 12.7 p.p.m. is assigned to the G·C base pair 4. Increasing the temperature to 56 °C results in the disappearance of all resonances indicating that the breaking of the last six base pairs is an 'all or none' process. The two A·T base pairs 5 and 6 can be assigned unambiguously by comparing the low temperature spectra of fragment 12 and fragment 13 (Fig. 3). In the spectrum of fragment 13 five out of six signals in the range of 12–14 p.p.m. display virtually the same chemical shifts as found in fragment 12; it is therefore concluded that the two fragments have similar conformations for the base pair sequence 1–5 and that the same assignment holds for fragment 13. The important difference, however, between the spectra of the two fragments is a large downfield shift of one of the resonances at 13.3 p.p.m. in fragment 12 to 14.3 p.p.m. in fragment 13. This shift is obviously due to the effect of separating base pairs 6 and 6′ by insertion of a T–T pair. The insertion moves the imino proton of base pair 6 away from the shielding cone of the A·T base pair 6′ and vice versa. Therefore, the resonance at 14.3 p.p.m. (and one of the resonances at 13.3 p.p.m. in fragment 12) is assigned to base pair

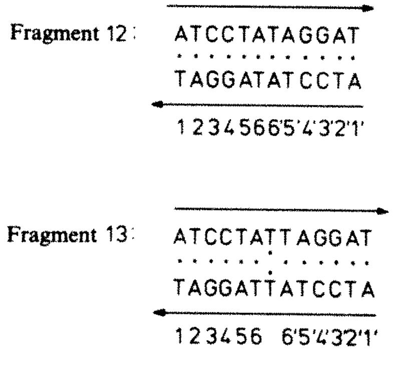

Fig. 1 Base sequence of the self-complementary deoxyoligonucleotides studied. Base pair numbering as shown; they are equivalent pairwise because of the two-fold symmetry of the double helix.

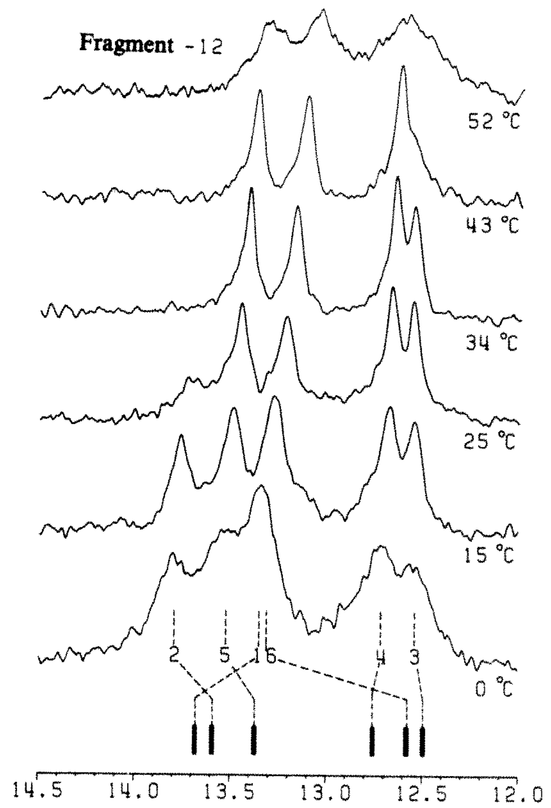

Fig. 2 Low-field region of the 360 MHz ^{1}H-NMR spectra of fragment 12 at various temperatures. Only a representative (6 out of 15) set of spectra is shown. The solid lines (bottom) represent the calculated shifts (see text) for the hydrogen-bonded imino protons in a B-DNA helix. The NMR samples were prepared by dissolving ~3 mg of the oligodeoxynucleotide in 270 µl of a buffer solution containing 0.5 M NaCl, 0.1 M sodium cacodylate (*p*H 7.0) and 5% v/v D_2O. High resolution proton NMR spectra were recorded on a Bruker HX-360 NMR spectrometer interfaced with a BNC-12 computer system and equipped with a standard temperature unit, using micro NMR sample tubes with a cylindrical cavity. The spectrometer was operated in the correlation mode[14], using an internal deuterium field/frequency lock. Chemical shifts were measured relative to the solvent H_2O peak and converted to DSS reference by correcting for the H_2O to DDS chemical shift using the appropriate temperature calibration curve. All reported shifts are denoted using the δ-convention, that is, positive values represent shifts to lower field.

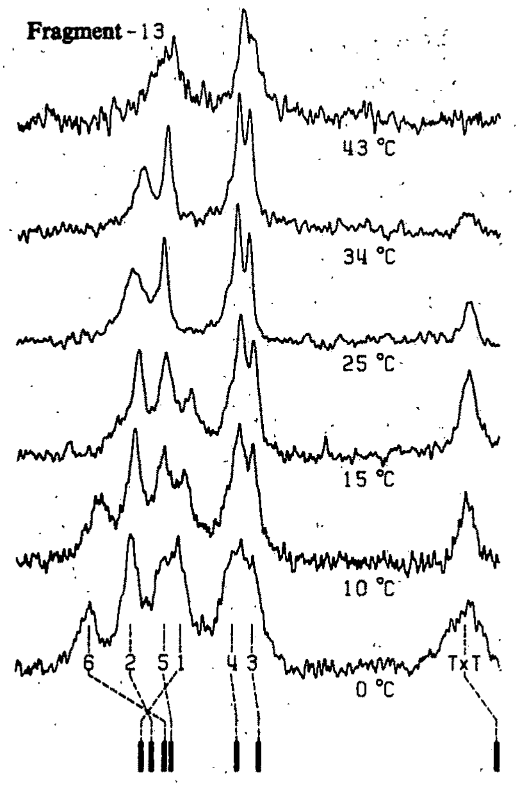

Fig. 3 Low-field region of the 360 MHz ^{1}H-NMR spectra of fragment 13 at representative temperatures. For further details see Fig. 2 legend.

6, and thus the remaining signal at 13.6 p.p.m. can be ascribed to base pair 5. An extra signal is displayed by fragment 13 at relatively high field (10.3 p.p.m.), which is assigned to the non-hydrogen-bonded imino protons of the thymidylyl residues in the middle of the strands. The temperature profile of fragment 13 is consistent with this assignment, but shows two 'melting sites' instead of one (see below).

It is now generally recognised that oligodeoxynucleotides tend to take up a B–DNA-like conformation in aqueous solution[6–8]. The computer program CARSHI (written in FORTRAN IV, using the parametrisation of Giessner–Prettre and Pullman[9]) was used to calculate the ring current shielding due to the nearest and next-nearest neighbouring base pairs in a B–DNA double-helical structure[10]. These values were added to the estimate chemical shift for 'isolated' Watson–Crick base pairs[5] ($\delta_{G-C}=13.6$ p.p.m.; $\delta_{A-T}=14.6$ p.p.m.), yielding the calculated shifts shown as solid lines in Figs 2 and 3. To determine the chemical shift of the 'free' (non-hydrogen-bonded) imino proton of a thymine residue the spectra of thymidine 5′-*O*-methyl phosphate and of d(TTTT) were recorded at 0 °C (~3 mM, *p*H = 7). Both compounds displayed a very broad resonance at 11.2 p.p.m., which sharpened when the exchange rate was suppressed by lowering either the temperature (to −9 °C) or the *p*H (to 4.0).

The agreement between calculated and observed chemical shifts seems reasonable, taking into account the possible and unknown effects of residual fraying and/or small deviations from the accepted B–DNA structure. However, it is clear that assignment of resonances close to one another on the basis of ring current shift calculations must be regarded with caution.

Fragment 12 represents the first oligodeoxynucleotide studied by nuclear magnetic resonance in which A·T base pairs in the middle of the strands are flanked on both sides by G·C base pairs. A·T-rich regions are known[11] to be thermally less stable than G·C-rich regions in long DNA fragments. One could therefore expect that the central A·T region in fragment 12 would 'melt out' before the G·C pairs disappeared. This is not the case; our experiments clearly indicate that all four central A·T base pairs in fragment 12 remain intact until the last G·C base pairs 4 and 4′ are disrupted. Therefore, we conclude that a 'G·C protected' sequence of four A·T pairs is too short for such a local destabilisation of the duplex.

For fragment 13, it is certainly important to determine whether the T–T pair loops out from the helix or whether it forms a wobble pair. The present experiments give the following pertinent information: the chemical shift of the T–T imino protons are ~1 p.p.m. to higher field than that observed for the 'free' imino proton of a thymine residue (see above). This large value for the upfield shift requires that this 'free' imino proton is positioned in the shielding cone of the neighbouring adenine base. Therefore, we propose that fragment 13 has a marked tendency to form a continuous, regular B-DNA-like structure with a T–T wobble pair embedded in the middle of the helix. Shift calculations agree well with this proposition (Fig. 3). Interestingly, a similar occurrence was recently reported in a temperature-jump study[12] of anticodon–anticodon interactions between various tRNAs. It was found that the U–U wobble in the middle position of the interacting codons behaves in a unique way in the sense that it apparently does not oppose the formation of stable complexes, whereas the other mismatches tested (C–C, A–A, G–G, G–A, C–A) seem to prohibit complex formation. Thus, the continuity of the DNA double helix with a T–T wobble pair may be found to be an exception rather than a rule, but further work is necessary to clarify this point.

The temperature profile of fragment 13 displays several interesting features. Compared with fragment 12, the NMR melting temperature is lowered by ~11 °C, indicating that the insertion of the T–T wobble pair significantly lowers the overall stability of the double helix. This observation agrees with thermal elution studies of oligodeoxyadenylates on cellulose-pdT$_9$. The replacement of an internal dA- by a dT-residue lowered the elution temperature (which is compatible with the T_m obtained from solution thermal denaturation studies) by about 15 °C (ref. 13). An explanation of this phenomenon may be inferred from Fig. 3. The resonances of the T–T wobble pair and A·T base pair 6 located in the middle of the double-stranded structure vanish within the same temperature range as the terminal A·T base-pair 1. This implies that the wobble introduces an extra melting site in the double-helical structure. Thus, the breaking of the Watson–Crick hydrogen bonds occurs on both sides of the two G·C pairs, causing fragment 13 to be destabilised relative to fragment 12.

This study clearly demonstrates that high-field nuclear magnetic resonance techniques combined with 'tailor-made' oligonucleotides significantly increases our understanding of the structural features and dynamics of this type of important biological model compound.
